THE CANADIAN ENGINEER

Head Office, 62 Church St., TORONTO

MONTREAL WINNIPEG

INDEX TO VOLUME 22.

TA
1
C34
V.22

JANUARY to JUNE, 1912.

NOTE.—Where figures run below 100 they refer to number of issue and page; where they run over 100 they refer to pages only. *Ex.*:—Apartment Houses, Edmonton.....5, 60 indicates that subject will be found in Issue No. 5, on page 60. *Ex.*:—Agreement Writing.....271, 324, 351, etc. indicates subject will be found on pages 271, 324, 351, etc.

AUTHORS.

	PAGE
Ablett, C. A.	331
Adams, Henry	239
Allaire, Alex.	188
Allen, Chester S.	459
Altham, C. H.	837
Anderson, G. R.	449
Angier, F. J.	385
Annan, C. L.	763
Armstrong, J. W.	328
Aston, R. Godfrey	663
Bacon, Chas. G.	443
Balch, L. R.	687
Barnes, H. T.	862
Bateman, G. C.	815
Bell, Jas. S.	356
Biggar, E. B.	215
Boehck, R. E.	771
Bolling, Chas. E.	320
Bowman, H. J.	341
Browne, David H.	115
Brown, E. 162,	237
Carpenter, H. C. H.	389
Case, Gerald O.	590
Chipman, Willis	610
Cliver, McGarvey	267
Code, S. B.	117
Coldwell, O. B. 633,	660
Cooley, Prof. Mortimer E.	630
Cosby, Col. Spencer	520
Cowie, Fred. W.	178
Crosby, W. W.	250
Cross, Dr. Walter M.	537
Cunningham, F. L.	220
Cushing, W. C.	414
Dalstrom, O. F.	233
Dedrick, B. W.	646
Eckardt, H. M. P.	122
Eden, E. M.	220
Farmer, F. B.	619
Farmer, J. E.	111
Fawkes, A. W. Ellson	505
Field, Frd. E.	191
Finch, A. H. 708,	722
Finley, W. H. 677,	696
Fitzgerald, F. A. J.	618
Flack, Dr. Martin	512
Flinn, Alfred D.	205
Fort, E. J.	644
Friedlaender, E.	627
Gaehr, D.	388
Gardner, Henry A.	751
Gassman, H. M.	768
Gibbs, George	604
Gibson, Thos. W.	147
Gillies, A.	337
Goss, W. F. M.	852
Griswold, F. M.	865
Groves, E. W.	789
Gugielminetti, Dr.	549
Haanel, B. F.	602
Haggander, G. A.	477
Hatch, Frederick N.	639
Haultain, H. E. T.	143
Heafield, R. W.	523
Hedley, Robert R.	139
Hering, Carl	528
Hill, Dr. Leonard	512
Hill, Nicholas S., Jr.	125
Hill, Stirling B.	703
Hoffman, I. W.	204
Hotchkiss, L. J.	596
Howard, James E.	551
Icke, John F.	479
Jackes, Lyman	370
James, E. A. 170, 346,	834
Johnson, F.	389
Jones, L. M.	285
Kaufman, Gustave	679
Kennedy, H. J.	148
Kensit, H. E. M. 144, 218, 254,	275
Knight, Ray R.	257
Lederer, Dr. Arthur	407
Leggett, R. M. 501,	509
Lewes, Prof. C. B.	586
Ludlow, T. W.	172
McCormick, Bradley T.	827
McKenn, R. J.	756
McLean, W. A. 133,	353
Murray, T. Aird	470
Nasmith, Geo. G.	386
Nelson, E. E.	598
Okes, Day I.	568
Owens, Dr. John S.	553
Oxley, A. C.	642
Perkins, Dr. R. G.	500
Pfoser, A.	558
Philip, Arnold	389
Piepmeier, B. H.	485
Pratt, R. Winthrop	499
Primrose, J. S. Glen	280
Printz, Carl J.	838
Provost, A. J.	644
Purdue, A. H.	803
Reichmann, Albert	569
Richards, Prof. Joseph W. 556,	650
Richards, W. H.	466
Richarme, E.	649
Rose, W. N.	220
Ross, Malcolm N.	456
Ruthrauff, F. H.	583
Saville, Chas.	785
Sells, Fred S.	411
Sifton, Hon. Clifford	137
Smith, Prof. Albert	374
Sperling, Godfrey	578
Swan, W. G.	393
Switzer, J. A.	381
Tennant, D. C. 533,	655
Teran, C.	412
Thompson, Sanford E. 451,	494
Thomson, T. Kennard	311
Thronley, J. H.	398
Tissington, F. 423, 606,	824
Tripp, Guy E.	513
Turnbull, R.	616
Tyrrell, H. G. 847,	685
Vincent, D. D.	510
Warde, Thos. J.	211
Watts, Oliver P.	588
Wheaton, W. R. 296,	590
Wheelock, C. R.	96
White, Arthur V.	77

Young, C. R., 271, 324, 351, 378, 436,	491

BOOK REVIEWS.

	PAGE
A B C of Hydrodynamics, R. de Villamil	472
A New Analysis of The Cylinder Performance of Reciprocating Engines. J. P. Clayton	871
Analytical Mechanics	223
Applied Methods of Scientific Management, F. A. Parkhurst	584
American Transportation Question, S. O. Dunn	584
Canadian Almanac, The	223
Centrifugal Pumping Machinery, C. G. de Laval	741
Clay and Shale Deposits of N. S.	225
Concrete Bridges, Culverts and Sewers. A. A. Houghton	585
Concrete in Cold Weather	360
Concrete Costs. F. W. Taylor and S. F. Thompson	870
Constructing Concrete Porches. A. A. Houghton	584
Corrosion of Iron and Steel, The. J. N. Friend	471
Design of Electrical Machinery. W. T. Ryan	870
Dredges and Dredging. Chas. Prelini	741
Drill Work, Methods and Cost. R. R. Sanderson	742
Economies of Contracting. D. J. Hauer	360
Economy Steam Turbine for Belt Drive, The	871
Efficiency. H. Emerson	358
Elementary Principles of Reinforced Concrete Construction. E. S. Andrews	585
Elements of Engineering Estimating. A. Suggate	742
Elements of Structures, The. Geo. A. Hool	472
Engineering as a Vocation. E. McCullough	358
Five Thousand Facts About Canada for 1912. F. Yeigh	472
Geodetic Surveying. Ed. L. Ingram	358
Heat and Thermodynamics. F. M. Hartman	471
Highway Engineering. A. H. Blanchard	360
Home Waterworks	222
Industrial Drawing and Geometry. H. J. Spooner	472
Investigation of the Strength of Rolled Zinc, An. H. F. Moore	359
Law Relating to Engineering, The. L. W. J. Costello	358
Manual of Civil Engineering Practice. F. Knowles Taylor	742
Mechanics of Materials	223
Mining Without Timber. R. B. Brinsmade	359
Modern American Telephony	224
Pipes and Tubes, P. R. Björling	359
Practical Cement Work	224
Practical Chemistry for Engineering Students. A. J. Hale	585

*Illustrated.

	PAGE
Practical Gyrostatic Balancing. Herbert Chatley	742
Precise Calculations of Pipe Drain and Sewer Dimensions. C. E. Housden	585
Principles of Specification and Agreement Writing. C. R. Young	742
Reinforced Concrete Buildings. Ernest L. Ransome	740
Reinforced Concrete Construction in Theory and Practice. H. Adams and E. R. Matthews	471
Reinforced Concrete Design Simplified. John C. Gammon	742
Retaining Walls for Earth. M. A. Howe	360
Roofs and Bridges, Part III., Bridge Design. M. Merriman and H. S. Jacoby	361
Sewage Disposal. Geo. W. Fuller	740
Sewage Lifting Apparatus	225
Sewage Sludge	470
Ship Wiring and Fitting	224
Short Course in Graphic Statics. W. L. Cathcart and J. I. Chaffee	742
Signal Dictionary, The	472
Standard Forms of Field Notes for Civil Engineers. C. C. Anthony	472
Starting Currents of Transformers. T. D. Yensen	584
Steam Power Plants. H. C. Meyer	361
Street Lighting. J. M. Bryant and H. G. Hake	359
Strength of Materials, James E. Boyd	358
Structural Engineering	222
Superheated Steam in Locomotive Service, W. F. M. Goss	870
Suspension Bridges and Cantilevers. D. B. Steinman	740
Synchronous Motors for Power Factor Correction	472
Tests of Columns. A. N. Talbot and A. R. Lord	584
Tests on Reinforced Concrete Columns. M. O. Withey	359
Theory and Practice in Designing	222
Theory and Practice of Technical Writing, The	222
Treatise on Hydraulics. Mansfield Merriman	742
Tunnel Shields and the Use of Compressed Air in Sub-Aqueous Work. W. C. Copperthwaite	741
Twelve Principles of Efficiency, The. H. Emerson	358
Valuation of Public Utility Properties. Henry Floy	741
Waterpowers of Canada, The	224

CONTRACTS.

Apartment House, Edmonton 5,	60
Apartment House, Victoria 5,	60
Asphalt Cement, Winnipeg 16,	62
Bascule Steel Bridge 8,	60
Breakwater 2,	59
Breakwater; Dredging, Meaford, Ont. 10,	60
Breakwater, St. John, N. B. 21,	62
Bridge, Bow River, Alta. 8,	60
Bridges, Burnt River, Ont. 8,	60
Bridge 2,	60
Bridge, St. Andrew's Locks, Winnipeg 20,	62
Buildings, Steel Co., Hamilton 4,	60
C. P. R. Building, Edmonton 14,	62
C. P. R. Subway, Moose Jaw, Sask. 20,	62
Cast Iron Water Pipe, Prince Albert, Sask. 12,	62
Cement Plant, Tod Inlet, V.I. 3,	76
Cement Sidewalks, Battleford ..18,	60
Cement Walks, Kamloops 21,	62
Chain Drives, Montreal 15,	62
Church, Calgary 9,	60
Concrete Mixer, Toronto 12,	62
Concrete Walk and Curbing, Saskatoon 11,	60
Connaught Public School, Toronto, 14,	60
Court House, Newcastle, N.B. 23,	70
Crushed Rock for Road Work, Vancouver 11,	60
Dam, Calgary	728
Dams and Excavation Work, Surrey, B. C. 14,	60
Depot, Vancouver 23,	70
Dock, C. N. R., Port Arthur 16,	60
Dock, Port Arthur 16,	60
Electrical Unit, Kenora, Ont. ...18,	60
Elevator, Brandon 23,	68
Elevator, C. P. R., Port Arthur ..13,	60
Elevator, Port McNicholl 6,	60
Ex. to Breakwater, Devil's Island, N. S. 10,	60
Freight Shed, C. P. R., Weyburn, Sask. 14,	62
Garage, Winnipeg, Man. 15,	62
Generators, Regina 24,	68
G. T. P. Terminals, St. John, N.B. 7,	60
Gravel Washing and Rock Crushing Plants, Vancouver 9,	60
Harbor Improvements, St. John...2,	60
Hibben Block, Victoria 8,	60
Hotel, C.P.R., Calgary 9,	60
Hudson Bay Railway 7,	60
Hydrants, Vancouver 12,	62
Hydro-Electric Unit, Stave Falls, B.C.	308
Incinerator, Strathcona 6,	60
Irrigation Block, Calgary 20,	60
Jetty, Fraser River, B.C 10,	60
Lake Shore Road, Toronto 12,	62
Library, Edmonton 6,	60
Machinery Hall, Ottawa 16,	60
Newmarket Canal Bridges 8,	60
Nile Bridge, Cairo 6,	60
Office Bldg. for Alberta Land Co., Port Arthur 14,	60
Offices, etc., Montreal 4,	60
Pavement, Humber Bridge to Mimico, West Toronto 14,	62
Pavement, Saskatoon 16,	60
Pavements, Vancouver 20,	62
Paving, Calgary, Alta....15, 60, 15,	62
Paving, Edmonton 19,	62
Paving, Moose Jaw 22,	64
Paving, Saskatoon 9, 60, 11,	60
Paving, Windsor 17,	64
Pier, Gimili, Man. 3,	76
Piers, G. N. W., Vancouver 15,	62
Piggott Tank 8,	60
Pipe Laying, etc., Regina, Sask., 15,	62
Portland Cement, Saskatoon 13,	62
Power House, Niagara Falls 4,	60
Power Scheme, Lacolle Falls 18,	62
Public Building, Lloydminster, Sask. 10,	60
Pulp & Paper Mill, Thorold, Ont., 22,	64
Quebec Water Mains 5,	60
Reservoir, Berlin 24,	68
Reservoirs, Edmonds, B. C. 23,	68
Reservoir, Kamloops, B. C. 12,	62
Reservoir, Moose Jaw 18,	60
Road Machinery, Welland 17,	64
School, Calgary 16,	60
School, Lethbridge 16, 60, 22,	64
Sewerage, Kerrisdale, B. C. 23,	68
Sewage Disposal Works, Lethbridge 2,	59
Sewer, Balaclava St., Vancouver, 15,	62
Sewers, Kerrisdale, B. C. 19,	64
Sewer Pipe, Hamilton 11,	60
Sewer Pipes and Specials, Moose Jaw 18,	60
Sewers, Vancouver 21,	62
Sewers, Vernon, B. C. 13,	62
Sewer, Vitrified Brick, Point Grey, B. C. 5,	60
Sewer and Water Mains, Moose Jaw 17,	64
Sewers, Westmount, Que. 19,	64
Seymour Creek Extensions 2,	60
Seymour Creek Waterworks Supplies 7,	60
Shops, C.P.R., Calgary 9,	60
Sidewalks, etc., Moncton, N.B. ..20,	60
Sidewalks, North Battleford 18,	62
Sidewalks, Sewers, Pipes, etc., Lethbridge 17,	62
Sidewalks, Vernon, B. C. 23,	70
Sooke Lake Waterworks 1,	59
Steam Engine, North Battleford, 22,	64
Steamer 13,	60
Steam Turbine, Calgary 15,	62
Steel Pipe, Moose Jaw 4,	60
Steel Water-pipe, Moose Jaw 18,	60
Street Paving, Lethbridge 2,	59
Subway, C. N. R., Saskatoon 10,	60

The Canadian Engineer

An Engineering Weekly

CONCRETE FACTORIES.

The varied uses of cement in industrial constructions grow apace with increased manufacture and decreased cost of the staple. The American Association of Portland Cement Manufacturers have gathered data together which shows the possibility of all steel and cement construction as applied to factories, warehouses and other buildings necessitating commodious floor space.

To an engineer about to assume the responsibility of the erection of an industrial structure, the employment of concrete would have to be considered in the specific case.

Concrete Motor Car Factory.

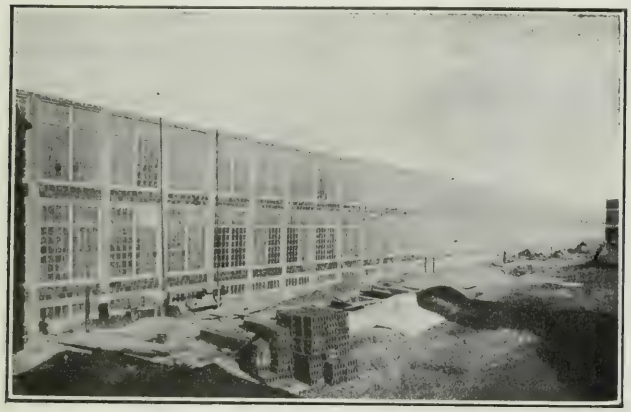
It is very interesting, however, to examine the points brought forward by the cement association mentioned above.

From an industrial point of view, the advantages of a reinforced concrete building are its fireproofness, waterproofness, verminproofness, sanitary qualities, maximum light available, load-carrying capacity, vibration, resistance, permanence, adapability, speed of construction, low heating charge, low initial cost and its fire protection value.

Compared to any other fireproof type of building, reinforced concrete for industrial buildings is the lowest in initial cost. It is generally found that on a four or more storey factory or warehouse, with live loads of 150 pounds or more, reinforced concrete buildings cost from 10 per cent. to 20 per cent. or even 25 per cent. less than a similar design in structural steel properly fireproofed. Compared to non-fireproof buildings, concrete will vary from equal cost on large propositions to possibly 30 per cent. greater cost on medium sized propositions, and sometimes 40 per cent. and 50 per cent. on the smaller buildings when the comparison is made with the cheapest form of brick and frame construction. These percentages will, of course, vary for different sections of the country, but are in a measure fair statements for general usage. These costs are exclusive of building equipment such as plumbing, heating, lighting, elevators and sprinklers, as these items run about the same on any type of building. What these costs really mean is that a prospective builder can obtain a fireproof structure, if he uses reinforced concrete, at a cost little in excess of the non-fireproof or at best slow-burning form of construction. Before the introduction of reinforced concrete construction the only fireproof form of building was structural steel fireprofed.

A reinforced concrete building gives very nearly full protection from fire. Even though the building is in a conflagration district, if it is properly protected with wire glass windows, fire doors, etc., it will, as far as it is pos-

ible to judge, come through a conflagration uninjured. If he fire is a local one, it would be confined to the floor or oom where it started. The underwriters' records of the Jnited States show that there are forty fires causing loss in xcess of $25,000 per fire every week among industrial build-ngs in that country, and that the annual per capita loss for he United States is something in excess of $2.30 as com-ared to an average loss per capita of seven European cities f 30 cents. The cost of a reinforced concrete fireproof uilding under most conditions would not exceed a non-reproof type of building by over 10 or 15 per cent.



Concrete Cotton Factory.

The most serious damage to the contents of a building fter a fire is due to water. To this condition, concrete uildings owe much of their popularity at the present time. concrete floor is a monolith, and water from sprinklers or ose will remain on the floor where it falls and does not un down through several storeys as in the case of ordinary ypes of construction. The best practice of the day in the esign of concrete industrial buildings provides a small urb, generally not over three inches high, at all stair and evator wells, lowerator shafts, and other openings through oors, so that there is no possibility of water from a flooded oor flowing into the lower story. To make this certain scup-ers are usually placed in the walls. Furthermore, the aterproofness of a reinforced concrete building is of great ervice where industries using wet processes have to be oused, or where industries requiring frequent cleaning of ooms or floors are the tenants. A concrete building may be ashed down with a hose and no damage results. The new ork Board of Fire Underwriters are accepting concrete oors with a granolithic finish placed on two inches of rich nder concrete as waterproof and give the same rating as her types of floors which have three- or five-ply tar and lt waterproofing laid between the structural part of the oor and the floor surface.

A building where there is no dry rot, no dampness, no ermin, and where cement, which is a lime product and aturally sanitary, is the chief material of construction, is ery nearly ideal from a hygienic viewpoint.

The sanitary qualities of a building and efficiency of em-oyees vary almost directly with the amount of light obtain-ble in a building. Concrete factories are noted for the ease ith which abundant light is obtainable in them. The rdinary brick and mill construction and brick or frame uilding has rarely over 20 or 30 per cent. of its wall area windows, whereas the normal window area for a reinforced oncrete factory is 50 per cent. and in many cases runs as igh as 85 per cent.

Owners of concrete buildings have shown that they can crease the efficiency of their employees 5 to 10 per cent., and often even more, by having well-lighted, clean rooms. Concrete buildings possess an advantage over most other types of construction along this same line, not merely from the extra amount of light available, but also from the extra ventilation which the large window area gives. This is of importance, especially through the summer months.

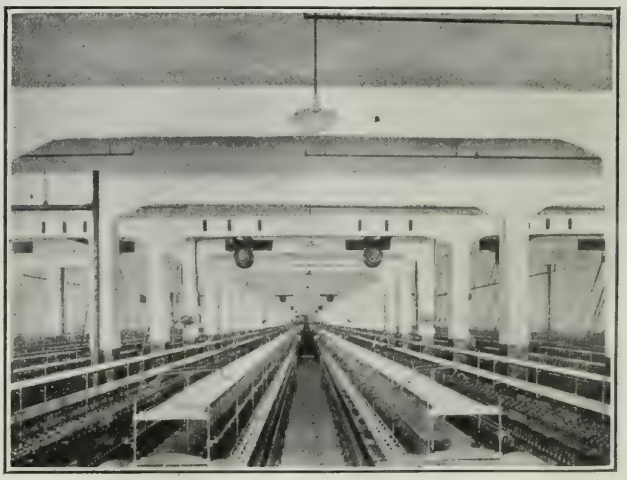
The great window area which is obtainable in reinforced concrete factories reduces the lighting charges materially and in many cases makes artificial light almost unnecessary. Light courts or very narrow buildings often become unnecessary when reinforced concrete is used. By allowing the windows to extend to the ceiling line the light from these windows will reach 40 or 50 feet into the building in an efficient manner.

Reinforced concrete increases in strength with age. There are many tests of cement and concrete briquets and cubes which demonstrate beyond controversy the increase in strength with time.

Poor workmanship and unusual conditions have sometimes occurred on buildings, but the material after once in position has always responded without a single sign of weakness. Concrete floors which have been designed for a strength of 200 pounds have been known to carry 500 and 600 pounds, and floors which have been designed for loads of 600 pounds are carrying 1,200 and 1,500 without incurring the slightest defection.

Concrete floors have been built to carry as high as 5,000 pounds per square foot, and it may be safely stated that a concrete building designed for the same loading as is used in any other type of building is by far the stronger of the two.

An interesting commentary on the strength of concrete buildings is found in the latest practice in design which is becoming more and more prevalent. Advantage is taken of the increase in strength with time of a concrete building. If



Interior of Concrete Cotton Factory.

an owner desires a building to be four stories high, but to be so built as to later carry a fifth story, the columns are designed to carry the loads which will be brought on them if the building were to be ultimately only four stories high. At the end of a year or two these columns will have increased in strength to such an extent that a fifth story can be safely added, and the resulting loads on the columns will not produce stresses above the factor of safety used in the original design.

A reinforced concrete factory or warehouse, properly designed and erected, may be said to be the most rigid building which can be put up. The reason for this is almost self-evident. The floors and columns of a concrete building are

cast or poured at one time, and become a homogeneous mass, that might have been carved out of a solid block of stone. Rapidly moving machines, heavy embossing presses, electric motors, milling machines, high velocity engines, and, in fact, any heavy equipment can be installed in a reinforced concrete building and run at highest speed and in the story below its presence is scarcely discernible. It has been found that machinery can be operated at higher speeds and at greater efficiency in concrete buildings, owing to the rigidity of these buildings, than in any other type of construction. While it is true that there are some concrete buildings where vibration is noticeable, the conditions in these buildings are such as to create vibration in any kind of a structure, and the amount existing in the concrete building is certainly less than would otherwise be obtained. Concrete was early selected for the housing of the publishing and printing industry because it permitted the placing of large presses in upper floors of the building, without danger to the safety of the structure.

One type of vibration which concerns many manufacturers is due to a very slight lack of balance in parts rotating at high speed. This is in distinction to the vibration that might be caused by machinery of a heavier type due possibly to the reciprocation of heavy weights or to the shock, as in punch press work and the like, or vibration of a machine due to "chatter." It has been found that in reinforced concrete factories the usual difficulty of installing machinery so that high frequency vibration would not in a short time loosen the fastenings, as well as cause loss of adjustment to the machines, has been almost enirely overcome. It has further been found that machines standing high from the floor and subject to more or less horizontal shock can be held rigidly in place. This is a condition which in mill construction, at least, is almost impossible to bring about.

The effect of this property on the tenant of a factory is great. If machinery or shafting can be set or bolted to a

Iron Company Concrete Core Room and Carpenter Shop.

concrete floor, or hung from the ceiling without the possibility of its getting out of line or level, the repairs to the machines in new bearings, the amount of attendance, the quantity of oil used, and the general up-keep are greatly reduced. Many owners of concrete industrial buildings have found that they save considerable money by having their machinery in this type of building, as compared with any other type of structure.

In many light manufacturing buildings consideration has to be given to the position of heavy stock piles or machines, it being necessary either to place extra heavy loads over a beam or girder or make provision to distribute the load. In concrete buildings this rarely occurs. Furthermore, in the ordinary type of building the movement of an unusually heavy load across the floor often disturbs the shafting or other machinery hung from the ceiling below. In concrete construction the foreman of a department seldom has to think of such a contingency.

The speed of construction of reinforced concrete buildings has been misrepresented many times, and a number of buildings have been designed in mill construction because their owners were afraid that if they elected to use reinforced concrete there would be such delays as to make the use of concrete prohibitive. There have been, it is true, many concrete buildings put up where the time of completion has dragged along to an unreasonable extent, and the owners

Concrete Meter Factory.

have had every reason for complaint. Most of such cases, however, have been due chiefly to inexperience on the part of the contractor or unreasonable requirements on the part of the engineer or owner.

With an experienced contractor, and ordinarily fair working conditions, reinforced concrete factories or warehouses can be, and in innumerable instances have been, erected in a time which compares favorably with any other type of construction. Speed in concrete work means essentially a well organized and experienced contractor.

A few instances of quick concrete construction would include:—

The Mason Warehouse at 134 Johnson Street, Brooklyn, New York, is 40 by 80 feet in plan, seven stories and basement in height. After the completion of the excavation but forty-eight working days were used to the completion of the roof, and the building was turned over ready for occupancy, including plumbing, heating, lighting, and elevators, in three months and one-half after the signing of the contract.

The Rogers-Pyatt shellac factory at 34 Fletcher Street, New York City, is ten stories and basement in height, and about 60 by 70 feet in plan. After the completion of the foundations, which were special, forty-seven working days were consumed to the concreting of the roof and three and one-half months elapsed from the signing of the contract to the delivery of the building ready for occupancy.

The Robert Gair warehouse, on Front and Washington Streets, Brooklyn, New York, a twelve-story building with twenty thousand square feet to the floor, was constructed, twelve floors in eleven weeks, and the building turned over ready for occupancy in seven months after the signing of the contract.

It is the general practice of reputable concrete construction companies to carry their buildings up at the rate of a story per week after the first floor is concreted. A seven-story building, about ten thousand square feet to a floor, can be guaranteed completed in from four to five months after the contract is signed.

An investigation of over 200 reinforced concrete industrial buildings showed that in none of them was any damp-

oofing placed. All the buildings have given perfect satis- tion on this score. Concrete walls 8 inches in thickness, operly built, are practically impervious to weather. In ses where the temperatures are high there may be a ten- ncy towards condensation, but this would be true with y character of wall which was not furred to provide a dead space. The prevalence of the idea that concrete build-

Interior of Concrete Embossing Factory.

rs are damp probably is founded on the old-fashioned con- te cellar or rubble wall cellar, which was under a static id of water, and, therefore, very liable to dampness. stering may be applied direct to the inside of concrete lls 8 inches or more in thickness without danger of the stering coming off. The fact that piano factories, which uire about as dry a building as any other type of indus- , have been built of reinforced concrete most satisfactorily, nishes an interesting example of the lack of dampness in crete buildings.

In exterior appearance a concrete building, as illustrat- will compare in appearance favorably with any other type building when designed accordingly. The old prejudice the part of the general public against concrete from the hetic point of view is due to the psychological fact that at the eye has not seen the brain cannot conceive. The n in the street has come to know brick, stone, and older es of exterior construction and to accept them for what y are and to distinguish between good work and bad work the various classes. Until there has been enough con- te work for the public to become used to it and to learn distinguish between good concrete and bad concrete, there bound to be somewhat of a feeling against it. Admitting s condition, it is not necessary for the prospective builder turn down concrete as a structural material. Rather, he uld use brick, stone or whatever material suits his whim a veneer or as bearing walls and let the structural part his building be of concrete. In other words, reinforced crete may be used for the frame of a building in the same y that structural steel is used for skyscrapers the country r.

Difficulty of Installing Mechanical Equipment.—Perhaps most common prejudice against reinforced concrete for ustrial buildings is the supposed difficulty of installing in satisfactory and economical manner, piping, machinery, tors, and other merhanical equipment. While it is un- ubtedly true that it is harder to cut into a concrete ceiling beam than into wood or brick, the extra amount of labor d time involved is much less than those inexperienced in ch work would imagine. As a matter of fact, in the ma- ty of industrial concrete buildings erected to-day pro- vision is made during the course of construction so that equipment of every character can be readily installed with- out any cutting whatsoever. This is generally accomplished by leaving holes sufficiently large to take a ¾-inch bolt through the beams and girders just underneath the floor slab. These holes are spaced generally from 24 to 36 inches on centres. By use of hanger bolts or sockets, any kind of equipment can be supported rigidly from the concrete ceil- ings. In construction where there are no beams or girders, cast-iron spool sockets are set at regular intervals in the ceiling. These sockets are tapped for bolts of any size and provide a very simple means of attaching machinery. In fact, these cast-iron spool sockets are not infrequently set in the bottoms of beams or girders or in the floor slabs be- tween same. Shafting is ordinarily supported on 3-inch by 6-inch wooden stringers which are bolted to the concrete ceil- ing. As previously noted, machinery or shafting thus attach- ed to concrete construction remains rigidly in place without any of it getting out of line or level which is so common in other types of buildings.

The installing of plumbing, heating, and sprinkler pipes is handled usually in a different manner from other me- chanical equipment, in that it is customary to write contracts and specifications for concrete buildings with the provision that the sub-contractors for these different classes of work have to set sleeves or indicate where they wish holes left in the concrete construction before the floors or walls are con- creted. It is then up to the concrete contractor to meet their requirements.

Most machinery is set on the floors and not supported from the ceiling. Two problems are then presented: First, where the machinery is sufficiently heavy so that it may rest

Interior of Concrete Bakery.

without bolting upon the concrete floors or be grouted in place; and, second, light machines which have to be secured to the floors. The first class of work is obviously simple and needs but little attention except to note that concrete floors lend themselves very readily to grouting, and, in their stiffness, prevent any tendency towards movement of ma- chines. The second class of machinery is provided for gen- erally in two ways: First, by drilling holes from two inches to three inches deep in the concrete floor and either driving wooden plugs into these holes and then attaching the machine by use of ordinary bolts or screws or by setting expansion bolts in the holes direct and hold- ing them in place with lead or sulphur. The drill- ing of these holes may, in the eyes of the uninitiat- ed, form a problem. As a matter of fact, it has been found in actual practice that these holes can be tapped in the con-

crete floors very easily. The second class of machinery, which the drilling of the holes and the setting of anchor or expansion bolts does not take care of, consists of very light machines or machines which have to be moved frequently. Here it is generally good practice to install over the concrete structural slab a wooden floor to which the machines may be bolted as in an ordinary building. Most reputable concrete engineers and contractors, although very enthusiastic over their form of construction, are not blind to certain conditions which something other than concrete had best be specified.

If provision is made beforehand, such as above noted, equipment can satisfactorily be installed in concrete buildings. Assuming that no provision has been made during the construction of the building for attaching any mechanical equipment. The general practice among the occupants of concrete buildings is to use expansion bolts set in holes tapped in the concrete. In a large building where there is a great amount of such work to be done or where changes are constantly occurring, the most economical way to meet this problem is to purchase a small portable air compressor, generally operated by electricity, and use a pneumatic drill. The cost of such a compressor is low and the economies which it effects soon more than equal the initial outlay. But even in a building where such a machine is not available, it has been found that holes can be cut into concrete at an almost negligible cost. The results of an investigation of some fifty concrete buildings in the Metropolitan district of New York City about a year ago showed that the mechanical engineers or factory superintendents, after the first few weeks of occupancy of their new buildings, got to regard cutting holes in concrete beams, for the setting of expansion bolts or other devices, about as they did cutting into wooden beams. This may at first seem to apply wholly to machinery or shafting. Alterations in piping layouts require, of course, cutting holes through floors or walls or partitions. This is somewhat more difficult than the tapping of expansion bolt holes, but if a little discretion is exercised it will be found that alterations of this kind are not really burdensome. It is sometimes objected that additions may be necessary to buildings which require removal of walls, or departments may have to be moved from one part of the building to another, which may require removal of partitions. In cases such as this concrete should not be used for walls or partitions. Exterior walls should be built of a material which can be readily removed. Partitions should be made of concrete blocks or hollow tile or lath and plaster, which brings this problem to the same footing as in other types of construction.

Coal pockets above 3,000-ton capacity cost from $6.00 to $7.50 per ton. Reinforced concrete stand pipes above the foundations cost from 2½ to 3 cents per gallon.

It is difficult to give a comparative insurance rate on industrial buildings in Canada owing to each one being rated specifically, local circumstances having entire control over the schedule. A concrete building reinforced with steel, and provided with metal window sashes supporting wire glass, and containing little or no interior woodwork, is rated by fire underwriters as "fireproof." The insurance rate on such a building in Ontario runs from 0.20 cent per $100.00 per twelve months upwards.

The estimated approximate unit costs of reinforced concrete buildings of various types are shown in the table below:—

Type of building. Dimensions.	Live lead. per sq. ft.	Cost above foundation. sq. ft.	Cost above foundation. cu. ft.	Cost includ'g foundation, sq. ft.	Cost includ'g foundation, cu. ft.
Machine shop, 120x50′, 4 stories	150	$1.05	$0.08	$1.17	$0.09
Machine shop, 220x100′, 1 story, sawtooth skylights		1.65	0.09	1.75	0.10
Cartridge factory, 223x56′, 2 stories	300	1.40	0.09	1.55	0.10
Cotton mill, 550x129′, 2 stories	75	0.99	0.07	1.06	0.075
Weave shed, 341x231′, 1 story, sawtooth skylights	125	1.66	0.064	1.79	0.07
Power-house, 90x62′,		2.53	0.115	2.67	0.12
Storehouse, 181x56′, 4 stories	150	1.08	0.065	1.15	0.07
Storehouse, 256x100′, 12 stories	150	0.90	0.09	0.98	0.105
Storehouse, 223x56′, 2 stories	300 and 1,000	1.20	0.08	1.35	0.09

LIGHTNING RODS.

In arranging aerial and ground connections in a system of lightning rods, the different rods are connected together on the roofs of the house. The rods situated on the gables, and on this account more exposed to the action of lightning, are always each provided with a separate conductor, one conductor to every two rods being sufficient in the case of those lower down. A conductor consists either of a copper wire 8 to 10 millimeters thick, or of copper wire rope containing seven wires 3.3 millimeters each in diameter. Only electrolytically pure copper should be used. Galvanized-iron wire cable, 15 millimeters thick, composed of twelve single wires 3.3 millimeters in diameter, is also employed. Large metallic bodies in the interior of the building, such as iron girders, iron pillars, rain, gas, and water pipes, metal roofs, etc., should be brought into good conducting connection with the conducting rods by screws and soldering. The object of the ground connection is to conduct the lightning to the earth with the least possible resistance. For this purpose copper plates 2 millimeters thick and from 0.5 to 1 square meter in area are generally employed. If there are more than two ground plates to one conductor, the size of the plates can be reduced to 33 by 100 centimeters. Galvanized-iron plates 1 square meter in area and 5 millimeters thick, iron rails, water mains (when allowed by law) can also be used for ground connection. The plates should be fixed in underground water, and far enough to remain covered when the water is at its lowest. If there is no ground water available, the electrode should be fixed in the moistest soil possible, e.g., in the neighborhood of rain spouts, kitchen drains, etc. In this case the surface of the electrodes must be doubled. Instead of solid ground plates, copper or iron wire netting may be used, but in selecting the size, care must be taken that they present the same conducting surface as the solid plates, i.e., one square meter. If the ground plate has to be placed in a well from which drinking water is taken, a galvanized-iron plate or galvanized-iron wire rope must be used, or the copper plate and connecting wires well tinned, on account of the poisonous character of the salts formed on the copper conductors.

COST OF GARBAGE REDUCTION.

The engineer in charge of the design and construction the garbage reduction plant built for the city of Columbus, hio, has just issued his report for the first year of opera-n. An abstract of the report is published hereafter:

A review of the history of the plant and a brief descrip-n of it is given, which states, among other things, that e city advertised early in 1908 for bids for the construction a reduction plant to be built in accordance with specifica-ns issued by the city, but no bids were received. The ecifications were at once revised and two bids were receiv-, but both rejected, because the lowest, $230,000, was con-dered too high. The Board of Public Service then decided at better results could be obtained by employing an en-neer to design and construct the plant so they could award ntracts on separate parts of the work, and Mr. Osborn was ployed for this work in July, 1908.

A reduction plant was designed with a capacity of dis-sing of 80 tons of garbage in 12 hours; this capacity be-g considered sufficient to take care of the future growth of e city for a number of years and at the same time provide any emergency in case of breakdown. Contracts for chinery were awarded in November, 1908, and this and e buildings were nearly completed by the latter part of 09, when winter shut down the work. The plant was com-eted and placed in operation on July 20 of the following ar and has been in continuous operation ever since.

At the same time the plant was being constructed, col-tion equipment and various buildings were being provid-

On a six-acre plot in a comparatively central location re built a garbage loading station, garbage collection ble, railroad sidings, dog pound, night soil station, street pair yards, wagon sheds and blacksmith and repair shop; ile work is now under way for the erection of a stable for e street cleaning department.

The dog pound consists of a small one-story frame ilding with an office in front and stalls for keeping dogs til released or otherwise disposed of. The nightsoil tion consists of a small one-story brick building contain-g a concrete basin in which the wagon tanks discharge eir contents, which is then diluted with water and flushed o the sewer. The stable is a two-story building 60 feet de by 200 feet long. Stalls are arranged in rows across e building, with a ten-foot passage aisle at the rear and a ır-foot feeding aisle at the front. A centre aisle 8 feet de runs the entire length of the building. The stable has capacity of 160 horses, and the ground room also contains rness rooms and the office of the stableman. The second or is used for storage of feed and also contains the office the superintendent of collection and a locker and bathroom the men.

The garbage loading station consists of a two-story brick ilding 40 feet wide by 90 feet long, with railway tracks tending through it. The wagons are driven up an incline iveway onto the second or loading floor which is about 15 et above the railway track. The wagon is backed up to bumping rail and the front end of the wagon body elevated th power hoist, thus discharging the garbage into the car low. The building houses two cars at one time when the rge double track doors are closed, so that all work of load-g is done inside the building. Four garbage cars were rchased for transporting the garbage to the disposal plant. ese cars were especially made, having a steel semi-circular dy set on trunnions so that they can be turned to dis-arge the load. The cars have a capacity of 80,000 pounds 1,400 cubic feet of garbage.

Thirty-four garbage wagons were purchased for use in collection. These wagons were built according to the city's specifications and consist of rectangular steel bodies mount-ed on heavy running gears. The wagons are provided with spring seat, and canvas covering put on in sections. The sectional canvas cover makes it necessary to uncover only a part of the wagon at a time and at the same time does away with the noise caused by metal covers. The wagons have a capacity of 2½ cubic yards and the net weight of the loads varies from 1½ to 2 tons.

The loading station and other buildings described above are placed at a comparatively central point in the city, on the Scioto River. The reduction plant is located about 1½ miles south of the city limits, also on the bank of the river. The plant consists of four buildings—the green garbage or unloading building, the main or reduction building, the office and a small stable. A car of garbage, when delivered at the plant, is weighed on railway track scales and then run into the green garbage building on a railway siding which extends through it. The body of the car is then turned on trunnions by means of power hoists and the contents of the car discharged onto the floor below. Here the free water is drained off through a gutter covered with perforated plates which extends the full length of the building. The water so flowing off is drained into a catch basin from which it is discharged into grease separating tanks. The garbage is sorted and shoveled into a 24-inch scraper conveyer which extends the full length of the green garbage building.

Connecting the green garbage building with the main building is an inclined truss which carries the conveyer to the top of the latter building, where it discharges the garbage through swivel spouts directly into the digestors. When the garbage has been cooked in the digestors it is discharged through a large valve into a receiving hopper and from this to a roller press. The vapors which arise from the mass when dropped into the hopper are conducted to a condenser which in turn is connected to a vapor-tight steel hot well. The time required in cooking varies with the quality of garbage, but averages from 6 to 8 hours with the steam at from 60 to 70 pounds gauge pressure as it enters the digestor.

After passing through the presses the compressed material is carried to the drying department, where it is fed into a revolving cylindrical dryer. After being thus dried the material is passed through a revolving screen and the screened tankage is placed in vacuum mixing driers, together with the concentrated syrup from the evaporator. The dry fibrous material acts as a filler and enables the moisture in the syrup to be driven off. The addition of the syrup to the fibrous tankage provides a higher grade of tankage from a mechanical and fertilizing standpoint. When this mixture has been dried it is conveyed by a spiral conveyer and an elevator to the third floor where it is stored until shipment.

The water and grease from the press flow through a conduit to the grease separating room. The grease drained off from the separating tanks is heated in the treating tanks in order to separate out the impurities, and is then pumped into storage tanks ready for shipment.

The tank water drawn off from the grease separators is evaporated so as to recover the five to seven per cent. of solids in solution. An evaporator is used consisting of three pans, capable of concentrating 1,500 gallons of tank water per hour from 7 degrees Be. to 22 degrees Be., using exhaust steam at five pounds pressure and a vacuum of 25 inches on the third pan. The concentrated syrup is drawn off by a magma pump and discharged into a storage tank, to be added to the tankage as previously described. The feed pump to the evaporator is provided with a neutralizing gear and connected to a tank containing a neutralizing solution; thus

securing the mixture with the tank water of the amount of solution required to neutralize the acid so as to prevent its attacking the metal.

The city now has under construction a percolating plant to be used in extracting grease from the dry tankage, as only about one-half of the available grease is recovered by means of the press. The percolating plant will consist of an extractor, vaporizers, condensers and storage tanks.

The electric current for both lighting and power is furnished by the municipal lighting plant at 1½ cts. per kw.h. An independent motor is connected with each power-driven unit and operated with 440-volt, 60-cycle, two-phase current. The boiler plant consists of three horizontal tubular boilers 78 inches in diameter by 20 feet long. Two of the boilers are in regular service and the third is in reserve.

The cost of the collection equipment and of the reduction plant was as follows:

Collection Department.

Loading Station site	$10,136.40	
Loading Station	14,101.64	
Collection Stable	41,796.55	
Trestle and driveway	2,153.10	
Grading, fill, electric wiring	2,379.54	
Garbage cars	7,564.00	
Garbage wagons	7,151.10	
Railway siding	3,161.60	
		$ 88,443.93

Reduction Plant.

Levee	$ 9,711.72	
Buildings, grading, etc.	81,267.05	
Reduction machinery	59,866.00	
Power equipment	21,356.70	
Railway tracks	3,342.80	
Conveying machinery	9,316.22	
Electric wiring	3,670.99	
Non-conducting covering	1,010.75	
		$189,542.23

Miscellaneous.

Office and advertising	$ 1,401.18	
Engineering	16,143.48	
		$ 17,544.66
Total		$295,530.82

As during the first six months of operation, that is the last six months of the year 1910, the works were new and the men unacquainted with operating them, Mr. Osborn has taken the first six months of 1911 as more representative of what results can be obtained. During this period accurate records were kept of the operation and the cost computed for each part of the operation. During the first half of 1911 the amounts of garbage disposed of each month were as follows:

January	1,063.08 tons
February	977.64 tons
March	1,114.75 tons
April	1,175.22 tons
May	1,364.05 tons
June	1,371.39 tons
Total	7,066.13 tons

The above includes 94 dead horses and 9 cows.

The plant was operated 153 days, and the average tonnage per day was 45.59.

As the plant has a capacity of 160 tons of garbage in 24 hours, the disposing of 45.59 tons per day was done ordinarily during one eight hour shift. During the remaining shift only such work was done as required more than eight hours. If the tonnage of garbage was sufficient to operate the plant at full capacity the cost per ton would be decreased, as the same number of men are required to operate the machinery irrespective of the tankage to be disposed of.

The receipts of the works from the products were as follows:—

206.48 tons of grease	$21,413.92
1,132.03 tons of tankage	10,338.42
62 hides	253.90
Miscellaneous	1.50
Total	$32,007.74

In addition to this there was on hand June 30, 1911:

43 tons of grease @ $100.00	$4,300.00
156.34 tons tankage @ $10.00	1,563.40
34 hides @ $4.00	136.00
Total	$5,999.40

The inventory of January 1, 1911, was:

68.44 tons grease @ $108.00	$7,391.52
100 tons tankage @ $10.00	1,000.00
Total	$8,391.52

This makes the net receipts from by-products recovered from 7,066.13 tons of garbage to be $29,615.62.

Each carload was analyzed for determining both the fertilizing elements (on which the price per ton is based) and also the percentage of grease left in the material, these analyses showing this percentage of grease to be approximately ten. It is believed that if the percolating plant which is now under construction had been in operation, a recovery of 8 per cent. of grease would have been made, which would have amounted to 95 tons, valued at $9,500. The operation of the percolating plant would have required an additional expense of $2,000, leaving a net revenue from this plant of $7,500. The total cost for the collection of garbage for the first six months of 1911 amounted to $17,794.99; so that, with the percolating plant operating, the receipts from garbage would have been $4,313.44 over and above the cost of collection and disposal.

The total expenditures for the six months were as follows:—

Supervision and payrolls	$9,724.03	
Coal	2,349.75	
Electric power	843.90	
Repairs and renewals	849.24	
Supplies	548.13	
Office expense	185.78	
Miscellaneous	191.84	
Unpaid bills July 1st, 1911	839.52	
		$15,532.19

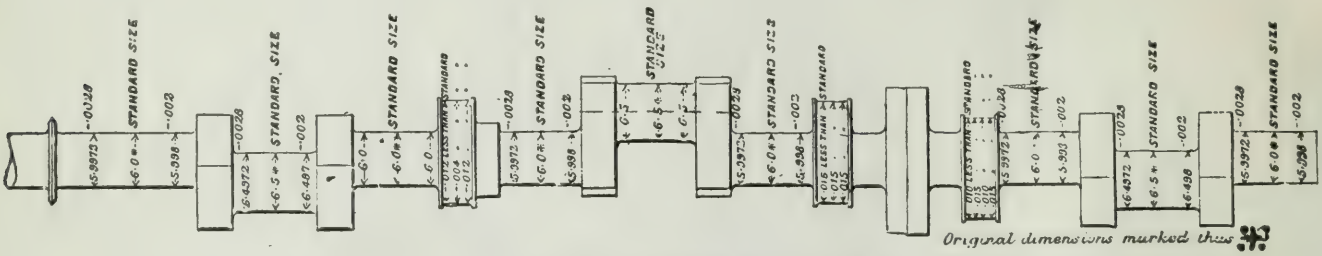
Inventory coal and supplies, July 1, 1911:

250 tons coal @ $1.30	$ 325.00	
Pipe, fittings, supplies, etc.	200.00	
		525.00
Total net cost of disposal		$15,007.19

This leaves a difference between receipts and expenditures of $14,608.43. As 7,066.13 tons of garbage were disposed of, this shows a net revenue per ton of garbage of $4.19, a net cost per ton for disposal of $2.12 and a profit per ton of $2.07.

THE WEAR OF MACHINERY.

How nearly forced lubrication can produce and maintain the ideal condition of confining all the wear to the oil is shown by the engraving on this page, which records the original and present dimensions of a three-throw crank-shaft, which had been at work for seven years. We are indebted for this information to A. L. Mieville, resident engineer for Canada, of Messrs. W. H. Allen, Son & Company, Limited, of Bedford, England, who designed and built the engine, and which firm is represented in Canada by Chapman & Walker, Toronto. It was intended to develop not more than 200 horse-power, with an occasional overload; but for seven years it has run for 12 hours a day and 300 days a year at considerable overload, the rate of revolution being 300 per minute. After all this long and arduous work the wear in many places is not capable of being measured, and in all



Sketch of Shaft, Showing Original and Present Dimensions.

other parts is merely microscopic, it being a noteworthy feature that all the bearings remained cylindrical.

The crank-pins are all 6.5 in. in diameter, and all journals are perfectly round, and in all three cases this diameter has suffered no diminution in the centre. The ends, however, in two cases have been reduced a little, the smallest figure being 6.4972, a wear of $\frac{28}{10000}$ in. The bearings were originally 6 in. in diameter, and in one case there is no measurable diminution. In all cases the bearings have kept their original dimensions in the centre, there being in most of them a slight wear towards the ends, the smallest diameter in the six bearings being 5.9972 in., a reduction of $\frac{28}{10000}$ in. The eccentric sheaves, with their rapid surface motion, have suffered more, but in these cases the largest reduction is $\frac{15}{1000}$ in.

One lesson taught by these measurements is that lubrication only fulfils its ideal purpose of absolutely preventing wear when it is perfect. The oil is led to the centre of the bearings, and at that point it absolutely keeps the metals apart. But towards the ends the film falls off slightly, with the result that there is some wear, although it is so small that it is of no account, being nowhere over $\frac{5}{1000}$ in.

Here we have a crank-shaft 13 ft. long, with three crank-pins and six bearings, and conforming so closely to its designed dimensions that instruments measuring to the ten-thousandth part of an inch cannot detect a difference at any part. And, thanks to the care and skill applied to the lubrication, many of these dimensions have suffered no change after seven years of hard and constant work. Such results can only be attained by the modern tools, coupled with splendid management and organization.

Over 19,000,000 square yards of bitulithic paving have been laid during the last decade in Canada and the United States.

LOCH LEVEN HYDRO-ELECTRIC INSTALLATION.

In the course of his paper before the Institution of Civil Engineers of Great Britain, on the Loch Leven Water Power Works, Mr. A. H. Roberts, M.I.C.E., said the Loch Leven Water Power Acts were obtained in 1901 and 1904, authorizing the construction of works to utilize the rainfall of the western slope of Rannoch Moor for power for industrial purposes. The scheme possesses a number of advantages, including large catchment-area, heavy rainfall and high head, all in proximity to the seaboard. The author refers to the usual waterworks practice of reckoning only upon the mean rainfall of the driest three consecutive years, and suggests that in power-schemes of this character it might often be possible to obtain a greater output of power with the same expenditure. This could be effected by installing extra units of power plant (turbines, etc.), making a reduction in the height (and therefore in the cost) of the storage dam, and arranging to work the extra power in wet seasons.

The catchment-area for the Loch Leven Works is the basin of the River Blackwater, and is 55 square miles in extent, lying between Lochs Treig, Ossian and Rannoch and Glen Coe. Rain-gauges established in 1905 and 1906 have given average readings of over 70 in. for Blackwater basin and 80 in. for Kinlochleven. No compensation-water had to be supplied, this feature greatly increasing the available power. The site of the reservoir is favorably contoured for storage purposes, and the full reservoir is about 7½ miles in length and ½ mile in breadth. Its greatest depth is 75 ft., and it impounds over 20,000 million gallons of water. The Blackwater dam is 3,112 ft. in length, with a maximum height of 86 ft., its top surface being 1,068 ft. above Ordnance datum. About half its length is formed as a waste-weir in six horizontal steps of 6 in. each. The foundation is of an exceptionally sound character; only a few feet of the surface beds had to be removed to obtain a satisfactory foundation. The plant and materials required for the construction were brought by sea to the wharf and carried thence to the dam, etc., by an overhead cableway and an overland railway of 3 ft. gauge, which latter included two rope inclines. The cableway was driven by a Pelton wheel at the foot of the Falls of Leven. The dam is built of large blocks of stone embedded in a matrix of ordinary concrete, with fine concrete facework. The bulk of the cement was of rotary-kiln manufacture, and exhibited certain characteristics, which are described. Cracks due to the contraction of the concrete appeared after the dam was built, traversing it vertically from top to bottom. Reference is made to the question of inserting contraction-joints in large dams. The valve-tower contains the six valves of the three draw-off pipes, the spindles being carried up to the valve-house above top water level. The draw-off pipes lead to the upper penstock-chamber, whence the water is delivered over a measuring-weir into the conduit.

Water is conveyed to the pipe-track by this conduit, which is 3½ miles in length; it is of square section, 8 ft. by 8 ft., and is laid to a general gradient of 1 in 1,000. The construction consists for the lower part of a channel excavated in the rock and lined with concrete; while the work above rock level is of concrete reinforced with expanded metal and round bars. Expansion joints are inserted in the walls at intervals of 64 ft. Contraction cracks, however, appeared midway between these joints until the conduit was brought into use, after which they closed up entirely. The arrangements for the maintenance of the natural surface drainage are described, and also the methods of shuttering and concreting the work. Along the route of the conduit and above the same lies a catchment-area of 3½ square miles, with a rainfall of about 75 in., the greater part of which is drained by three streams. These have been laid under contribution by collecting their water and turning it into the the conduit. A description is given of their intake works and of the automatic valves for throwing off superfluous water. Electrical transmitters and recorders indicate to the valve-keepers at the lower penstock-chamber the changes taking place in the contribution of the side streams, enabling them to take advantage of the extra water and reduce the draw-off from the reservoir, thus storing an equivalent quantity of water in the reservoir. The conduit discharges its water into the lower penstock-chamber of about 300,000 gallons capacity, where it is measured and delivered to the pipes as required.

From the penstock-chamber water is conveyed to the power-house in six welded steel pipes of 39 in. diameter. The track is 1¼ miles in length, and the fall of 935 ft. yields a normal static pressure of 406 lbs. per sq. in. Pipes are supported upon concrete pedestals, and at the bends there are heavy concrete anchorages to resist the thrusts of the water and pipes. The pipes are made from one plate welded longitudinally, and vary in thickness from 10 millimetres (0.394 in.) at the top of the hill to 22 millimetres (0.866 in.) at the foot. With the exception of flange-joints in special positions the whole line is jointed with a special "muff" joint, a form of spigot and socket with joint rings for securing the packing material. Expansion is thus accommodated at every joint. The pipes were brought to the site by an overland railway laid up the hill alongside the track, and were lifted into position by specially-adapted derrick-cranes. Water is distributed from the six main pipes to the various turbines by a system of pipes comprising two omnibus pipes and six feeders, all of 39 in. diameter. Each "bus" pipe with its three feeders forms one complete system, the two systems being at different levels to enable branches to cross. One branch from each bus pipe feeds each turbine. The main valves which control the supply of water to the distributing pipes are of ordinary sluice-valve type, but specially designed to meet the combination of large diameter and high pressure. They are hydraulically worked, and are fitted with operating gear and automatic closing appliance, together with a mechanical device for controlling the speed of closing. At the top of the pipe-track, immediately below the penstock-chamber, automatic cut-off valves have been installed, of the usual "butterfly" pattern, to stop the flow of water in the event of a burst occurring on the main pipe-lines. At the summit of a slight elevation in the main line air-valves have been fixed of a special design to allow large quantities of air to pass in or out, as required, when filling or emptying pipes. The tail race is of concrete, the channel leading to an outfall in the River Leven.

The company have constructed a wharf and a jetty, both of timber, in Loch Leven; and have dredged a channel through the Loch Leven Narrows. A domestic water supply has been installed for the village and factories of Kinloch-leven. It comprises a storage-reservoir with [illegible] in a neighboring valley, pipe-line, a service reservoir of reinforced concrete, and distributing mains. The dam at present is only carried up to half its ultimate height, but when completed will be 55 ft., and its length will be 440 ft. Contraction-joints are provided, and have proved efficient in preventing the occurrence of cracks.

The works have cost about $3,000,000, and are now the property of the British Aluminium Company. The construction was begun in August, 1905, and the factory commenced working in February, 1909. The engineers were Messrs. Thomas Meik & Sons, and Messrs. Kennedy & Jenkin in collaboration with Mr. W. Murray Morrison, the manager and technical adviser of the company. The principal contractors were Sir John Jackson, Ltd., and there were other subsidiary contracts. Mr. A. H. Roberts was resident engineer.

RETROGRESSION IN TENSILE STRENGTHS OF CEMENT.

At a meeting of the American Society of Civil Engineers, held in New York on November 15th, J. M. O'Hara, Assoc. M. Am. Soc. C.E., read a paper on the above subject. After taking up the specification for Portland cement adopted by the American Society for Testing Materials, which require no retrogression in strength between 7 and 28 days, the writer goes into an examination of the question as to whether or not retrogression is an indication of poor quality. Summarizing the principal ingredients of Portland cement and the action of the various chemical ingredients, he gives tables to show the action of American and European Portland cements at various periods between 7 days and 12 months, as well as the action of gypsum upon cement, and comes to the conclusion that the retrogression is probably due to calcium aluminates. He goes on to say: "The first strength is obtained from the calcium aluminates, as they hydrate quickly but the permanent strength is due to the calcium silicates, which are much slower in hydrating. The full tensile strength of the calcium aluminates is reached at one month, when they become more or less inert; at this age the calcium silicates are acting slowly, but are not strong enough to maintain the strain already reached by the calcium aluminates, hence retrogression takes place. The calcium silicates are constantly increasing in strength for an indefinite period, and gradually pick up the lost strength."

From the above he concludes that "if the action of the calcium silicates can be accelerated, so that the final strength is reached sooner, it is an advantage, and that this can be done in the case of American Portland cement by grinding the materials much finer and carrying a higher calcium silicate factor. The fine grinding accelerates the hydration of the calcium aluminates and silicates so that great strength is likely to occur at the 7-day period, and little or no gain, or even retrogression, at the 28-day period."

From this the writer proceeds to a table showing retrogression between the 7 and 28-day periods at intermediate dates at 10 and 20 days, and from this he argues that as this retrogression in many cases escapes detection by reason of the fact that the cement briquettes are only broken at 7 and 28 days, it is difficult to say that a cement giving these results is fit for use if one showing retrogression should be rejected.

The paper was discussed by a party of engineers who took the opposite side of the question, claiming that retrogression was an indication of defective manufacture and of inherent defects in the cement itself.

WIND PRESSURE AGAINST INCLINED ROOFS.

Experiments to determine intensity of wind pressure gainst inclined roofs were conducted during 1910 and 1911 y Mr. H. P. Boardman, of the faculty of the University of Nevada at Reno. He has compiled the results of his investigations in a paper presented on December 6 before the Western Society of Engineers, from which the following notes have been taken:

In these tests it was desired to approximate as closely s possible the conditions that exist in an ordinary building. To do this the model house as shown in diagram in Fig. 1 vas built. The house was 10 ft. long with hinged roof and o projecting eaves, and was open on the leeward side. hrinkage had developed some cracks in the walls, but an nemometer, held inside the house while the wind velocity vas considerable, showed very little motion and no definite

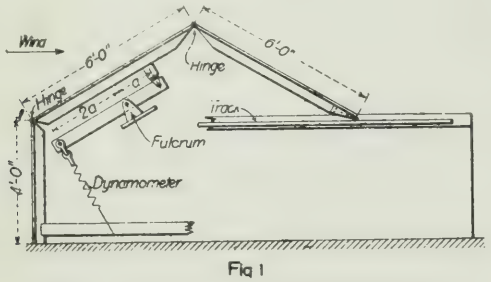


Fig. 1.—Diagram of Testing House.

irection to the air within. The two roof surfaces were overed with prepared waterproof roofing, and the gable nds closed with galvanized iron sheets, so hung as not to nterfere with adjusting the roof. The adjusting was accomplished as shown in Fig. 1 by means of small grooved heels supporting leeward roof and traveling on tracks as ndicated. Small canvas curtains weighted with iron rods t the lower edge covered the opening along the windward aves and ridge. The house was so mounted as to rotate hrough an arc of 60° in order to face the direction of wind. This was achieved by means of the centre post of the windward face acting as centre of rotation and three other posts oward the rear of the house with small wheels traveling on wooden track. The prevailing winds are from the west, nd the house was so placed as to command an unbroken vestern exposure to them.

The method of measuring the wind pressure against the oof was by means of a lever and spring dynamometer as hown on the diagram in Fig. 1. Standardizing the spring ynamometer gave a result of 144 lb. per inch of compresion of spring, on dynamometer scale. Assuming the pressure normal to the roof to be uniformly distributed over its o sq. ft. of area, the value per square foot is found by the ormula

$$Pn = (s—d) \times 144 \times 2 \times 4) / (60 \times 3)$$
$$= 6.4\ (s—d)$$

where

Pn = normal component of wind pressure in pounds per square foot against an inclined surface.

s = dynamometer reading in inches at time of wind load.

d = dynamometer reading in inches due to dead load alone. An anemometer was used for measuring velocity of wind.

The method of taking observations was as follows: An bserver stationed about 20 ft. to windward of the centre of he house held the anemometer at an elevation approximately equal to that of the centre of the roof surface. The inside observer watching the dynamometer signaled to the outside observer the time for starting the test, at the same time starting a stop watch; when dynamometer reading materially changed he signaled the outside man and stopped his watch. The outside observer had meanwhile automatically recorded the speed of the wind during the time interval of test, by means of a stop catch lever controlling the dial pointer of the anemometer without influencing the vanes. The estimated reading of the dynamometer, the duration of test and anemometer reading are then recorded.

Testing the anemometer used for possible inaccuracies it was found that the readings were too low for velocities below 12.8 ft. per second, and too high for those above that speed. The diagram, Fig 2, gives a graphical method of applying this correction and expresses the corrected velocities in miles per hour.

Individual velocities were first reduced by the formulas $V = 15\ v\ /22$ and $Pn = 6.4\ (s—d)$ to get values of V and Pn. The values for V were further corrected by means of the diagram in Fig. 2, and such values as fell within the range of 1 mile per hour, e.g., between V = 10 and V = 11. were averaged and plotted as abscissæ, with corresponding averages of Pn as ordinates. In some cases individual observations were plotted, and for higher velocities than about 18 miles per hour values of V showing a range of 2 miles an hour or even higher were averaged. It was observed that all high velocities came in gusts, lasting from a fraction of a second to 10 seconds, but few recorded tests were for less than 2 or 3 seconds.

A series of observations by Mr. Sears and Mr. Miller with velocities not exceeding 20 miles per hour, when plotted, showed, for small angles of slope, the points grouped closely along straight lines, the slope of the lines increasing as the angle of inclination increased. This, according to the author, would indicate less pressure at high velocities than expected. Mr. Boardman's personal observations covered a range of roof inclinations from 40 to 70 deg. with velocities as high as 50 miles per hour. Several observations were taken at 70 deg. as pressure at that inclination should closely approximate that against a vertical surface. Negative pressures were obtained at low inclinations and

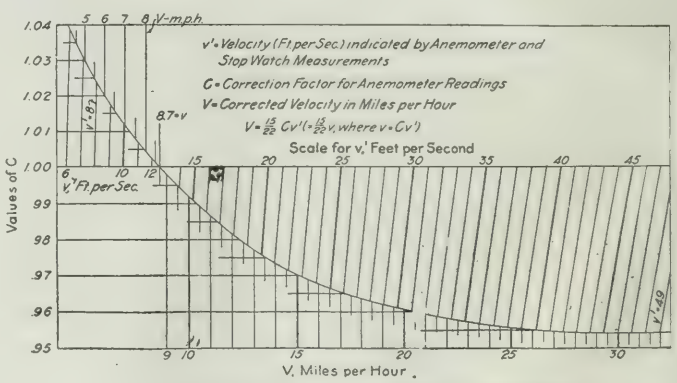

Fig 2.—Diagram of Anemometer Corrections.

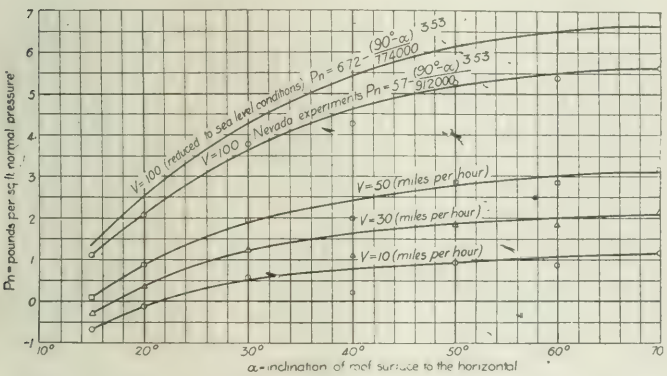
explained as follows: The wind deflected upward by the windward surface of the roof tends to draw with it, and thus rarefy, the air over the leeward surface, thus permitting the air within the building to press upward sufficiently to produce a negative pressure.

In his discussion of results Mr Boardman states: The results of tests by Mr. Sears and Mr. Miller seem to indicate a straight line formula, as the relation between Pn and V for each inclination of the roof, and this appears to be further justified by those of later tests, notably at inclinations of 40 deg. and 70 deg., the positions at which maximum velocity was recorded. Hence a series of empirical formulas

of the form Pn = a V + b were deduced from plotted observations at inclinations of 15 deg. and from 20 deg. to 70 deg. inclusive, at 10 deg. intervals, by the selection of average lines through the points plotted.

In order to determine the relation at any given velocity between Pn and the inclination of the roof surface, the values of Pn were computed for velocities of 10, 30, 50 and 100 miles per hour, and for inclinations ranging from 15 deg. to 70 deg. by the straight line formulas above mentioned and plotted in Fig. 3. In the selection of average lines, consideration was given to the resultant effect on curves of Fig. 3, as it appears there should be some regular law of increase in pressure with increase in angle of slope. It is to be noted that results of tests at 40-deg. slope when plotted would not give consistent points in Fig. 3, for the respective velocities, but fell below. No explanation is offered for this discrepancy, especially as results of the last tests made at 40 deg. inclination gave the most definite location of any, to the average straight line.

Since the pressure produced when V = 100 miles per hour is the commonly accepted maximum used in designing, a formula was computed on the basis of V = 100 to fit the points plotted in Fig. 3. In deriving this formula it was assumed from the appearance of the curves that the equation would be parabolic with its vertex on the vertical, through 90 deg. inclination. The general equation of the parabola



Pn = pounds per sq. ft. normal pressure
α = inclination of roof surface to the horizontal
V=100 (reduced to sea level conditions) Pn = 6.72 − (90°−α)^3.53 / 774000
V=100 at Nevada experiments Pn = 5.7 − (90°−α)^3.53 / 912000
V=50 (miles per hour)
V=30 (miles per hour)
V=10 (miles per hour)

Fig. 3.—Relation Between Wind Pressure and Slope of Roof.

with its origin at the vertex is $Xn = Ky$ where n is an unknown exponent, and K an unknown coefficient. Hence n log x = log y + log K or log y = n log x—log K, which are typical equations of the straight line.

Assuming a value of Pn as the vertex of the parabola and passing this curve through two other points, we have two values of x and two of y, with corresponding values of log x and log y. From these either graphically or analytically the constants n and log K may be obtained. By trial we select Pn = 5.7 as the vertex, and expressing x and y with reference to the origin at the vertex we have: x = (90 deg. α) and y = (5.7—Pn) where α = 9 α deg. For other points, assigning values to x of 40 deg. and 70 deg., and y = 0.5 and 3.6; we have α = 50 deg. and 20 deg. and Pn = 5.2 and 2.1. Passing a curve through these points and the vertex we obtain the following equation: $x^{3.53} = 912{,}000\ y$ or $(90 \text{ deg.} - \alpha)^{3.53} = 912{,}000\ (5.7 - Pn)$. Solving for Pn gives $Pn = (5.7 - y)$ or $Pn = 5.7 - (90 \text{ deg.} - \alpha)^{3.53} / 912{,}000$. This equation plotted is shown in Fig. 3. Since the atmospheric pressure at sea level is about 18 per cent. greater than at Reno it was assumed that wind pressure would be correspondingly greater and the equation $Pn = 6.72 - (90 \text{ deg.} - \alpha)^{3.53} / 774{,}000$ was derived on that basis. This equation, plotted, is shown in Fig. 3 as adapted for general use.

NOTES ON THE THEORY AND PRACTICE OF PERCOLATING FILTERS.*

By J. E. Farmer, F.C.I., Sewage Works Manager, Croydon.

Before anything new can be put into practical form, the mind must have been at work, and worked out certain details, also the expected results.

How and when the idea entered the mind of the first one to put into practice the percolating method of sewage purification I cannot say, as I have not seen any definite record of the event. It was probably brought about by the action of rain falling on porous soil, and the purification effected by this means. The means of imitating the dropping of rain for the spraying of the sewage on the surface of the filters I do not intend going into in this paper, as they are well known. The theory of the percolating method of filtration is that when a foul liquid is passed over a surface, such surface becomes coated with the purifying agent necessary for the purification expected. In practice it is known that by this means purification is effected, but the simple theory as mentioned is only a portion of that required to explain the whole working of a filter. By allowing the foul liquid to flow over a surface one obtains certain results: it is quite natural the mind would work on the questions of the cause and also on probable improvements.

One factor that comes to one's mind on considering the theory is that of surface area. It would be expected that if the area were increased, greater purification would be effected. This is proved by the greater purification given by a clinker filter than one of gravel, the grade and quantities being equal.

On comparing the surface area of a material of different sizes, it is seen that with the same mass the surface area can be increased considerably.

Taking a 1 ft. cube measure, which would hold one sphere of 1 ft. diameter, containing 904.78 cub. in., it would have a surface area of 452.39 sq. in., but the same measure would hold 1,728 spheres of 1 in. diameter, the total area being 5,428.6 sq. in., and the mass 904.78 cub. in., the same mass as the sphere of 1 ft. diameter, but with twelve times the surface area.

Another factor that must be taken into consideration is the size of the space left between one particle and another forming the body of the filter. If the size is too small, the friction is too great for the proper passage, in the downward direction, of the solid matter, also for the movement of the air.

Taking the same measure and spheres as above, the size of the spaces, with 1 ft. diameter sphere, would be 205.8 cub. in. each, and with 1 in. diameter 0.48 cub. in.

These calculations being made from mathematical figures, the results are more correct than those which can possibly be obtained in practice, but they are useful in giving an impetus to the mind to work out an ideal filter.

In the theory as mentioned the following conclusions are arrived at:—

(1) The smaller the particles comprising the filter, the greater the surface area.

(2) The smaller the particles comprising the filter, the smaller the individual space between the particles.

In my opinion, these two conclusions have a great bearing on the construction of a filter, when the work expected to be done is taken into consideration—namely, the

* Paper submitted at a meeting of the Association of Managers of Sewage Disposal Works at Croydon.

oxidation of the matter in suspension and the purification of the liquid. If the space between the individual particles is of such a fineness that the resistance to the passage of the solid matter is greater than the accumulation rate, choking is the result, also ponding of the surface.

The capacity of the interstices can be decreased, not only by using smaller material, assuming it is all one grade, but by mixing a small grade and a large together. This is apparent when the capacity of the interstices of any given grade of spheres is taken; for instance, 1-in. sphere—a cube foot would take 1,728 spheres of at least ⅜-in. diameter, and reduce the total capacity of the interstices from 832.22 to 775.5 cub. in., would but increase the surface area from 5,428.6 to 6,191.8 sq. in. The remaining interstices would still take a sphere of about 1/16 in. diameter, and still further increase the surface area, but with a lessened interstical capacity.

It is obvious that to increase the surface area by so mixing the grades, the resistance to the passage of the solid matter and air is increased.

A general conclusion of the foregoing is that the following are factors that must be taken into consideration before determining the grade of material to use:—

(1) Quality of the sewage liquid required to be treated.
(2) Quantity required to be treated on any given area.
(3) The degree of purification required.

In practice many materials are used, because of their cheapness or proved suitability. Clinker is the material mostly used, as in thickly-populated districts it is a by-product from the manufacture of products that have become necessitous with the rise of civilization. In other places gravel, waste from potteries, and so on, is cheaper, but cheapness should not altogether be taken as the main reason for the use of any particular material, as it may not have the properties required to produce the desired purification. Clinker has the advantage over many materials in having a large surface area for its mass, and so is very suitable, giving a greater degree of purification than smoother-surfaced material.

A material may be composed of such different-sized particles that when not graded the interstices may conform to that which is required for the filter; but care must be used, as the obtaining of a solid mass, as in the mixing of materials for concrete, is to be avoided, that which is to be kept in mind being maximum surface area with the maximum interstical volume. To obtain these maxima, clinker is generally used, and the filter built up in grades, the larger size at the bottom decreasing in size to the top.

By having the small-sized material at the top, the surface area per cube unit is greater than the lower depth, thereby arresting the solids on the surface layer of the filter, where it can obtain a greater amount of oxygen than lower down the filter.

The advantage of having the larger material at the bottom of the filter is the increased drainage effected, as the resistance through friction is much less than it is with the top layer of small material.

Experience has proved that good drainage of the lower portion of a percolating filter is absolutely necessary, and to obtain the best results a smooth-surfaced material, such as gravel, is found to be the most efficacious.

There are many things connected with sewage purification that require elucidation before it can be said to be on a strictly scientific basis; but with the combination of the labors of all those working on the subject, and patient investigation by those working every day on the purification of sewage, this subject may in the future be on as much a scientific basis as many of the industries are to-day.

One who sees a filter every day notices that there are many changes taking place during a year. For instance, at times the surface is covered with a dirty, greyish-colored growth. After a time this gives place to a greenish-colored growth; at another period there is no growth perceivable; sometimes the various growths are in varying-sized patches; also, the amount of humus matter being discharged increases suddenly, and the degree of purification at times is unaccountably affected.

To find out the cause and effect of these changes will no doubt help forward the solving of the problem of sewage purification, and assist in placing it on a scientific basis, so that any sewage works manager who has the courage to tackle the investigation of any one of the changes that goes on in a percolating filter will have his patience well tried, and if successful will be rewarded with the pleasure of having attained something towards building up the science of sewage purification.

Where, as in most instances is the case, the expenditure in the construction of the filters is limited, it is much better to spend money on that portion necessary for the purification, such as the distribution, filtering media, and drainage, than on having artistic walls, as, no matter how pleasant to the eye a set of filters may look, if they do not do the work expected of them, the manager does not derive much benefit from the artistic appearance.

Sewage purification, as regards the liquid portion, has got to such a pitch that, provided the money is forthcoming, any degree of purification can be attained; but the question in my mind is, Can the the same purification be obtained with less expenditure or can a greater quantity be purified with the same purification and the same expenditure?

RUSTING OF IRON.

Wrought-iron work, if not properly cared for in respect to painting, or under conditions otherwise bad, may be expected to rust at a rate which corresponds to the loss of ⅛-inch on each surface for from fifteen to thirty years; but with proper care as to painting, and exclusive of exceptionally bad conditions, it does not appear to waste at any measurable rate. In some instances, upon scraping the paint from girders which had been in use for thirty years, the writer has found, beneath the original red lead, the metallic surface, brigh and clean, showing no trace of rust. Of ordinary steel work the same cannot be said, the common experience being that mild steel is very liable to be attacked by rust. With common care in the bridge-yard during manufacture, such that with wrought iron no after trouble would be noticeable, steel is very liable to show, within a year of being built up, numerous little blisters on the painted surface; any one of these being broken away discloses a small rust-pit. This is more often seen on the flange surfaces (horizontal) than on web surfaces (vertical), but it is probable the position has little to do with the matter, and that it is rather due to the fact that rust has been earlier started on the flange-plates, upon being put through the drilling machines and inundated with slurry, which occurs only to a more limited extent with webs having fewer holes. The heads of steel rivets do not show this tendency to "pit" or to early development of rust. The riveting is about the last operation in making a girder, each rivet being freed of all rust by heating, and quickly coming under the protection of oil or paint.

The Canadian Engineer

ESTABLISHED 1893.

ISSUED WEEKLY in the interests of the CIVIL, MECHANICAL, STRUCTURAL, ELECTRICAL, MARINE AND MINING ENGINEER, THE SURVEYOR, THE MANUFACTURER, AND THE CONTRACTOR.

Managing Director: JAMES J. SALMOND.

ENGINEERING OUTLOOK FOR 1912.

The past year has been an active one for the construction engineer and the contractor. Never before in the history of Canada has there been so much money spent in one year on the extension of railways, installation of water plants, construction of sewerage systems, the erection of bridges, large factories and office buildings as was expended during 1911.

In the Annual Statistical Review of The Monetary Times Mr. E. A. James in a comprehensive manner analyzes the prospects for 1912.

The business activity and expansion have not yet reached in Canada their greatest activities, and, as 1911 exceeded 1910 in this regard, so will 1912 exceed 1911. In the past we have been an agricultural country. Our energy has been directed to the opening of the new lands, and, although this has been expensive, yet the returns have been immediate. To-day we are acquiring the solidity of an older community. We are opening high office buildings, developing rapid transportation routes, highly efficient sanitary schemes, large factories and manufacturing establishments, and extending into the urban, suburban and rural communities the telephone wire and electric circuit.

During 1911 the expenditure of public money on construction work in Canada exceeded $300,000,000, and, with the work not yet completed and the prospective work which will probably be carried out, the figures for 1912 will exceed these by at least $50,000,000.

The city of Toronto, for instance, for extension of railways, bridges and electric light system requires $9,000,000, a third of which will be spent in 1912, or on this item alone $7 per person. The Ontario cities and towns generally are but little behind this high average. Berlin will spend $100,000 on a waterworks system; Chatham will spend $40,000 on pavements; St. Thomas will spend $45,000 on waterworks extension; Hamilton will spend $550,000 on waterworks extension, $500,000 on Hydro-Electric distribution system and $180,000 on pavements; Welland will spend $60,000 on pavements and $20,000 on the water system.

In Western Canada the activity is even greater. Saskatoon will spend on pavements $400,000, sewerage system and extension $300,000. Prince Albert is likely to spend on the power scheme $750,000, while the sewerage system will take $200,000 for its extension. Moose Jaw is planning for extension of the municipal work, the figures being $1,000,000.

Winnipeg, which has spent many millions in municipal improvements, requires $1,500,000 for 1912 for: Pavements, $500,000; sewers, $150,000; waterworks, $100,000; walks, $100,000; subways, $600,000. This expenditure is not required for municipal frills and luxuries, but for absolute necessities in a growing city.

The activities of the West are not confined to the prairie provinces alone. The growth of railway mileage in British Columbia, the extension of the Grand Trunk highways, the development of Pacific ports, all require an expenditure of large sums and compel municipalities to press forward improvements.

Cranbrook will complete the sewerage systems at a cost of $100,000. New Westminster, having completed a $1,000,000 water scheme, have now before the public by-laws aggregating $100,000 covering garbage disposal and sanitary measures, and will likely expend this year on pavements at least $100,000.

Eastern Canada showed unusual activity last year, and the prospect for the present year is even better. The increase in the population in Quebec has been followed

by a general demand for improvements, sewerage and lighting schemes, quicker transportation. The opening of new territories by the Grand Trunk Pacific is creating new activity on the both sides of the St. Lawrence.

In the Maritime provinces the activity has not been so great, but the possibilities of these provinces are being more fully recognized, and the development of water power and the opening of new territories by railways is causing unprecedented activity in construction work. In St. John, N.B., the Government and railways will commence spending $1,000,000 on harbor and docks; Halifax, N.S., will spend on sewers $100,000 and on a standpipe for water $50,000. At this port the Intercolonial Railway will commence in 1912 the $1,000,000 deep water terminal.

With these special cases of municipal expenditure and with the knowledge we have of the probable expenditure of the provinces and by the Dominion on capital account we can arrive at a close approximation of the amount of money that Canada will have to borrow during 1912, in addition to the amount of money that will be spent out of current account.

For Dominion purposes	$35,000,000
For railways, electric and steam...	10,000,000
For municipal improvements	64,000,000
For provincial expenditure	60,000,000

To this large total must be added the amount of money that will be spent out of current revenue, an amount equal, if not in excess of the figures given above. Canada is expanding and developing to-day as is no other nation. Her requirements are great, and it is fortunate that her borrowing power has not yet reached anything like its limit, and the Canadian debentures and bonds, whether municipal, provincial or Dominion, are quickly absorbed in the money markets. So long as this is true, the Canadian engineers and contractors will be the important men in the growing community.

AN EXISTING DANGER.

Fire Commissioner Latulippe and Fire Chief Tremblay, of Montreal, have expressed definite opinions regarding fire precautions and regulations in that city. These, they say, are extremely lax, and will bring home the responsibility for fires in cases where buildings are used for purposes for which they are not designed. The fire commissioner says that if the city were more watchful the number of fires in Montreal could be halved. The fire chief describes the present by-laws as farcical. These points were brought out at the investigation into the fire which occurred at the premises of a garage.

Chief Tremblay stated that the building was in no way adapted for a garage, and was not intended when erected to be put to that use. If such a fire had occurred in any of the great cities of Europe under circumstances like this kind, the parties connected with it would have been amenable before the law. The chief also expressed the opinion that the city by-laws in regard to motor garages were useless, and further, that the system of enforcement of the existing by-laws was not sufficient.

At the conclusion of the taking of evidence, Fire Commissioner Latulippe expressed the opinion that a fire like this kind made it clear that if the city authorities were a little more strict in regard to fire rules and regulations, one-half the fires that occurred might be eliminated. He was in favor of a by-law being passed which would render it a penal offence to provide a building that might prove a fire-trap, or to use a building in such a way as was obviously dangerous in view of the fact that it was put to a use for which it was not intended when built. Such a by-law, suggested Mr. Latulippe, should be made to hold liable all concerned in its construction and use, the architect, contractor and the owner, a provision which would result in enhanced care and greater scruples on the part of all concerned, and would thereby materially diminish the heavy fire bill of the city.

These are matters which cannot be left for innumerable adjourned discussions. It is the duty of the Montreal civic authorities to deal immediately with such a serious phase of the fire waste.

EDITORIAL COMMENT.

Motion pictures were used to illustrate work on placing underground conduits and construction work incidental to this in a recent lecture to the Canadian Society of Civil Engineers. This is the first time to our knowledge that motion pictures have been used for such purposes. There is, no doubt, a wide field for their use along these lines, for they afford a most excellent means of showing methods of construction and design.

* * * *

We draw attention in this issue to an address by Mr. D. H. Browne, which was delivered at the School of Mines dinner, Queen's University, recently. In this address Mr. Browne takes issue with the thoughts expressed by Mr. Crane, who has created such a discussion by his attacks on college education. We must congratulate Mr. Browne on his eloquent and closely-reasoned defense, and we publish it with the hope that it will be widely read.

* * * *

Mayor Geary, of Toronto, has received an answer from Mayor Gaynor, of New York, in response to a letter asking Mayor Gaynor to recommend a competent man for the Park Commissionership for Toronto. In it Mayor Gaynor suggests that he has sufficient to do himself to appoint his own Park Commissioners. We would suggest to Mayor Geary that he endeavor to locate a Canadian for this position. The late Park Commissioner Wilson was a Canadian, and received his training in the Queen Victoria Niagara Falls Park. If Mayor Geary will use a reasonable amount of energy in looking around, he will find competent men to fill this position without advertising in another country.

* * * *

The Dominion Power and Transmission Company, which supplies power to Hamilton, Ontario, is again having trouble with anchor ice at their intake. The city of Hamilton was in darkness a couple of nights last week, all traffic on the street railway and suburban lines being tied up also. Similar trouble last year caused heavy losses to the manufacturers and laboring men there. Where hydraulic power companies are so located that there is liability of interruption of such a nature, means should be taken to have a standby in the shape of auxiliary steam power. Power companies with extensive transmission systems supplying widely-spread territories, with many industries and public utilities dependent on them for power, must of necessity take every precaution to prevent interruption of service. And in many cases the auxiliary steam plant is the only sure way.

THE IDOL OF QUICK RETURNS.*

By David H. Browne.†

There are here at Queen's University some 1,200 students, who have come here to spend from four to six years of their life in the pursuit of some definite object. These students will each spend, perhaps five hundred dollars a year, in railway fares, college fees and living expenses, which means that about $600,000 a year is expended by these young men and women. In addition to this they have during this time surrendered their earning power and become non-producers. We will assume that during eight months of the year these young people are idle, and that their earning capacity is $50 a month. This amounts to a monetary loss of at least $400,000 a year. So that I am quite within the bounds of reason when I say that it costs these students at least one million dollars a year to maintain their attendance at this university.

Now, why do they do this? No one pays out money, none devotes his time, his labor, his ambition in this way without hope of recompense. Ask these boys and girls, and they will answer that they do this in order to be successful in life

Success in life. This means two things, greater earning ability and greater enjoyment capability. The end of life is happiness.

Happiness is not mere Hedonism, not the simple pursuit of pleasure for the sake of pleasure. Happiness means the attainment of man's best, highest, noblest desires. We seek for riches, not for the sake of money alone, but for what we can do therewith to further our physical, mental and spiritual welfare. I take it that these students are here at Queen's in order to gain two things, first the ability to attain a higher position in life, and second the capability to enjoy that position when they have attained it.

The first proposition is then that these students came here with the idea that when they leave college they will be able to earn more and to fill higher positions than if they had never attended college.

Is this correct?

I have here in my hand a pamphlet written by R. T. Crane, President of the Crane Company, of Chicago, which is entitled, "The Futility of Technical Schools in Connection with Mechanics and Manufacturing or Electrical and Civil Engineering." This pamphlet and several others along the same line have been widely circulated. They contain a very violent attack upon the technical schools of the United States, and while the Canadian schools are not mentioned, Mr. Crane's arguments are perfectly applicable on this side of the border. It seems to me that these ideas are false, illogical, and dangerous, but in order to show why I thus deny them, it is necessary first to state Mr. Crane's ideas in order.

Quote Mr. Crane's pamphlet on "Futility of Technical Schools" from page 4 "Importance of starting out in life" to page 7 "However as you cannot."

Mr Crane then goes on to show that a graduate of a technical school will go to work for the General Electric Company for two years in the testing department at [illegible] hour, and will then spend two years more in the engineering department at 27½c. an hour, brings the boys to 27 years of age, at which time, as he says, they will be very lucky if they can go out and secure a job at $3 a day.

Mr. Crane's remedy for this is given in his pamphlet, under the caption. Mr. Crane concludes by accusing the college authorities of sharp practice.

Now, Mr. Crane's attack is directed against American technical schools, but it is reasonable to suppose that his arguments are equally applicable to those on this side of the border.

There are, however, some important points upon which our Canadian schools differ from the American. It is customary in the States to carry a course of nine months, even in some cases of eleven months work. On this side our custom is to limit the class work to a period of five or six months, and to allow the boys to spend three or four months of each year at practical work, in the mine, smelter or shop, according to whatever branch of scientific work the boys intend to make a specialty of. It has been my privilege at the smelter at Copper Cliff, to hire a large number of Canadian students during the summer months. The majority of these are hard-working, diligent, intelligent men, keen to grasp a new situation, and manly enough to accept the discomforts incident to the work, in a cheerful way. We are glad to have them there. Those who make good are always welcome again. Of course, as in any other body of men, there are a few goats. I have had a student come to me after a week's work around the furnace and ask for his time, giving as his reason that he wanted to get away, as he had learned all there was about the work, except the details. He got his time.

But the vast majority of Canadian boys are manly and self-reliant. My only regret is that more of them do not stay with us. Like all other commercial enterprises I know of, we are always hard pushed, to find among our men some men of intelligence and experience to make foremen. I can assure you that such men are hard to find. Many times we have had to put in responsible positions men who were none too well qualified for these positions, simply because no other was available. What we and many other firms need is bright young men who will remain in our employment, even if their present positions are not exactly to their liking, until we have had time to move them from one department to another in order that they may get a broad experience in this work. But very frequently the very man we have talked over and planned to move into some more responsible position, gets another opportunity offered him elsewhere, and when we want him, he is gone. This fact which I wish to emphasize, shows very clearly that the demand for such intelligent work as these boys give is greater than the supply. This fact disposes in very large measure of Mr. Crane's argument that the technical schools turn out a lot of young men who are worthless to their employers, and who can not obtain responsible positions. But Mr. Crane goes on: These technical school men are not fully trained craftsmen, they are not competent along any one line. They come out of college and have to compete with the uneducated laborer, who, by sheer dint of sticking to one line of work, has mastered that line, and is receiving good wages. This is very true. Take a college boy who has studied, say electrical engineering, goes into the shops at Peterboro'. He finds there men who can do the work he is put at far better than he can, men who know nothing but this particular work.

*Address delivered at dinner of School of Mines, Queen's University, Dec. 12th, 1911.

†Superintendent Lake Superior Corporation.

These are his competitors. He has to accept their wage rate, and pit his brains against their experience. He is at a disadvantage for a time. If he considers his present condition only, he may regret that he had not followed Crane's advice, which, you will remember, was to omit the technical school course, go directly into a shop, and spend four years of practical training at one line of work.

Now, all I say to this is that if a boy desires to become a highly efficient machine, this is certainly the best way to go about it. The modern shop is always in advance of the technical school, the surrounding influences are all in one direction, and a young man thus spending six years of his life is undoubtedly a better craftsman, and can immediately earn higher wages than one who has spent four or six years in a university.

We will admit once for all that there are some subjects which a university or technical school cannot teach, does not attempt to teach, and should not be expected to teach. A university does not aim to make machines, but to make men. It does not take a boy and perfect him along one narrow line. It aims to lay broad foundations, to inculcate principles, to train in culture, to foster a taste for all that makes life liveable and men and women lovable.

Take this technical school here for example. If a boy wishes to become a mine foreman, or a smelter man, or an expert winder of commutators, he will never get that training here. Any of your professors would advise to go into the mines at Granby, or the smelter at Copper Cliff, or into the General Electric Works at Peterboro'. In four or five years he would be a skilled craftsman, he would earn three or four dollars a day, he might even be in charge of some commercial enterprise—but that is all. He would be successful as he measures success—but what a price to pay for such a limited success. Like Selkirk on Juan Fernandez, he is monarch of all he surveys, but how far can he survey; how limited his horizon?

Many, many generations have gone by since the preacher said: "Where there is no vision the people perish." Where there is no vision, no broad outlook on life, no scope for larger ambitions. What phrase could better describe the condition of one who spends his best years in mere striving to learn a craft whereby to earn his daily bread.

This is all the training, such as Mr. Crane proposes, can give, the certainty of daily employment. Is this, then, all we are to strive for? Is the training we get here simply a meal ticket?

I claim that life is more than this. Man cannot live by bread alone. Remember that happiness arises not merely from greater earning power, but from greater capacity for enjoyment.

There are schools, exactly such as Mr. Crane describes, where a man can learn to be a telegraph operator, or a stenographer, a watch-maker, or a barber, and at the end of his training course he comes out a brisk, useful craftsman, needing only practice to make him perfect.

But what profiteth it a man if he gain the whole world and lose his capacity for enjoyment? Wherein is he a gainer if he can earn a living, and his life is not worth living? He can wind a commutator, but he has never heard of Franklin or Faraday. He can cut stone or mix paints, but is blind to the smile of the Venus of Milo or the grace of the Sistine Madonna. He can tune a piano, but is deaf to the pathos of Beethoven and the pious exaltation of Handel. He can survey a wilderness into town lots, but has never lifted his thoughts to the Pleiades and the flashing belt of Orion. He has mastered the books of the Scranton Correspondence School, and has never heard of the madness of Hamlet, or the troubles of Tristram Shandy. He can work for a party victory in his own riding, and knows not that his liberty to vote was won by Pyne and Hampden and William the Silent and Stephen Langton. He is living by bread alone. He has no vision, he cannot see the world as a whole, he has bartered his birthright for a mess of pottage, and sold his manhood for a meal ticket.

You are taught here many things which may appear to you dry, tedious, irrelevant, uninteresting. Never mind that. You will forget more than you will remember. But always remember this: it isn't the water that stays in the fleece that scours it, it's the water that goes through the fleece. It isn't always what you remember that does you most good, it is the act of grasping new ideas, of fixing the attention, of facing novel problems, of training your brain to act quickly in emergencies. These studies you grind out here are useful, not solely for what you remember of them, but for what they suggest to you.

Mathematics is not, as the Beloved Vagabond says, a lot of damned facts about triangles, it is the plan on which the Creator fashioned the universe.

Chemistry and biology are not the mere study of reactions and adaptations, they are the keys to all life, past and present. Mining and metallurgy are not hand-crafts, they are the factors that open new continents and change the map of the world. French and English are not simply languages in which to call for another wheel-barrow of concrete, they are the open doors to the literature and history, the wisdom and pathos, the wit and humor of a thousand years.

All this broad outlook on life is summed up in one word —culture. No one can give you this, but every college gives you an excellent opportunity to attain it. Culture, friendship, inspiration—these are the three things that make life worth living, three things which are here for you to grasp and take with you.

Culture, as I have said, comes from the study of broad principles, and can never be attained by undivided attention to one narrow subject. Here in these halls, among these libraries and museums, you have the chance to attain it.

Friendship, the good-will and affection of your fellows is here also for you. You cannot dig this out of dead books. Here around you are young men who may be leaders of the future. Learn to know them, find out the best that is in them, be loyal to them, for as the Norse proverb says: "Back is bare without brother behind it." The loyalty you give to the captain on the campus is the same loyalty that has made Canada a great country, and some day will make it, in name as well as in fact, a great self-governed, self-centered nation.

Inspiration meant the inbreathing of a great spirit, the breath of life in man's nostrils. We cannot define it, we cannot analyze it, we can only feel it, as we feel a chord in music. It comes from the consciousness of the presence of the mighty dead who have moulded the nation, it comes from the companionship of noble men and women living around us, from the memories with which the college halls are hallowed. You know the feeling that comes over you in a close-packed crowd when the leader rises and you see the tense upturned faces around you and hear the quick intake of breath, as the truth he speaks sinks home. You picture the gaunt figure of Lincoln at the National cemetery and the hushed audience that hangs on his words as he gives them the greatest speech ever made in the English language, the matchless Gettysburg address. They turn away, too deeply moved to applaud, too much uplifted to cheer, because they have received the inspiration, they have seen the vision.

There has been in every college some man around whom the highest and noblest ideas have crystallized, men who have moulded the nation, such men are our greatest inspirations. Such men as Arnold of Rugby, Elliot of Harvard,

Wilson of Princeton, Angell of Michigan, are fit companions of the greatest Grant of Queen's. These are the men who have made us men. Can any narrow course of training such as Mr. Crane desires, give us anything for which we would exchange these memories? Never. Man cannot live by bread alone.

You will go from here in a few years less skilled perhaps in the profession you enter than many a trained apprentice, you may earn less for a few years than if you had never come here, you will have your struggles as we have all had, but if you have learned how to be thorough and manly and self-reliant, to be honest and kindly and clean, in a word, if you are true to the tradition of Queen's you cannot fail of success; but when you do attain your ideals you will have brought with you a greater capacity for enjoyment, a broader outlook on life, a nobler patriotism, and a higher ideal than if you had never spent these years at Queen's, for you will take with you somewhat of these three, culture, friendship, inspiration, to broaden and brighten your life, and you will have glimpsed the vision without which the people perish.

CONCRETE SIDEWALKS.

By S. B. Code, O.L.S.

Owing to the superior qualities of cement concrete, as well as to its low cost in comparison with that of other materials formerly used, concrete sidewalks are now almost universally used in every city, town and village. All the requirements necessary in a walk are met with by this material, the chief of which are (1) an even surface, (2) solidity, (3) durability.

Specifications for sidewalk construction are not new, and it is not the intention of the writer in this short paper to give a list of specifications, but rather to deal with the question of what is the best mehod of carrying them into effect.

Some municipalities adopt a system of building their walks by day labor, others the system by contract. In the former case a foreman being employed, in the latter case an inspector looking after the work. The responsibility of the whole work devolves upon either of these men. When the work is done by contract and an inspector is appointed, it has been the experience of the writer that municipal councils are not careful enough about the selection of the inspector. Either they look to the side of cheapness and give the position to the lowest bidder, or else through sympathy or influence on the part of the members engage an incapable. The inspector should be a man of integrity, ability, and beyond suspicion, also possessing some energy, and not one who on a hot afternoon will sit down on a doorstep and go asleep while the contractor is at the same time "making hay while the sun shines."

The possibilities of cement-concrete are probably not fully appreciated, while it is also a fact that defects are to be found in concrete construction, and especially in walks, but these defects may in most cases be traced to lack of knowledge of the materials used in construction, to inexperience in such construction, and to neglect and failure on the part of the builder or inspector, to appreciate the importance of the minor details. Cracks in walks are not always caused by an improperly prepared foundation. A fractional part of a block should not be left over even for suspension of work at the noon hour. This often occurs, and when work is resumed fresh concrete is placed against that laid in the forenoon and a top coat placed over all. The concrete in the separate parts will not properly bond, and the result is invariably a crack in the walk at this place.

To obtain best results only first-class materials should be used. The labor is the largest item but could be saved for laying the walk with poor materials as with good materials. First-class materials, skilled labor, complete specifications, a capable and efficient inspector who will see that the specifications are enforced, should give good results. Very often the inspector is too lax, and carelessness of one kind is encouraged by another. The selection of materials is the first consideration and is an important matter. Portland cement of high grade should be used, the same subjected to a close test, as it is well to take nothing for granted. As more reliance can be placed upon a reputable brand of cement than upon a natural deposit of sand, gravel or stone, it is thus important that the quality of the aggregate should receive careful attention. The surfaces presented by the particles composing the aggregate should be hard and permanent. A covering of any fine superfluous material will interfere with the cement or mortar getting into contact with the surface of the aggregate and thereby reduce the strength proportionately. The aggregates should be well graded and should not contain an excess of one size particles and a small amount of fine particles. The crushed stone should be hard and durable, clean and free from a covering of dust or other matter. In sand and gravel one is dealing with entirely different materials, and materials that should be selected with great care. Shaly particles are undesirable because they are both weak and unstable, and a concrete can never be stronger than the material making up the aggregate. The size of the sand grains and the relative proportion of grains of different size have a very marked effect upon the value of the sand. At least 75 per cent. of a sand should be retained on a 40-mesh sieve with the particles well distributed between that size and the size passing a 4-mesh sieve, with an increasing proportion on the coarser sieves. Such a sand will have much less total surface than one sand made up entirely of fine particles will present a very much larger surface which must be covered with cement than either of the sands above mentioned. The total superficial surface of a given volume of spheres one-eighth of an inch in diameter is four times the surface of the same volume of spheres one-half an inch in diameter. To obtain first-class concrete it is necessary to perfectly cover every particle of sand with cement, and every particle of the coarser aggregate with the cement sand mortar. It is therefore essential that materials with an excess of fine particles should not be used. Compressive strength is in favor of the coarser material. To give the maximum strength and use at the same time the least cement, the aggregates should be so graded as to have each successive size material fill the interstices left by the preceding larger size. It has been found by experiment that aggregates exceeding one and one-fourth inches in diameter should not be used. The lower limit, one quarter of an inch, which is also the upper limit for sand and stone screenings, is almost universally accepted.

The foundation should provide a permanent bed for the walk, and serve as a means for disposing of water which would otherwise accumulate under the walk. It is very important that the foundation should be so constructed that neither time nor the elements can change its ability to support the walk. It is usually necessary to prepare the subgrade, upon which the foundation is established. If the soil at the excavated grade is firm and solid there is no necessity for further preparation, but if it contains any soft, boggy or spongy places, these should be removed and the holes filled with firm material and thoroughly consolidated by ramming or rolling as the filling progresses. The preparation of a fill for the sub-grade requires care. The upper portion of the fill should be tamped in layers not to exceed six inches

in thickness. The sides of the fill should be given a slope of not less than 1½ to 1, so that it will not slip away, and when granular materials are used the sides should be banked on the slope with sod or clay.

Any piece of work is large enough to justify a study of the aggregates for the purpose of determining the correct proportions. It has been stated that the ordinary mixture for water-tight concrete is about 1 part cement, 2½ parts sand and 4½ parts coarser aggregate, which requires 1.37 barrels cement per cubic yard of concrete. The most practical way of arriving at the proper proportions is by the determination of voids, or space that is occupied by air. In order to eliminate the error which might arise from absorption of water in the process of determination of voids, the material, if dry, of porous, should be wetted slightly and afterwards dried so as to remove this moisture from the surface. In the actual process of determining the voids, a cylindrical vessel of metal of 1 cubic foot capacity may be used. The vessel is first weighed and then filled level full of water and weighed again. Call the net weight of the water C. Empty and dry the vessel and fill level full with the aggregate. Call the net weight of the aggregate B. Pour water slowly into the aggregate until the vessel is again level full of water. Call the net weight of the aggregate and water A. The formula then is per cent. voids equals $\frac{A-B}{C}$ 100. To determine voids in sand and stone screenings, the sand should be poured into a vessel containing water. The object in doing this is to eliminate the air, which is impossible if the order is reversed. When the vessel is level full of sand and water, the weight is determined and the formula given for the coarser aggregate applied.

Proper mixing of the materials composing the concrete is very important. Machine mixing has its advantages and its disadvantages. The sand and cement should be first mixed dry and then mixed wet into a homogeneous mortar. The coarse aggregate previously mixed should be added to this mortar, and all thoroughly mixed together. Hand mixing, if carefully done, is entirely satisfactory. Oftentimes mixing is sadly neglected, or is entrusted to unskilled laborers who have little or no appreciation of what is really necessary and less interests in final results. Machine mixing with the batch type of mixer is reliable.

About every fifty feet a good expansion joint should be made. This may be accomplished by replacing one of the wooden cross forms by a metal parting strip, which should be left in the walk until it is open to traffic, when it will be removed and the opening thus produced filled with pitch or other suitable material.

Care should be exercised in adding water to a concrete mixture, because, as is often the case, the water is thrown on a bucket full at a time, and the cement is thereby washed from the mixture. The water should never be added faster than it can be taken up by the materials. When additional water is required in a mixture it is a good practice to add it in a spray.

Concrete or mortar which shows preceptible hardening or drying out should not be re-mixed nor used. Any disturbance of concrete after hardening has begun will weaken it.

Where hand-mixing is made use of the concrete is usually mixed on a water-tight platform, and the size of the batch may be governed by the speed of mixing and depositing in place. Before placing the sub-base should be previously wet and tamped and the concrete deposited immediately after being made, having regard for the preservation of the proper proportions. As the concrete is usually deposited with wheelbarrows, there is a tendency for the cement, being fine, to be carried in suspension with the surplus water away from the other materials. On hot drying days the loss of water by evaporation from the mixture should be prevented, as it forms an essential constituent part of the concrete.

The top finish, when put on separate from the concrete, should be a mixture of one part of cement to one and a half parts of screenings or coarse, clean sand. This should be put on immediately after the concrete has been consolidated. Any time which elapses between the laying of the concrete course and the laying of the finishing course, will seriously interfere with the bonding of the two. The longer the interval the more drying out will take place in the concrete, and there is no assurance that a perfect bond can be attained, except by special treatment, such as cleaning off any dust, sand or foreign matter and applying a wash of neat cement and water.

A very important point in sidewalk construction, and one which is very much neglected, is the making of proper expansion joints. Usually the place for the joint is marked on the edge of each form and an attempt is made at making a sort of indifferent joint by forcing a thin piece of iron or a trowel through the base. This is filled with dry sand. Afterwards the top finish is floated and trowelled and before setting the same tool is driven through the finish in an endeavor to strike the opening in the base. Often, through carelessness, this top mark is not made directly over the bottom mark, but the two marks are some distance apart and the result is invariably a break in the top above the joint in the base. A good joint can easily be made, as stated in the foregoing part of this paper.

After the walk has been completed care should be exercised to protect it from the action of the elements. A covering of canvas or other material is usually used, as too rapid drying in a hot sun is apt to result in checking. After the cement has thoroughly set it is a good idea to keep the walk moist for a time.

STATISTICS OF WATER POWER DEVELOPMENT.

A brief prepared by the public policy committee of the American Institute of Electrical Engineers and presented at the public hearing before the United States National Waterways Commission, Washington, November 21, contains among other statistics the following interesting data:—

"The statistics of water power collected under the direction of Congress several years ago and embodied in the report of the National Conservation Commission of 1909 show that there is at present developed in the United States about 5,000,000 horse-power of water power.

"The amount of power produced by steam from coal is difficult to estimate, but is considered to be about 27,000,000 horse-power, and is rapidly increasing, with attendant depletion of coal reserves. A large part of this it is not only possible but easy for water power to replace if it were made freely available through development. Within range of development at a cost of investment that would make the cost of such power about equal to that of steam power, there is still undeveloped in the streams of the United States about 35,000,000 horse-power.

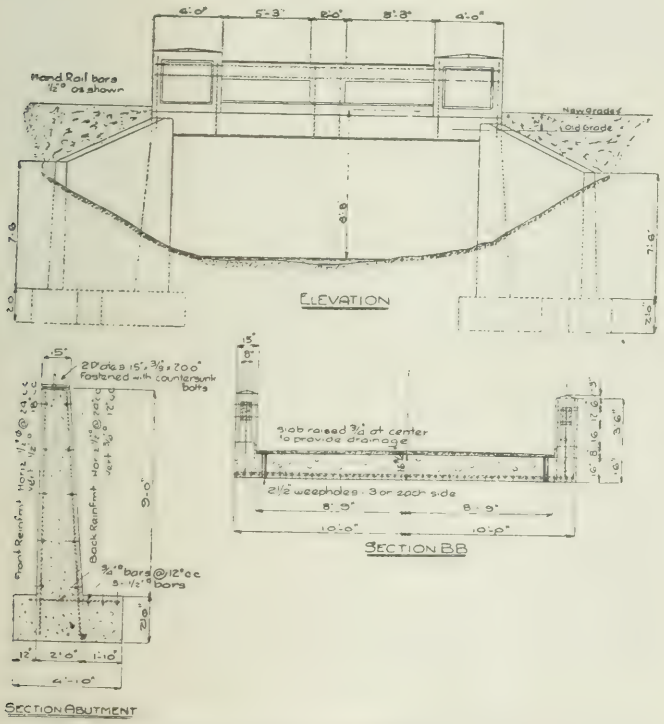
"Any acion by Congress that would accelerate the release of this power would conserve enormous supplies of coal for such domestic and industrial purposes as only coal can supply."

THE CONSTRUCTION OF A MODEL BRIDGE IN IOWA.

The construction of a model bridge is described by Mr. C. B. McCullough, assistant engineer of the Iowa State Highway Commission, in a recent issue of Good Roads. The following is abstracted from the description as being of interest:—

During the past few years, the State Highway Commission of Iowa has devoted considerable attention to the construction of model reinforced concrete culverts and short span bridges throughout the various counties of the State. While the cost of any one of these structures, considered as a unit, is rarely as low as could be desired, their value to the counties from an educational standpoint, and to the concrete industry, is sufficient to warrant a much greater expenditure if necessary.

The construction work has just been completed on a bridge of this kind crossing Wolf creek, in Clay township, Grundy county. The bridge is a reinforced concrete slab of 18 ft. clear span, and a clear roadway of 17 ft. 6 ins. The construction work was done by the county bridge crew under the general direction of the writer, who attempted to keep an itemized and accurate account of the cost of each operation. Because of the fact that very little data of this kind on structures so small as this, has been published, and because the design of the bridge embodies several features such as the use of shop built reinforcement, which should interest every county bridge official, a brief description of the design and an account of the construction is here submitted.



Elevation, Slab and Abutment Sections, Bridge No. 1301, Wolf Creek.

Abutments.—The abutments were designed as simple retaining walls to withstand a horizontal pressure equal to one-third the vertical, including a surcharge of 2 ft. above the bridge seat. The reinforcing in the back and top of footing was made of sufficiently great cross sectional area to withstand the tendency to crack at base of stem, while the bars in the front face were simply a precaution against frost and other action, which would threaten to crack the abutment horizontally in front, should the expansion joint at the bridge seat become defective. While this latter precaution is perhaps not absolutely necessary, it seemed warranted by the number of abutments throughout the state which have developed horizontal cracks for seemingly no other reason. An analysis of the abutment, account being taken of the dead weight of that portion of the slab resting upon it, shows the resultant line of pressure to pierce the base a little outside of the middle third, resulting in a maximum toe pressure of about 4,200 lbs. per sq. ft., and a factor of safety against sliding along the base of about two. In the design, no account was taken of the increased stability due to the action of the wings, although these were positively connected to the body of the abutment by means of the hooking of the reinforcing bars.

Slab.—The slab was designed for its own dead weight plus 6 ins. of earth fill, together with a live load consisting of a 12-ton traction engine, two-thirds of the weight of which was considered concentrated on two rear wheels, 5 ft., centre to centre, and 11 ft. from the front trucks, on which the remaining one-third of the weight is concentrated. The weight on each of these wheels was considered as being distributed transversely over 4 ft.

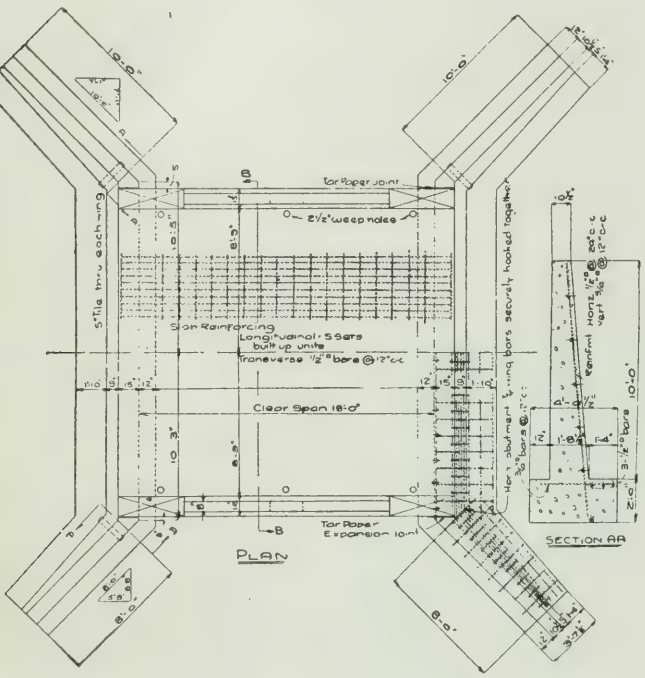
The longitudinal reinforcing for the slab comprised 5 units of shop built reinforcement. These units were fabricated in the shops of the A. E. Shorthill Company, of Marshalltown, Ia., and consisted of ten ¾-in. square, plain, mild steel bars, part of which were bent up at an angle of 30 degrees, at the points shown in the drawing, for diagonal tension. Both the bent and the straight bars were passed through a ⅜-in. rectangular plate at the end, making therewith a positive connection by means of hooking and cold riveting. These units were 4 ft. in width and weighed about 565 lbs. each. They were built and shipped ready to place.

The use of shop built reinforcing eliminates the uncertainty as to whether the bars in the structure really occupy their computed positions, and also rendered the placing of the slab steel comparatively easy, while the use of the plate at the end secured the bars against any slipping due to lack of bond strength at the ends and consequent diagonal tension or shearing failure. The transverse reinforcing was of high carbon twisted square rods, as was practically all of the other reinforcing steel. Provision for drainage of the slab was made by the insertion of six 2½-in. gas pipes through the slab at points indicated on the drawing.

Expansion Joints.—Provision for expansion was made on both ends of the slab by means of two steel plates, 15 ins. by 20 ft. by ⅜-in., placed on top of each abutment with countersunk bolts, bonding them to the concrete. The wings were separated from the slab by means of an ordinary tar paper joint, as shown in the drawing.

The form lumber used was practically all new. Number 1 ship lap, 1 in. by 8 ins., being used for the casing and lagging, while 2 by 12's and 2 by 6's were largely used in the hand rail form work. The studding was of 2 by 4's, spaced 16 ins. centre to centre, and two-ply caps of 6-in. by 8-in. material placed over an existing bent of piling constituted the centreing over which joists of 3-in. by 12-in. county bridge plank, spaced about 14 ins. in the clear, were placed. The lumber was in fairly good condition upon removal, and with reasonable care should be good for the construction of four more bridges. A depreciation of 33⅓ per cent. of the first cost was figured as the cost of the lumber. The tables of cost data give the actual cost of the bridge, no allowance being made for contractor's profit, superintendence, engineering or overhead charges, such as depreciation of mixing plant, etc.

Inspection of the cost data will show that the material ems make up by far the larger portion of the cost of the ructure, about 77 per cent., in fact, while further examina- on will show the hauling charge as being about 35 per ent. of the total material charge. In other words, the ame structure could be erected at the site of the material or $850.39. The hauling was all done by teams over an xceptionally long haul, and the large amount to which this auling expense runs seems to emphasize the desirability f utilizing some form of tractor for hauling of this kind in aces which are situated very far from a railway station.



lan and Wing Section, Bridge No. 1301 ("King" Bridge), Grundy County, Iowa.

Due to the fact that the footings were carried down omewhat deeper than shown on plans, and to other slight hanges, the total yardage was somewhat greater, being bout 92.5 cu. yds. Based on this figure, the total cost er cubic yard was about $12.60, which was exceptionally gh because of the unfavorable conditions.

Some unit costs, based on the actual quantities used, re as follows:—

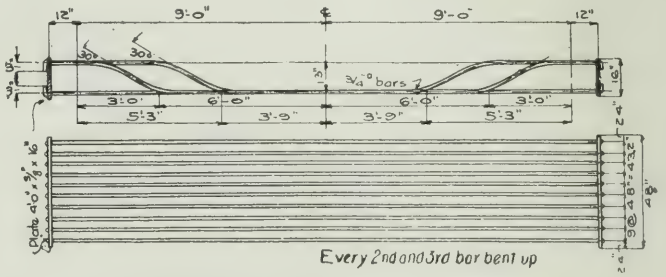
lacing form lumber, per 1,000 B.M.	$7.660
emoving form lumber, per 1,000 B.M.	2.220
lacing concrete, per cu. yd.	.650
lacing steel, per cwt.	.095
'et excavation, per cu. yd.	.850
ry excavation, per cu. yd.	.370
abor on hand rail, per lin. ft.	.620
lacing foundation cribbing, per lin. ft. (perimeter of opening)	.060

Table Showing Labor Costs.

Account	Hours	Rate	Amount
emoving old bridge	6	25c.	$ 1.50
emporary bridge	43	25c.	10.75
ry excavation	22	40c.	8.80
hannel change	10	25c.	2.50
ry excavation	37	25c.	9.25
'et excavation	14	40c.	5.60
'et excavation	154	25c.	38.50
uilding foundation cribbing	33	25c.	8.25
Building forms (not including hand rail)	182	25c.	45.50
Placing and wiring steel (not including slab)	14	25c.	c. 3.50
Mixing and placing concrete (not including hand rail)	231	25c.	57.75
Runaways and platforms	16	25c.	4.00
Placing slab reinforcing	16	25c.	4.00
Painting forms	5	25c.	1.25
Hand rail, building forms	57	25c.	14.25
Hand rail, placing concrete	45	25c.	11.25
Removing forms	56	25c.	14.00
Removing forms	6	50c.	3.00
Miscellaneous (trips to town for equipment)	26	40c.	10.40
Moving plant	30	25c.	7.50
Moving plant	10	40c.	4.00
Total			$265.55

Table Showing Cost for Material.

Item	Amount	Rate	Cost
Lumber (casing and lagging)	3,200 ft. B.M.	$10.00	$32.00
Lumber studding and centreing	4,500 ft. B.M.	10.00	45.00
Cement	163 bbls.	1.68	273.84
Gravel	105 cu. yd.	.50	52.50
Steel	78.7 cwt.	2.16	170.00
Miscellaneous:			
Drain pipes			.50
Form oil			6.00
Hardware, nails, etc			5.00
Cost of material only			$584.84



Detail of Shop Built Slab Reinforcement.

Hauling Material.

Item	Hours	Rate	
Lumber	35	45c.	$15.75
Cement	110	45c.	49.50
Gravel	525	45c.	236.25
Steel	25	45c.	11.25
Total cost of hauling material			$312.00
Total cost for material			897.00

CABLE CONVEYERS.

The Jeffrey Manufacturing Company, Canadian Works, Montreal, Quebec, have recently received orders for four cable conveyers for the Lake Superior Pulp & Paper Co., at Sault Ste. Marie, Ontario. Geo. F. Hardy, mill architect and consulting engineer, is furnishing the designs and specifications.

DIFFICULTIES OF RECORDING CONSTRUCTION COSTS BY USUAL METHODS.*

The statement has been made that the ordinary methods of cost determinations are almost valueless. This applies both to cost keeping as carried out by the builder and to the force account of the supervising engineer. The fundamental reason is that guess work methods have been used in place of accurate scientific methods.

To obtain cost records that are of value to the builder or to the engineer, several essential elements must be recognized, even if methods of unit times are not used. These essentials may be outlined as follows:

(1) Accurate subdivision of the work into distinct operations.
(2) Accurate records of time.
(3) Knowledge of exact quantities.
(4) Proper apportionment of cost of plant.
(5) Proper apportionment of general expense.
(6) Proper apportionment of cost of materials.
(7) Full description of each item of work.

(1) Accurate subdivision of each section of the work into its distinctive operations is of prime importance. The methods described afford the means of dividing the work into its proper elements with great accuracy. The same general scheme of division, however, carried to a lesser degree may be followed in ordinary cost keeping with far better results than have usually been attained.

In the construction of a concrete conduit, for example, the cost records at least should separate the labor into such operations as: Lay invert, place and remove centers, lay the arch, place the reinforcing metal (if any is used), and finish the interior. If fewer divisions than these are made, the total costs obtained may sometimes show the cost to the contractor of this particular job as a whole and may also indicate the probable cost of another conduit of exactly the same design, but these are the limits of their value.

(2) That accurate records are necessary would seem self-evident, but the difficulty in making an exact count of the men at work on the job, and an exact memorandum of the times, is surprising. Generally the men are constantly changing position, and frequently one or more of the men in the gang may have been taken away to fetch material or for some other purpose, so that they are left out in the count. A timekeeper learns to guard against these difficulties to a certain extent, although frequent mistakes are made unless the man is constantly on the spot. The time on force accounts, or even on a contractor's cost keeping records, is often taken by days or half days instead of by hours or quarter hours, and the workman's time is charged to the job he is on when the timekeeper makes his round, so that the returns are inaccurate. In other cases a whole day's work is credited to a certain item even when the men leave before quitting time or change on to other work.

(3) Knowledge of the exact quantity of work performed is as necessary as the recording of the times for doing the work. In certain classes of work differences in the condition of the material affect the quantity. For example, in earth work, or in the handling of sand and gravel, not only is it difficult to measure the quantities, but there is a large percentage of difference in quantity depending upon whether the material is measured in the cut or loose or shaken.

(4) The cost of the plant, including its first cost, depreciation, repairs, and renewals, is an extremely important item and requires careful judgment in apportioning. The factors which must be taken into account in a concrete mixing plant, for example, are the probable value of the plant after the work is complete, the number of days per year in which it can be operated, the time lost in shut-downs for repairs, and the actual cost of repairs and renewals. The cost of tools, such as shovels, picks, etc., must be included in the cost of plant unless otherwise provided for.

(5) On a small job the general expense is readily apportioned. Upon a large job where the work includes, for example, earth excavation, rock excavation, concrete, and riprap (and often several different classes of each) not only the pay for the foreman, but the salaries of the general superintendent, the contractor's engineer, the timekeeper, and the office force (a part of which is sometimes located on the work and a part at the contractor's general offices) must be fully known, and properly apportioned to each class of work. The method that sometimes has been followed of dividing the total general expense by the number of classes of work into which the job is divided is inaccurate, because one class may cost ten times as much as another. The division of cost is difficult because the cost is not known until after the records are taken. A simple method, which is sufficiently accurate in most cases, is to approximately divide the general expense in proportion to the number of men engaged on each class of work. The division need not be made mathematically, but by estimation. The accountant may judge, for example, from inspection of the records that three-tenths of the general expense should go to one class of work, one tenth to another class of work, and so on.

(6) The cost of materials must be divided among the work actually performed. Materials sufficient to last for several months may be purchased during a single week. If this total cost is divided by the number of yards of concrete laid, for instance, in a week or a month, the result will be very misleading. On one job, for example, the unit cost of a certain class of work, as given in the engineer's cost sheets, varied from 73c. in one month to 19c. in another, solely for the reason that most of the materials were purchased the first month and were all charged up to the cost of the work during that month. To provide for this, the accountant should know the approximate amount of material used in a definite quantity of work, and should carry forward the material on hand. If this division is impracticable, the next best way is to keep the material and labor separate, and allow the man who is making up the cost sheets to estimate the cost of the material from his knowledge of quantities.

(7) Lack of description renders many careful records of cost absolutely valueless, except for determining whether a contractor is making money. For example, on one job very accurate records of cost of earthwork were made by the engineers, giving the number of men employed, the number of carts, cost of superintendence, cost of tools, and many other details, while the length of haul or the character of the material handled was not stated. The result was an accurate record of the cost of labor on this particular job, but one which was absolutely useless in estimating the probable cost of other work, of a similar nature, that was being done by the same engineering commission. In another case, the times of the men on all classes of work, including the engineer and other men in the various offices of the contractor, were carefully recorded on large cost sheets. The work included several kinds of concrete construction. One kind was found to cost $4.08 per cubic yard, another kind $6.28, and another kind $7.98, but nothing was shown on these sheets to indicate the reason for these differences. No definite description was given of the character of either job, and the only means of comparing them would have been to look up the contract and the plan, and then probably find that each class covered so broad a range as to provide no

*From "Concrete Costs," by Frederick W. Taylor and Sanford E. Thompson. Copyright, 1912, by Frederick W. Taylor.

definite information. The amount of information required to properly describe any piece of work depends upon its character and the minuteness of the cost or time observation. If simply general costs are being compiled, the analysis of almost any class of work will show that there are a few, perhaps not over a half dozen, essentials which will usually give reason for an apparently low or for an excessive cost. Although, even with such data, cost keeping will not give the exact basis for estimates that may be obtained with the more scientific methods of unit times, the results may be recorded in such a way as to aid materially the judgment of an experienced engineer or a contractor.

STRENGTH AND FATIGUE PROPERTIES OF WELDED JOINTS.

At the meeting of the Institution of Civil Engineers on Tuesday, December 12, Mr. T. E. Stanton, D.Sc., M.Inst. C.E., and Mr. J. R. Pannell, presented an account of some experiments on the strength and fatigue properties of welded joints in iron and steel, which were undertaken at the suggestion of Sir John Wolfe Barry in 1908, the object being to obtain a comparison of certain properties of welded joints —made by different processes and by different makers— with the corresponding properties of the unwelded material from which the joints were made. It was hoped that by this means some estimate of the general reliability and efficiency of modern welding processes might be arrived at. In order to obtain material for the work a circular letter was sent from the National Physical Laboratory to various engineers inviting them to submit specimens of welded joints for testing. Sixteen firms responded to this invitation and the total number of welded joints received was 167. The method of welding and treatment of the joints was left entirely to the makers, the only condition being that all specimens should be made from bars 1¼-in. in diameter. The tests to which the joints were subjected were: First, a tensile test; and secondly, a fatigue test by the Wöhler method. The former included determinations of the elastic limit, the yield point, the maximum stress, the total elongation, and the general and local elongations.

For the rapid carrying out of the fatigue tests a machine was constructed in which the specimen was rotated at a speed of 2,200 r.p.m. Owing to the results of a previous investigation with another type of machine having shown a decided reduction of fatigue strength with increased rapidity of stress-alternation, preliminary experiments were carried out to determine the amount of this effect for the particular type of machine used. The results showed that for speeds of 200 and 2,200 reversals per minute there was practically no difference in the fatigue strength. The assumption was therefore made that the apparent reduction of fatigue strength with rapidity of alternation in the case referred to was a characteristic of the machine used.

The mean results of the tensile tests on the welded joints, expressed as a percentage of the strength of the original material from which the joints were made, were:—

	Per cent.
Hand-welded iron	89.3
Hand-welded steel	81.6
Electrically-welded iron	89.2
Electrically-welded steel	93.4

Joints made by the oxy-acetylene process were also submitted by two makers, but the results were not comparable with those obtained by the hand or electric processes.

The various determinations made in the tensile tests showed a distinct want of uniformity in the material in the region of a weld, but the results of the fatigue tests proved that this does not materially effect its resistance to reversals of stress. When failure under alternating stresses of low value takes place, it is invariably due to a defect in the actual weld itself. The number of defective joints which were discovered in the whole investigation, however, leads to the broad conclusion that in important work, where the failure of any particular welded joint may involve serious damage to the structure, the subjection of each joint to a proof-load is still desirable.

WESTERN MILEAGE OF THE CANADIAN PACIFIC RAILWAY.

By H. M. P. Eckardt.

Canadian Pacific's recent announcement of a new stock issue of $18,000,000, which will bring $27,000,000 into the company's treasury, draws attention to the yearly additions to Canadian Pacific Railway mileage in western Canada. The immigration movement, which assumed its especial importance five or six years ago, is the principal factor in causing western prosperity. This immigration movement has, incidentally, been instrumental in inducing the railways to increase their western mileage. Then, in turn, the policy of active construction of new branch and main line of railroad, has induced more immigration and more prosperity. By means thus of action and reaction, western progress has been steady and rapid. It will be interesting to study the extent of the Canadian Pacific Railway's yearly construction work west of Lake Superior during the period 1905 to 1911.

Before detailing the additions made to the western portion of the system, it will be well to trace the development of the mileage of the whole system. In the following table the summary for the six years is given:

Year.	Mileage in C.P.R. Traffic Returns.	Mileage Other Lines Worked.	Mileage Under Construction.	Total.
1905	8,568.0	438.0	481.4	9,487.4
1906	8,776.9	438.0	923.7	10,138.6
1907	9,153.9	262.4	823.0	10,239.3
1908	9,426.4	261.7	708.4	10,396.5
1909	9,878.5	261.7	403.2	10,543.4
1910	10,270.6	261.7	471.4	11,003.7
1911	10,480.9	291.9	983.3	11,756.1

In the six years the total mileage of the company, exclusive of that pertaining to the Minneapolis, St. Paul and Sault Ste. Marie Railway, and the Duluth, South Shore and Atlantic Railway, increased 2,268.7 miles, or an average of 378.1 miles per year.

In connection with this increase of mileage it is interesting to review the increase of capitalization concurrently taking place.

(Thousands omitted).

Year.	Common Stock.	4% Pref. Stock.	4% Cons. Deb. Stock.	Mortgage. Bonds.	Total.
1905	$98,738	$37,853	$89,200	$55,238	$281,029
1906	105,995	42,719	101,519	41,738	291,971
1907	121,680	43,936	106,045	40,238	311,899
1908	141,534	48,803	115,657	39,621	345,615
1909	150,000	52,696	128,930	39,621	371,247
1910	173,530	55,616	136,711	39,621	405,478
1911	180,000	57,076	142,861	38,648	418,585

Incidentally this table shows one respect in which the Canadian Pacific Railway finances are exceedingly strong. The portion of the capitalization represented by mortgage bonds is relatively insignificant; and it grows smaller every year. In the Canadian Pacific Railway's case there is no danger of decreas-

ing prosperity resulting in the property passing into the hands of the holders of mortgage bonds. More than nine-tenths of the whole capitalization consists of stock in three classes.

Proceeding now to the matter of additions to the mileage in western Canada, we get the follofing table:

Year.	Central Div.	Western Div.	Pacific Div.	Total.
1905	3,129.2	1,270.7	951.7	5,351.6
1906	3,526.4	1,369.3	953.9	5,849.6
1907	*3,438.1	1,364.9	1,093.6	5,896.6
1908	2,938.5	1,983.4	1,077.9	5,999.8
1909	2,905.9	2,146.4	1,077.9	6,130.2
1910	2,934.2	2,509.1	1,070.4	6,513.7

*Decrease due to the disappearance from the table of mileage of Qu'Appelle, Long Lake and Saskatchewan Railway, 253.6 miles, formerly worked by the Canadian Pacific Railway for account of owners.

In the annual report for June 30th, 1911, the mileage is grouped under the new style—according to provinces. It appears as follows: Manitoba Division, 2,353.7 miles; Saskatchewan Division, 1,878.8 miles; Alberta Division, 1,677.9 miles; British Columbia Division, 1,170.4 miles: Total, four western divisions, 7,080.8 miles. Thus the additions to the western portion of the system in the six years amount to 1,729.2 miles. The extensions in the West, constitute more than 76 per cent. of the extensions effected for the whole system.

It should be remembered that the Canadian Pacific Railway expends a portion of its newly raised capital and its accumulated earnings in other things than construction and purchase of new mileage. The steady additions to the steamship fleet absorb a considerable amount of funds; the extensions and improvement of stations and terminal property—notably the enlargement of the Windsor Street Station in Montreal—have required much funds. The building of new hotels, and the extensive irrigation works in the neighborhood of Calgary, should also be mentioned, and the constant increase in number and capacity of the locomotives, cars, and other equipment.

The balance sheet as at June 30th, 1911, showed the company's treasury to be in good condition. There was cash on hand, $34,371,550; temporary investments in government securities, $10,088,734, and current assets (consisting of agents' and conductors' balances, net traffic balances, and miscellaneous accounts receivable) amounting to $8,049,899. These items of the quick assets made up a total of $52,510,183. On the other side of the balance sheet were: Current liabilities (consisting of audited vouchers, pay rolls, and miscellaneous accounts payable), $17,203,651; coupons due 1st July and accrued fixed charges, $1,392,316. The surplus of available assets as at 30th June last therefore amounted to $33,914,216. This, however, represents a fall of about $16,000,000 as compared with the surplus of such assets shown on June 30th, 1910. That perhaps explains the new issue of common stock. The payments on the new stock are to pass gradually into the treasury. Judging from the record of extensions above given, western Canada will have the benefit of a considerable part of the expenditures based upon the increase of capital.

NEW BRUNSWICK.

The close of 1911 finds the people of St. John and of New Brunswick animated by a greater spirit of hopefulness and confidence than at any former period in the history of the province. There have never been at any one time before as many large projects under way, nor as bright an outlook for the development of the resources of the province. Premier Flemming stated recently that $20,000,000 would be spent in the province within the next five years. If we include the expenditure for harbor development at St. John, the Premier's estimate is too small. The St. John Valley Railway will cost $9,000,000. The harbor works at East St. John will cost nearly $5,000,000. There will be another $1,000,000 or more spent at West St. John. The railway from Fredericton to the Queen's County coal fields will cost $1,000,000. The Grand Trunk Pacific will expend considerable money, and there will also be the development of the oil shales of Albert County, the iron mines of Gloucester, and other enterprises of importance.

In view of the brighter outlook, the province will make a more determined and effective bid for immigrants than ever before. The St. John Board of Trade has agreed to subscribe $5,000 to establish a branch of the Imperial Home Re-union Association, which provides funds to enable immigrants already in the province to bring out their families. Branches will be formed in other centres, and the Provincial Immigration Department will co-operate in the work. In addition an agreement has been reached by representatives of the Provincial and Federal governments, under which the Federal government will undertake to induce immigrants to come in larger numbers to New Brunswick, and the Provincial government will undertake to look after them when they arrive.

A Washington concern is willing to erect at St. John a branch factory for the manufacture of paper bottles, provided some local capital is invested in the industry. The Board of Trade has taken up the matter, and it is believed satisfactory negotiations will be concluded.

The government of New Brunswick is negotiating with the Canadian Pacific Railway to have agricultural trains tour the province next spring and summer, giving demonstrations at various points on the modern science of farming, as is already done in the west and in the United States. Such matters as dairy and fruit farming, stock raising and seed selecting, will be given special attention.

While the contract for extensive developments at East St. John has not been signed, the government press publishes semi-official statements to the effect that the contract will be awarded to Norton Griffiths & Company, and that in the spring they will begin work on the breakwater, dredging, wharves, and dry-dock, which together will cost about $8,000,000. The work will cover a period of about five years.

While frozen halibut from British Columbia is being sold on the St. John market, very large quantities of frozen smelts are being shipped from New Brunswick to the American market.

The American lumber market has improved considerably, and orders are being received by local shippers.

The St. John City Council has adopted resolutions providing for a reduction of the assessment on improvements by 50 per cent., and an increase in the assessment on land, especially on vacant lots.

Sir William Mackenzie has purchased one hundred and ninety-two square miles of property in the oil shale areas of Albert County, and he intends to erect there a retorting and distilling plant, such as is used in the shale areas of Scotland. This great project, if carried out, will give employment to thousands of men, and with the natural gas and oil wells and the plaster quarries, will prove a source of enormous wealth in Albert County. The fact that the Canadian Northern Railway interests are investing in the province is in itself regarded as a very significant fact.

The exports by the winter steamships from St. John thus far this season are larger than those for the like period last year, and as usual a considerable portion of the exports are American goods brought to the Canadian port for shipment. The Canadian-Australian line will make five voyages from St. John this winter.

The Kent Northern Railway, which runs twenty-seven miles from Richibucto to Kent Junction, on the Intercolonial Railway, has been purchased by a Toronto syndicate. A local paper says the price was about $100,000. The line is one of the profitable short branches of the Intercolonial.—W. E. A.

Correspondence and Discussion Invited

WROUGHT IRON, BUSHELLED IRON, INGOT IRON.

What is the significance of these terms? The first name is more or less familiar as a name to almost every one; the distinction between the first and second would puzzle many; the third term is becoming more and more familiar to engineers, but the meaning of is not yet generally understood.

Wrought iron is the result of a process in which a good grade of pig iron is worked in a puddling furnace as it is called (the operation of making wrought iron is known as puddling) the impurities, carbon, manganese, silicon, phosphorus, and to a certain variable extent sulphur, being oxidized out to form a slag. Owing to the fact that a high temperature is not attainable in the type of furnace used, the final metal, instead of lying in a molten state on the hearth, is found to exist as small soft globules distributed throughout the slag, the slag and intermixed iron being of a pasty consistency. Large balls of this mass are taken out of the furnace and, while still hot, are submitted to mechanical working, the idea being to squeeze as much slag out of the mass as possible; but in spite of all the squeezing and rolling there is always some slag left in the resultant bars of iron. If the metal be examined, however, it is seen that this slag is distributed evenly in fine lines (see Fig. 1.) and does not seriously interfere with the strength of the iron. The nature of the iron itself is worthy of note. It is extremely pure, the carbon percentage being low and as a consequence the iron is very malleable and ductile.

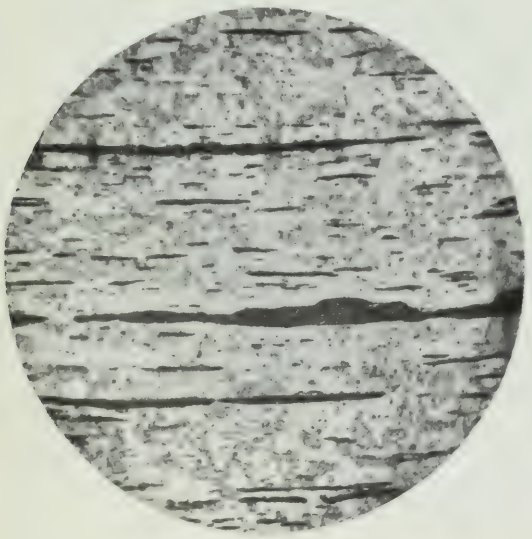

Fig 1.

The processes coming under the head of "bushelling," permitting as they do the utilization of scrap, might be referred to as economizers, but while they undoubtedly have a large and useful field to serve, this field should be thoroughly recognized and adhered to. In short, these processes consist of bushelling, i.e., making up bundles of suitable scrap, and subjecting a number of these piles to the heating action of a furnace somewhat similar in construction to a puddling furnace. When the scrap becomes more or less pasty, it is taken out and worked to a certain extent in the same manner as in making wrought iron. Ostensibly, the idea is to get a product similar to wrought iron, but since the scrap does not undergo the same refining action as in making wrought iron, it follows that if the original scrap is of a mixed quality (as it usually is) the final product will not be homogeneous. Furthermore, examination often shows that the metal contains a great deal too much slag very badly distributed, thus unfitting the metal for a number of structural purposes.

Ingot iron is a very pure form of iron made in an open hearth furnace. In its manufacture, the elimination of carbon and other elements in the original metal is carried on to a much greater extent than in the making of ordinary low carbon steel, the final product containing less than .06% total impurities which is remarkably low. Thus we get a metal that is almost pure iron, and since it is made in an open hearth furnace in which a very high temperature may be obtained, the final metal exists in a molten state and can therefore be tapped out and cast into ingot form—hence the name ingot iron.

Keeping in mind these general outlines, it is comparatively easy to arrive at a conclusion as to some of the uses to which the products under discussion may be put. A consideration of a few of the principles that seem to underlie the cause of corrosion in iron will perhaps give us a better understanding of the discussion.

At the present time the evidence seems to point to the fact that the purer iron is the less likely to corrode. (The presence of manganese seems to enhance the corrosive actions.) Not only does the purity of the iron have a great effect, but the homogeneity also seems to be a great factor. The more homogeneous the iron or steel is the less likely it seems to be open to corrosive action. It is obvious, of course, that the purer the iron is the more likely it is to be homogeneous.

From the standpoint of resistance to corrosion, it is easy to see why wrought iron, being a very pure form of iron, might be specified in construction work. On the other hand, the bushelled product, with its lack of homogeneity, seems to be anything but suited to resisting corrosive action.

A knowledge of such facts as these has led engineers to be extremely careful these days when specifying wrought iron, especially as the true wrought iron industry seems to be on the wane in America in spite of production figures that are given out. (It is lately pointed out by good authority that these figures must include, in many cases, the product of the bushelling furnaces.) One often wonders why, if there is a demand for good wrought iron, the American firms do not protect themselves by stamping their iron, as do the English and Swedish makers. It is argued, of course, that a stamp is easily copied or wrongly used, but this merely adds force to the claim that, as far as wrought iron and the bushelled product are concerned, there is a loose tendency in America. This is augmented by the fact that in many cases the buyer is indifferent. The bushelled iron does the work just as well as the pure wrought iron, there being nothing at stake in most cases, and besides it is cheaper.

Through the tangle, though, there appears a good solution to the whole problem. If purity and homogeneity in the iron are what are desirable, the products to which we may give the name ingot iron seem to be admirably suited to the case. The name "ingot iron" has been used as a trade name, but a broader significance than a mere brand should be placed on it. If the corrosive question is to be solved, it would seem at present that it must be done so by using these pure irons (in reality very pure steels) made in open hearth furnaces. To such irons as these then, let us apply the term ingot iron. Be the outcome on this point what it

may, it behooves the engineering public to investigate thoroughly the general good qualities of such a product as herein outlined as ingot iron."

THE PRESERVATION OF IRONWORK.

Ironwork enters so largely into the everyday life of municipal engineers, and is used in so many forms in works of construction, that a little consideration given to the methods and need for its preservation may be of service in understanding the principles that are involved.

William Ransom in The Surveyor and Municipal and County Engineer sums up some of the principles underlying the preservation of ironwork from rusting as follows:—

The oxidation or rusting of iron is not due simply to the combination of iron and oxygen. Iron under ordinary atmospheric conditions will quickly rust, but in the presence of dry oxygen will remain bright for a long time. Rusting appears to require not only air, but moisture and carbonic acid. Lime will prevent iron rusting quickly, because it absorbs the carbonic acid which is always present to some extent in the atmosphere.

During the process of rusting ammonia is formed through the nitrogen of the air combining with the hydrogen of the water. The oxide of iron, or rust, as it forms, sets up a galvanic action with the unaffected metal, and although a very weak current of electricity is produced, it decomposes the water, allowing the hydrogen to combine with the atmospheric nitrogen. This galvanic action causes the corrosion of ironwork to proceed with increasing rapidity, after rusting has once been allowed to commence.

The action of water upon iron depends largely upon the presence of carbonic acid. In the presence of sea-water the iron may be dissolved without the formation of visible rust. Sewage matter has a greater action upon iron than ordinary water, probably due to the presence of sulphides.

One of the principal causes of accelerating rusting is electrolysis. When the iron is brought into contact with another metal in the presence of a solution or atmosphere through which an electric current can pass, one metal will decompose. When iron railings are fixed by means of molten lead, the iron will decompose, especially if moisture be often present. This action can be seen in almost all cases where railings have been thus fixed for any length of time.

It will thus be realized how necessary it is that ironwork which has to do duty for many years should be preserved from rusting. In works of construction, unless precautions were taken, the strength of ironwork would speedily be reduced below the factor of safety.

Ironwork can be protected from rusting by (1) coating with oxide films, (2) coating with paint or varnish, (3) coating with some other metal, and (4) enamelling.

(1) When super-heated steam is allowed to pass over red hot iron the water vapor is decomposed, the oxygen combines with the iron, and the hydrogen is liberated. The oxide which forms on the iron makes a protective coat or film against future oxidation. This has become known as the Bower-Barff process, from the two manufacturers who most successfully applied the process. The oxide which is formed is the magnetic oxide Fe_3O_4. If the coat or film becomes broken, or is imperfectly formed, galvanic action would cause corrosion of the iron.

(2) Ordinary paint will form a preservative for ironwork, especially when the base used for the paint is red oxide of iron. Red and white lead are both used, but are likely to be acted upon by carbonic acid gas, etc., and galvanic action also may occur. Paint should be applied to cast-iron as soon as possible after it has been [illegible] before rust has had time to form. The cast-iron should first receive a coat of linseed oil before the paint is applied cold. Various patent preparations [illegible] are now on the market for the preservation of iron. These are largely used for the painting of railings and outdoor ironwork, and are found to last longer than ordinary paints.

Bituminous varnishes are most commonly in use for the preservation of iron pipes, etc. They consist of various mixtures of coal-tar, pitch, linseed oil, resin, and the like. Dr. Angus Smith's process is the best known, and consists of first cleaning the iron, heating to 700 deg., and then dipping for fifteen or twenty minutes into his mixture at a temperature of between 300 deg. to 400 deg.

(3) Iron can be coated with another metal—such as zinc or tin. Iron is coated with zinc by the process of galvanizing, which consists of first cleaning the iron by steeping in an acid solution, and then plunging into molten zinc, which forms a protective coat to the iron. If, however, the zinc be worn off or the coat imperfectly formed, galvanic action is set up, which will corrode the zinc. Zinc is very readily acted upon by acids, and is therefore not suited to manufacturing districts. When iron is coated with tin, if galvanic action is allowed to set up, the iron is corroded.

(4) Enamelling is only of value for iron articles used for domestic purposes, and consists in applying a pottery glaze, which should contain very little lead. Where the enamel becomes chipped the exposed iron will quickly rust and cause further disintegration of the enamel.

CAST-IRON AND STEEL PIPE.*

By Nicholas S. Hill, Jr.

My remarks will be confined, as were those in the paper under discussion, to the relative value of cast-iron and steel for large supply mains, as nothing has been developed which so readily adapts itself to street distribution mains of smaller size as does cast-iron.

In first cost steel mains of large size are cheaper than cast-iron mains. As a rule they are more easily handled because lighter.

The question of strength is one of design; and in making comparisons it should be assumed that both the cast-iron and riveted-steel pipe will perform the function for which they are designed.

From the data available, it appears that the cost of maintenance and depreciation on cast-iron pipe is less than on riveted-steel pipe. The data at hand, however, is not sufficient to enable one to say definitely that the difference is sufficiently great to offset the difference in interest charges resulting from the additional first cost of the cast-iron pipe. Interruptions to service where a community depends upon a single supply line, resulting from repairs as a result of corrosion, are usually of more importance, however, than the mere consideration of cost.

Experience has shown that the more nearly steel approaches a pure iron, the longer it resists corrosion. The properties of wrought-iron are the nearest approach to pure iron, notwithstanding its slag. This is because the slag is mechanically mixed and does not interfere with the chemical properties of the product.

Investigations by a Committee of the American Society of Testing Materials have failed to produce any conclusive

*Abstract of discussion of paper by Mr. Allen Hazen, M. Am. Soc. C.E., read before the American Water Works Association in June, 1911.

evidence with regard to the relative rapidity with which wrought-iron and steel corrode; so many elements seem to affect the rate of corrosion. Field experience, however, indicates that the riveted pipe of wrought-iron is more resistant than steel. In considering this question, it must be remembered that it is difficult to obtain wrought-iron plate at this time, and that in specifying riveted pipe, low carbon steel should be considered.

Cast-iron is more highly resistant in corrosion than either steel or wrought iron. Every examination which I have made of steel and cast-iron mains, laid under the same conditions, has fairly demonstrated the greater resistance of cast-iron pipe to corrosion.

The greater resistance of cast-iron to corrosion than steel is probably due, in a large measure, to the silicious coating which it receives when the molten metal is poured in the mould. The silicious coating adheres very firmly to the pipe. Also the roughness of the exposed surface of the cast-iron offers a firmer foundation for the coating than does the smooth surface of the steel pipe, and hence the same coating applied to cast-iron is usually more durable than when applied to steel pipe.

We have much data with relation to the life of cast-iron pipe. We know that it is good for a hundred years when properly coated, and under almost any condition of soil. There are instances of much longer life.

The intake pipe at the first pumping station for supplying Paris (which extended into the River Seine, and which was laid in 1802), after an immersion lasting for over a century, was recently removed and was found to have been in such good condition that it might have been relaid. The lettering on the pipe was not disturbed. Instances of cast-iron pipe laid in Europe as early as 1765, which is now in serviceable condition, have been recorded. The speaker has removed cast-iron pipe from low ground saturated with a salt solution which had been in service since the early part of the last century and which was in excellent condition when removed. There appears to be no practical limit to the endurance of cast-iron pipe and its resistance to ordinary corrosion.

In considering the effects of corrosion, reference must be made to the effects of chlorides, nitrates and sulphates, which are found in soils of high organic content, and in marsh lands adjacent to salt water. Weak solutions of these salts will produce harmful effects, proportionate to the rapidity with which a material will corrode. A minute quantity of soluble salts is sufficient to start corrosive action and a material which is liable to corrosion should not be placed therein.

Reference has been made to the life of cast-iron pipe. Experience with riveted-steel pipe is very much more limited but there are examples which tend to show that lines of riveted-steel pipe, constructed within the last twenty years, have materially depreciated and great trouble has been experienced from the effect of corrosion. These effects seem to proceed more rapidly in clay soils and marsh land than in sand. Among the pipes which have thus been affected, is the second Hemlock Lake conduit, in Rochester (N.Y.), which was laid in 1893; the Portland (Ore.), conduit, the Atlantic City conduit, and certain conduits laid in the marshes of the Hackensack meadows in New Jersey.

Electrolysis is manifestly more rapid on steel pipe than the cast-iron is several times as thick, will, owing to the rapidly than cast-iron, and electrolysis may be defined as a more serious form of corrosion, occurring where an electric current leaves the pipe and which, in so doing, sets up corrosive electrolytic action.

Rolled steel plates, as compared with cast-iron, although the cast-iron is several times as thick, will, owing to the higher conductivity of steel, have from one to three times the conductivity of a cast-iron pipe designed for the same pressure. This is important, as the electrolytic action is mainly dependent upon the volume of the current, and hence in territories where street railway currents are returned over pipe lines, the riveted-steel pipe offering a better conductor will carry more current, and hence electrolytic action will be aggravated on this account.

There are few places of any size, in which the suburbs are not, at the present time, traversed by numerous suburban lines. If the mains pass in the vicinity of these lines, they may absorb their proportion of the return trolley current and deliver it to the ground at some point nearer the power station. This was clearly demonstrated to me in a recent survey of certain steel and cast-iron pipe lines laid in the marshes of the Hackensack meadows. I found that these pipes were carrying quite an appreciable quantity of current from distant points to the power station, and that they were unloading it in the marshes, to be returned through the saturated soil, to the power station. The result of these surveys indicated the superior conductivity of the steel pipe, and the much greater corrosion resulting from the effects of electrolytical action, than in the case of the cast-iron mains.

In summing up, it may be said: (1) That where first cost is of prime importance, steel may be used on large supply mains. (2) Where the difficulties of transportation are serious and the cost of hauling is heavy, expediency may call for the use of this material. (3) In sections where dry sandy soil is encountered, one would be justified in securing the benefit of reduced first cost by recommending steel pipe. (4) In clay and wet soil, such as marsh lands and meadows, particularly where the presence of salts in solution increases corrosion riveted-steel pipe should not be used. (5) Where pipe is laid in wet soil and will be subject to electrolysis, cast-iron should be used. (6) Where permanency is a prime consideration, our present knowledge indicates that cast-iron is preferable.

THE INFLUENCE OF ELECTRICAL SMELTING OF IRON ORE ON THE SWEDISH IRON INDUSTRY.

At a discussion on the above subject which took place at the Jubilee Meeting of the Technical Association, at Stockholm, the following views were expressed:—

Mr. Arvid Johansson said that the whole of the present pig-iron output might easily be produced by the aid of 180,000 h.p. By adopting electrical smelting this would mean that 60 per cent. of the total quantity of charcoal now used could be saved. The Province of Norrbotten, or the northern part of the country, on the whole offered the widest scope for the development of electrical smelting, (1) because the iron ore was cheaper there; (2) because there were fewer consumers of the available electrical energy; and (3) because there was a cheaper supply of charcoal. The central part of Sweden also offered a vast field for electrical smelting. For instance, after harnessing the Dalelfoen only (the valley river), there would be 250,000 h.p. available for industrial purposes, of which 135,000 h.p. would belong to the Stora Kopparberg Company.

Major-General Geijer (Vice-Chairman of the Grängesberg Company) expressed great faith in the development of an electrical iron industry in Norrland. In regard to Norway, he thought that country was placed at a disadvantage in regard to its capacity to compete with Sweden, chiefly owing to the higher percentage in sulphur of the Norwegian iron ores.

Director Stridsberg, of the Trollhättan Works, said that after the completion of the Trollhättan Canal, which would connect the central parts of the country with the sea, there would be no difficulties in the way of a large export trade in pig-iron to be started. He was an advocate of placing a tax on ore for export.

Director Hult pointed out that the iron industry in Central Sweden was threatened with keen competition from the iron-sponge process at the Höganäs Works.

Director Sahlin called attention to the imports of German pig-iron, which were steadily on the increase.

Director Amilin emphasized the injurious policy of utilizing semi-products from abroad, whereby the quality of Swedish goods would suffer.

Director Wahlberg, of Fagersta, did not share this pessimistic opinion, and thought that the Swedish iron-masters were not so easily led astray.

NEWS ITEMS.

It has been reported that cinnabar has been recently found in the Porcupine region. Cinnabar, the ore of mercury, would be a lucky find in the district mentioned.

We have an enquiry for a second-hand analytical chemist's balance. Address replies to Editor "Metallurgical Comment."

MONTREAL STREET RAILWAY.

It is generally allowed that the complaints which began to be heard some time ago against the Montreal Street Railway were probably the outcome of the change of ownership of the railway. There is no denying that the service is becoming gradually less effective, and that, at the present time, it is less satisfactory perhaps than ever before since its electrification. During the last fiscal year of the company, the number of tickets and transfers amounted to upwards of 150,000,000, this being an increase of some 15,000,000, or 10 per cent. on the number collected in 1910. During the same period it is hardly likely that the efficiency of the railway increased ten per cent., so that though the company operated fully as many cars and as good cars as during the last year of the old regime, and operated them as rapidly as the previous year, the congestion would still be approximately ten per cent. greater. It is not thought that the company added to its rolling stock and otherwise increased its efficiency proportionately with the increase in population. In reality, this question of increase in population in Montreal raises some very serious considerations. The price of real estate has advanced considerably during the past year, which one must attribute in large part to incoming population.

In the vicinity of Montreal houses are being erected in all directions, extending for miles out into the country wherever any sort of tramway connection can be had. This makes the work of the tramway company much more difficult than it was a few years ago. The fear in Montreal seems to be that some considerable expenditure may be put out upon schemes for more rapid transit, which will become almost totally inadequate before they are finished. Meantime nothing is being done, and the car lines become more crowded daily and the citizens experience ever-increasing difficulty in getting accommodation.

A resolution was adopted by the special civic committee having charge of this street railway question during the past week, by which it is proposed to ascertain how many large cars the tramway company is employing on its routes, the total number of cars available, and the number of improved cars which have been added during the past five years. Certain questions concerning less frequent stops will be asked, and suggestions will be made as to new streets and new plans to facilitate the operation of cars. Among citizens the [illegible] of these suggestions to meet the situation which is [illegible] keenly felt.

WINNIPEG BUYS AMERICAN CEMENT.

Last week the Board of Control in Winnipeg accepted the tender of the Lehigh Portland Cement Company of Chicago for 25,000 barrels of cement to be delivered as required in 1912. The tender of the Lehigh Company, the lowest of five submitted, will give Winnipeg its cement supply for next year at a net price of 60 cents per 100 pounds net weight, laid down in Winnipeg, excluding sacks, which will be returned at the cost of the manufacturer. This means a saving of 14 cents per barrel of 350 pounds on the price paid during the present year.

The actual price which the city will pay the Lehigh Portland Cement Company of Chicago for its supply next year may be less than the price submitted, as the company has agreed that if there is any reduction in duty or any revision of freight rates, the city will be given the benefit of reduction. This, it is understood, will include the rebate of two cents per barrel on sacks returned to the United States, which it is expected can be collected, and if this is done will increase the saving over last year's prices to 16 cents per barrel.

PERSONAL.

Mr. A. J. Latorned, city engineer for Edmonton, Alta., has forwarded his resignation to the municipal commissioners. Mr. Latorned cites an offer from another city as his reason for resigning.

Dr. J. W. S. McCullough, Provincial Health Officer, and Mr. N. J. Ker, City Engineer of Ottawa, are on a tour of the principal United States cities, inspecting water and sanitary methods. The City of Ottawa is preparing to install water and sewage systems that will in the future protect the citizens from a recurrence of a typhoid outbreak such as the one of last year, and the information gathered by Dr. McCullough and the city engineer will largely determine the kind of system to be constructed. In Ottawa Dr. McCullough and City Engineer Ker will consult with Mr. Allen Hazen, the sanitary expert.

Mr. Arthur St. Laurent, deputy minister of public works and engineer in charge of the Georgian Bay Ship Canal, has left Ottawa in company with Mr. Coultlee, the assistant engineer of the Georgian Bay Ship Canal, for Panama, via New Orleans. The object of the two engineers is to examine the works and obtain information that may be useful when the Georgian Bay Ship Canal is placed under construction. The two gentlemen will be absent from Ottawa for six weeks, and during that time will consult with all the eminent engineers who made possible the opening of the Panama route, as the latest machinery and appliances for work of that kind are at the canal. Mr. St. Laurent and his assistant will make a report on them.

Mr. F. A. Yerbury, formerly with the Canadian Boving Co., Ltd., has severed his connection with that company, having accepted an appointment with a new company in Vancouver, known as the Heaps Engineering Co., Ltd., the president of which is E. H. Heaps, a gentleman well known throughout British Columbia, from his long connection with industrial concerns there. This new company will install rolling mills, and probably will put in the first electric steel making furnace in Canada of the well known Gronwell type. They will also manufacture motors of the internal combustion type for marine and automobile purposes. Mr. Yerbury will be remembered as the man who had the privilege of introducing the Diesel engine into Canada, of which there are quite a number now in successful operation.

FORESTRY CONVENTION.

The members of the Canadian Forestry Association and others interested in forest conservation will on February 7th and 8th, 1912, gather in Ottawa to discuss what they hope will be the most practical programme of any of their conventions.

H. R. H. the Duke of Connaught evinces his interest in the subject by extending his patronage to the gathering, and the concern of the government is shown in the fact that the meetings will be held in the Railway Committee Room of the Parliament Buildings, and that a number of parliamentary leaders will be in attendance. The railways have granted special rates.

On the evening of February 7th a banquet in which the members of the Canadian Lumbermen's Association will participate with the Forestry Association, has been arranged. The lumbermen will hold their annual meeting in Ottawa on February 6th, and it is expected they will attend in large numbers to discuss with the members of the Forestry Association matters respecting fire protection, logging methods and regulations which vitally affect them, and which are also of concern to every taxpayer in Canada.

Details are now being worked out by the committee in charge, of which Mr. James Lawler, Canadian Forestry Association, Ottawa, is the secretary, and from him may be obtained any needed information.

COMING MEETINGS.

THE AMERICAN INSTITUTE OF CONSULTING ENGINEERS.—January 16th, 1912, Annual Meeting, Aldine Club, Fifth Avenue and 23rd Street, New York City, at 8 p.m. Secretary, Eugene W. Stern, 103 Park Ave., New York.

CANADIAN FORESTRY ASSOCIATION.—February 7th and 8th, 1912. Forestry Convention Meetings held in the Railway Committee Room, Parliament Buildings, Ottawa. Secretary, Mr. James Lawler, Canadian Bldg., Ottawa.

CANADIAN LUMBERMEN'S ASSOCIATION.—February 6, 7 and 8, 1912. Annual Meeting to be held at the same time and place as the Canadian Forestry Association.

THE CANADIAN SOCIETY OF CIVIL ENGINEERS.—Jan. 24, 25, 26, 1912, General meeting, 413 Dorchester St. West, Montreal. Prof. C. H. McLeod, Secretary.

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, C. H. Rust; Secretary, Professor C. H. McLeod.

QUEBEC BRANCH—
Chairman, P. E. Parent; Secretary, S. S. Oliver. Meetings held twice a month at Room 40, City Hall.

TORONTO BRANCH—
96 King Street West, Toronto. Chairman, H. E. T. Haultain, Acting Secretary; E. A. James, 57 Adelaide Street East, Toronto. Meets last Thursday of the month at Engineers' Club.

MANITOBA BRANCH—
Secretary E. Brydone Jack. Meets every first and third Fridays of each month, October to April, in University of Manitoba, Winnipeg.

VANCOUVER BRANCH—
Chairman, Geo. H. Webster; Secretary, H. K. Dutcher, 319 Pender Street West, Vancouver. Meets in Engineering Department, University.

OTTAWA BRANCH—
Chairman, S. J. Chapleau, Ottawa; Secretary, H. Victor Brayley, N. T. Ry., Cory Bldg.

MUNICIPAL ASSOCIATIONS.

ONTARIO MUNICIPAL ASSOCIATION.—President, Chas. Hopewell, Mayor, Ottawa; Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

UNION OF ALBERTA MUNICIPALITIES.—President, H. H. Gaetz, Red Deer, Alta.; Secretary-Treasurer, John T. Hall, Medicine Hat, Alta.

THE UNION OF CANADIAN MUNICIPALITIES.—President, W. Sanford Evans, Mayor of Winnipeg; Hon. Secretary-Treasurer, W. D. Lighthall, K.C., Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer, J. W. McCready City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. E. McMahon, Warden, King's Co., Kentville, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secretary, Mr. Heal, Moose Jaw

CANADIAN TECHNICAL SOCIETIES.

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang; Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BUILDERS, CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Charles Kelly, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto.

CANADIAN ELECTRICAL ASSOCIATION.—President, N. W. Ryerson, Niagara Falls; Secretary, T. S. Young, Canadian Electrical News, Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, Thomas Southworth, Toronto; Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President. Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; J. Keillor, Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. Frank D. Adams, McGill University, Montreal; Secretary, H. Mortimer-Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, T. A. Starkey, M.B., D.P.H., Montreal. Secretary, F. C. Douglas, M.D., D.P.H., 51 Park Avenue, Montreal.

CANADIAN RAILWAY CLUB.—President, H. H. Vaughan; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, D. McDonald, Manager, Montreal Street Railway; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto, President, G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July, August.

DOMINION LAND SURVEYORS.—President, Thos. Fawcett, Niagara Falls; Secretary-Treasurer, A. W. Ashton, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, W. B. McPherson; Corresponding Secretary, A. McQueen.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President, Killaly Gamble; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian Members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain, and W. H. Miller, and Messrs. W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary, R. C. Harris, City Hall, Toronto.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C.B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, W. H. Pugsley, Richmond Hill, Ont.; Secretary, J. E. Farewell, Whitby.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, J. Whitson; Secretary, Killaly Gamble, 703 Temple Building, Toronto

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, F. S. Baker, F.R.I.B.A., Toronto, Ont.; Hon. Secretary, Alcide Chausse, No. 5 Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Alfred T. de Lury, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Dr. A. McGill, Ottawa, President; Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, J. P. McRae; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Wm. Pierce, Calgary; Secretary-Treasurer, John T. Hall, Brandon, Man.

WESTERN CANADA RAILWAY CLUB.—President, Grant Hall; Secretary, W. H. Rosevear, 199 Chestnut Street, Winnipeg Man. Second Monday, except June, July and August at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc.
Printed forms for the purpose will be furnished upon application.

TENDERS PENDING.

In Addition to Those in this Issue.

Further information may be had from the issues of The Canadian Engineer referred to.

Place of Work.	Tenders Close.	Issue of.	Page
Medicine Hat, Alta., church	Jan. 20.	Dec. 28.	59

Woodstock, Ont., church	Jan. 15.	Dec. 21.	59

TENDERS.

Hamilton, Ont.—Plans have been prepared and a company is being organized to turn the old St. Lawrence Hall property into a modern apartment building.

Montreal, Que.—Tenders will be received until January 9, 1912, for 3,000 tons of unbroken macadamizing stone and 6,000 tons of unbroken concrete stone. Copies of specifications may be obtained upon application to Mr. F. W. Cowie, Chief Engineer. David Seath, Secretary Harbor Commissioners of Montreal, Montreal.

Ottawa, Ont.—Tenders will be received until January 15, 1912, for supplying 10,000 cubic feet of round yellow spruce in the log, and 40,000 cubic feet of round white pine timber, all in accordance with specifications prepared by the Dept. of Marine and Fisheries, delivered at Sorel, P.Q. Specifications, etc., can be obtained from the Purchasing and Contract Agent, Dept. of Marine and Fisheries, Ottawa, and from the Director of Shipyard, Sorel, P.Q. Alexander Johnston, Deputy Minister of Marine and Fisheries, Dept. of Marine and Fisheries, Ottawa.

Ottawa, Ont.—Tenders will be received until January 15, 1912, for the construction of a wharf at Anse Aux Canards, Gaspe Co., Que. Plans, etc., may be seen at the office of the District Engineers, Quebec, Montreal, and on application to the Postmaster at Newport, Que. R. C. Desrochers, Secretary Dept. of Public Works, Ottawa.

Ottawa, Ont.—Tenders will be received until January 15, 1912, for the delivery of Indian supplies during the fiscal year ending the 31st of March, 1913, duty paid at various points in Manitoba, Saskatchewan and Alberta. Particulars may be had on application to J. D. McLean, Asst. Deputy and Secretary, Dept. of Indian Affairs, Ottawa.

Ottawa, Ont.—Tenders for the construction of a public wharf at New Liskeard, District of Nipissing, Ont., will be received until January 10, 1912. Plans, etc., may be obtained at the offices of J. G. Sing, Esq., Dist. Engineer, Confederation Life Bldg., Toronto; on application to the Postmaster at New Liskeard, Ont., and at the office of R. C. Desrochers, Secretary Dept. of Public Works, Ottawa.

Toronto, Ont.—Tenders will be received by the chairman of the Board of Control, until noon Tuesday, January 16th, 1911, for the supplying and driving of timber sheet filing at the Sewage Disposal Works site. G. R. Geary, Mayor, Chairman Board of Control, City Hall, Toronto. (See advertisement elsewhere in the Canadian Engineer).

Victoria, B.C.—Plans for the new steel bridge to span the South Thompson River at the city of Kamloops are completed and it is expected that tenders for the erection of the structure will be called for very shortly.

Walkerton, Ont.—Tenders will be received until January 23, 1912, for the erection of a steel bridge over the Saugeen River, 10th Concession, Township of Brant. Bridge to consist of two spans of 125 feet each and one span of 90 feet, or two spans of 165 feet, 16-ft. roadway and with concrete floor. Specifications may be seen at the office of James Warren, Engineer in Charge, Walkerton.

CONTRACTS AWARDED.

Hamilton, Ont.—The contract for the glass factory for the Diamond Flint Glass Co. on James street north, has been awarded to the H. L. Dickinson Construction Co., Pittsburg, Pa. Estimated cost, $40,000.

Montreal, Que.—The Board of Control have awarded to Messrs. T. Lessard & Son, the contract for the construction of a fire and police station in Villeray, for $72,000.

Halifax, N.S.—The Berlin Woodworking Company has been given the contract of finishing the interior of the post office, and have sub-let contracts for parts of the work to Messrs. Falconer and McDonald. The contract price for the completion of the work is about $15,000.

Saskatoon, Sask.—Mr. B. Lancaster of this city, has the contract for additions and alterations at the Empire Hotel, the work costing in the neighborhood of $80,000.

Port Arthur, Ont.—Messrs. John S. Metcalf & Co., of Montreal and Chicago, have received the contract from the Grand Trunk Pacific to erect another 2,500,000 bushel unit to their elevator on Mission Island. Estimated cost, $500,000,

Vancouver, B.C.—Messrs. J. McDiarmid & Co., 138 Portage avenue, Winnipeg, have received the contract for the erection of a six to ten-story warehouse and cold storage plant on Water street for Messrs. Swift & Co. Estimated cost, $300,000.

Victoria, B.C.—The Westholme Lumber Company have received the contract for the Sooke Lake Waterworks, their price being $1,169,720. This was the lowest tender of the nine that were received for the complete work, including a reinforced concrete pipe between Sooke Lake and Humpback reservoir, and a riveted steel pressure pipe line from Humpback reservoir to the city.

Victoria, B.C.—Mr. Thomas Stedham has the contract for the repair of Smith's Hill reservoir, the contract price being $19,600. The contract calls for making water-tight the big receptacle and the construction of a wall ten feet in height through the centre of the basin, with necessary alterations to the intake and outlet pipes.

Windsor, Ont.—The contract for the construction of the new sewer on Tuscarrora street and Gladstone avenue has been awarded to Mr. Thomas Chick.

RAILWAYS—STEAM AND ELECTRIC.

Guelph, Ont.—The profits of the Guelph Street Railway for 1911 amounted to $7,449.

New Westminster, B.C.—Two new boats are under construction for the Grand Trunk Pacific Railway. These boats will be 140 feet long by 34 feet wide, stern wheelers, with a carrying capacity of 250 tons each. Two barges will be built in addition, and each boat, with a barge in tow, will have a carrying capacity of 500 tons of cargo each trip. The engines for these boats have been removed from the "Conveyer" and "Operator," which have been operated on the Skeena River for the past two years, and will give these boats a speed of fifteen miles an hour.

Ottawa, Ont.—At the operating sittings of the Board of Railway Commissioners, to be held in Ottawa on Tuesday, February 6th, 1912, commencing at ten o'clock in the forenoon, the board will consider the matter of requiring all railway companies subject to its jurisdiction to equip their locomotive engines with dump ash pans, or other appliance, to avoid the necessity of enginemen or others going underneath to clean the same.

Montreal, P.Q.—From 1,000 to 1,500 more miles of telephone train despatching circuits will be put into operation by the Canadian Pacific Railway during the coming year. The system of despatching trains by telephone has proved entirely satisfactory. The C.P.R. now has 1,000 miles of telephone wires in use for train despatching and is the second largest user of this method of despatching trains in the world. The additions which will be made during 1912 will make it the largest. Practically all the main lines in the eastern division of the C.P.R., with the exception of the line to Ottawa, are using this method to-day. By means of the system it is possible to get telephonic connection with any train on the line. Every train carries a telephone and a long pole, which may be hooked to the wire along tthe right of way whenever the need arises.

Thamesville, Ont.—Locomotive No. 1890, of the Mogul type, on a westbound Wabash freight exploded. The explosion was terrific, awakening the whole town and burning pieces of debris were blown blocks from the tracks. The whole body of the engine was blown several yards ahead of the lower part of the engine and turned completely upside down, parts of the car being found yards away. The exact cause of the explosion is not known.

Winnipeg, Man.—The Canadian Northern Railway have hauled wheat in large quantities to their elevators at Port Arthur and also to the Atlantic seaports. The total number of bushels of wheat marketed at points along the company's lines this year is 38,750,000 bushels, against that of twenty-four million bushels marketed last year for the same period, which shows an increase of fourteen million bushels. The Canadian Northern Railway have in store in their interior elevators eight million bushels of grain, while last year, for the same period, they only had three and three-quarter million bushels.

LIGHT, HEAT AND POWER.

Brockville, Ont.—To encourage the erection of uniform cluster lamps for street lighting, the board of light commissioners have decided to allow a special discount of 25 per cent. off present net current rates (10c. per K. W. H. for current used in same and for window lighting when said window lights are used only when lamp standards are used and connected with same meter.

Dundas, Ont.—A defective insulator in the hydro-electric station at this point, was indirectly the cause of the death of one workman and serious injury to another. During the light load period of January 1st repairs were undertaken with the above mentioned results.

Guelph, Ont.—According to the new electrical rates customers will have to pay a minimum charge of $5. It is the Commissioner's intention to keep the minimum charge in Guelph at $5 for the present at least, the reduction over the old basis will be from twenty-two and one-half to twenty-five per cent. Some customers will have a greater reduction on account of being larger consumers. The rates they are adopting at the beginning of 1912 are a fraction lower than any other city outside of Toronto and London, Ont. The net charge has been nine cents; the average price now will be between six and seven cents. The churches will have a reduction of from nine cents to six cents, the hotels will average a little over six cents, the stores and houses between six cents and seven cents.

Hamilton, Ont.—A report states that the Mackenzie and Mann interests will take over the Dominion Power and Transmission Company and all its holdings, including the Hamilton Street Railway, the Brantford and Hamilton Railway, Grimsby and Beamsville Railway, the Hamilton and Dundas Railway, the Hamilton, Burlington and Oakville Road, and the Cataract Power Company.

Hamilton, Ont.—Needle ice getting in the flumes at the De Cews Falls generating plant of the Dominion Power and Transmission Company caused considerable trouble recently. The city was in darkness one night, all traffic on the street railway and suburban roads being tied up. Hamilton's industrial establishments were helpless, and thousands of people were thrown out of work. Similar trouble last year tied things up for several days, causing heavy loss to the company, manufacturers, and thousands of men.

Port Dalhousie, Ont. — The Maple Leaf Rubber Company, who have been supplying this municipality with light for some time, have come to an agreement with the town authorities whereby the supply will not cease until further negotiations may be undertaken.

St. Thomas, Ont.—The hydro-electric service has been interrupted at intervals of late owing to defective wiring between London and Woodstock. The cause for the interruption, it was thought, could be traced to a broken insulator, which there are some reasons to believe was wilfully smashed on the line wire by a rifle shot.

Victoria, B.C.—A compromise may be reached between the city and the British Columbia Electric Railway Company with regard to the dispute over light and power rates. The city's contention is that the new rates agreed upon should have gone into force when the Jordan River power plant was completed on October 12 last. The company's contention has been that the new rates are not effective until a new ten-thousand horse-power plant has been installed at Jordan River, which will be next September. The company wrote to the city offering to put the new rates in force on March 1. The City Council replied that the threatened legal proceedings will be dropped if the date is made February 1, 1912.

Winnipeg, Man.—An announcement of a big reduction in light and power rates has been made. This matter has been pending since the opening of the new civic power plant and final action was taken by the city council and board of control in joint session. The rates fixed were three and a third cents per kilowatt hour for light, with a ten per cent. discount for cash, which places the price for light at less than three cents per kilowatt hour. The minimum charge per month was fixed at fifty cents, as against one dollar charged previously. The Winnipeg Electric Railway Company's rates have been ten cents per kilowatt hour up to a recent date, when it was lowered to seven and a half cents. Power rates fixed by the city range from a quarter of a cent. to one and a half cents per kilowatt hour. These prices work out on a basis of cost so far below that which was obtained heretofore that the citizens on the whole are highly pleased over the matter.

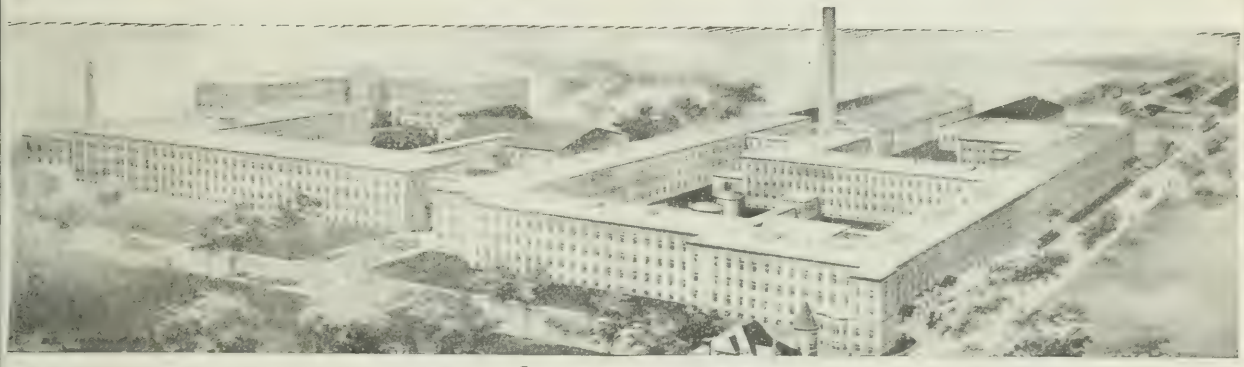
SEWAGE AND WATER.

Merriton, Ont.—The municipal receiver was out of commission one day last week, owing to anchor ice at the intake pipe.

Chatham, Ont.—The Civic Waterworks Department is handing over a surplus of $3,500 to the city after an exceedingly successful year, characterized by decreased cost of maintenance and considerable extensions to the plant.

Sarnia, Ont.—The intake pipe has been found to be broken at a point about 200 feet from shore. A diver discovered that the pipe had been dragged north about twelve feet, so that the connection was completely severed. From appearance the intake had evidently been in that condition for some time, the pipe not having been inspected for the past three years.

Barrett Specification Roofs



Warner Bros. Co., Corset Manufacturers, Bridgeport, Conn. Day & Zimmerman, Engineers, Philadelphia, Pa.

The Most Economical Roof

FOR half a century architects have known that slag and gravel roofs would *often* show marvelous durability.

The Barrett Specification defines the method by which these roofs may be built so that they will *always* show such durability.

It provides for the best materials manufactured, and prescribes the most approved methods of application.

A Barrett Specification Roof will cost less than any other permanent roof, will last upwards of twenty years and will need no painting or coating or care. Such roofs are fire-retardant and take the base rate of insurance.

That is why they are invariably used on large manufacturing plants where the roof areas are great and where, therefore, the unit costs are carefully studied.

Booklet giving the Barrett Specification in full mailed free on request. Address nearest office.

Special Note

We advise incorporating in plans the full wording of The Barrett Specification, in order to avoid any misunderstanding.

If an abbreviated form is desired however the following is suggested:

ROOFING—Shall be a Barrett Specification Roof laid as directed in printed Specification, revised August 15th, 1911, using the materials specified, and subject to the inspection requirement.

The Paterson Manufacturing Co., Limited

Montreal Toronto Winnipeg Vancouver St. John, N.B. Halifax, N.S.

CURRENT NEWS.

Brantford, Ont.—The by-law to raise $85,000 for the improvement of the John H. Stratford Hospital was carried by nearly 500 majority.

Bracebridge, Ont.—The by-law for a loan of $60,000 to the Dominion Linen Mills, Ltd., was defeated.

Brampton, Ont.—The by-law to purchase the Brampton Electric Light franchise was carried by a majority of 140.

Berlin, Ont.—The by-law to raise $100,000 for extensions to the waterworks system was carried by 576 majority. The by-law to raise $10,735 for the deviation of Wilmot raise $125,000 for storm sewers, the vote being 1,269 to raise $10,000 to purchase additional appliances and equipment for the fire department, including a motor truck, was defeated by 163 majority. The by-law to raise $7,400 for meeting the expense incurred in making extensions of the Berlin & Waterloo Street Railway was carried by a majority of 344. The by-law to raise $1,700 for a trunk sewer was carried by a majority of 302.

Barrie, Ont.—The by-law to raise $50,000 for improvements to the Barrie Collegiate Institute was beaten by 581 to 238. The by-law to raise $35,000 for sewers carried by 571 to 269.

Clinton, Ont.—The two by-laws voted on both carried: Hydro-electric by-law, majority 109; good roads by-law, 123 majority.

Edmonton, Alta.—A suggestion has been made to conduct the municipal scavenging department differently than it has been in the past. It will be made a separate department from the medical health officer's department, and conducted along different lines. The reason given for such a change was that the scavenging work is not being properly done. Several instances are recorded where refuse is not cleaned up, and also in the backyards of several citizens where the refuse is not burned, thus becoming a menace to the public.

Edmonton, Alta.—A company is forming to operate certain gravel pits adjoining the city. The company's officers are in communication with the commissioners asking if the city would allow the company running rights over the street railway tracks to the company's stations and depots for the carriage of freight; if the city would allow running rights over the railway for the supply of gravel and coal; and if the city would allow the company the privilege of the tracks for delivery of coal and gravel at special points within the city. The letter was written to enable the promoters to arrive at a correct estimate of the value of the proposal which they have in hand at the present time.

Edmonton, Alta.—The municipal telephone department in November netted a surplus. The revenue was $7,129.46, and the expenditure $5,722.38, thus showing a surplus of $1,407.08 for the month. The grand surplus for the year amounted to $32,219.01. The capital receipts, including balance on hand, amounted to $8,137.31. The capital expenditure was $4,448.42, against $1,705.65 in 1910.

Fort William, Ont.—The committee controlling the public utilities, consisting of electric light, water and telephones, have a surplus of $10,105 on the yearly operation of the combination. The gain of the electric light system amounts to $12,270.21, the water department $1,000, and the telephone system shows a deficit of $3,165.21.

Guelph, Ont.—The by-law to erect a new fire hall, equipped with auto apparatus, was defeated by 589 votes. The by-law to further extend the street railway in St. Patrick's Ward was carried by 623 majority. The by-law to place the sewerage and public works under a commission, carried.

Hamilton, Ont.—The Steel Company of Canada intend to open two new hearth furnaces of fifty tons capacity a day, also a blooming mill, a continuous billet mill and a combination rod and bar mill. They will be in operation by next October, employing a thousand additional skilled workers. Later on it is intended to erect factories for finishing wire goods. The extension will cost $2,000,000.

Hamilton, Ont.—By-laws to raise $833,000 were submitted, and the electors carried all but one, that to purchase the Oaklands property on the north shore of the bay, at a cost of $40,000. They authorized an expenditure of $793,000 as follows:—Waterworks extension, $650,000; east end park, $60,000; central fire station, $65,000; Gore Park convenience, $14,000. The vote was:—Waterworks, 3,705 for, 1,169 against; east end park, 2,353 for, 1,965 against; fire station, 2,903 for, 1,468 against; Gore Park, 2,922 for, 1,608 against.

Ingersoll, Ont.—The $125,000 by-law for the purchase of the waterworks was carried by a majority of 48.

Lethbridge, Alta.—The commission sitting at Lethbridge to arbitrate on the recent differences in mining matters between the United Mine Workers and the Western Coal Operators Association, have forwarded their report to Ottawa. The question of wages occupied a prominent part in the proceedings, and the following has been recommended to apply to Maple Leaf Coal Company, Bellevue, Alta.:—

	Per Day
Minimum wage	$3.00
In Parallel airway old mine	6.35
In Angle Chute old mine	3.50
Parallel airway	5.90
Pillar work (per cubic yard)	0.43

London, Ont.—The ratepayers voted in favor of all but one of four by-laws. The by-law to be defeated was one to raise $125,000 for storm sewers, the vote being 1,269 to 2,272. A by-law to bonus the North Midland Railway for a radial terminal station to the extent of $65,000, was carried by a vote of 2,345 to 1,357. One to appropriate $20,000 toward a bridge from South to West London by 2,113 to 1,596, and a third, to spend $50,000 on a garbage system, by 1,883 to 1,816.

Montreal, P.Q.—A shack, in which was stored the civic dynamite, was destroyed, when the contents exploded in the early morning of December 31st last, a watchman narrowly escaped death. He was struck and knocked down by a piece of the flying timber and badly cut and bruised. Many windows in the immediate neighborhood (Rosemount) were smashed, and the explosion was heard in all sections of the city.

Montreal, P.Q.—The legislation committee of the city council has decided to petition the Provincial Government for power to grant franchises to automobile omnibus companies, with a view of relieving the present congestion on the street railway cars.

Ottawa, Ont.—Work on the new civic incinerator has been started. Many difficulties have had to be faced in this project, among which were legal differences regarding the transfer of the site.

Owen Sound, Ont.—The by-law to loan $20,000 to a nut and bolt factory was carried by a large majority, as were also the hydro-electric and gas extension by-laws.

Ottawa, Ont.—The by-law submitted to the ratepayers to vote a sum of money to obtain a water supply from McGregor Lake, was defeated, very few votes being recorded in its favor.

Port Stanley, Ont.—The plans of the $600,000 sea-wall which is to be constructed by the Dominion Government at the east side of Port Stanley harbor, which was decided upon by the Laurier Government at the last session of parliament, has been approved by the new Conservative Government, and the work will be proceeded with, it is expected, during the year. It is reported that the contract will go to a construction company now being organized by Mr. A. E. Ponsford.

Quebec, P.Q.—Dr. J. A. Beaudry, chief inspector, Province of Quebec, has gone to the provincial capital to be at the disposal of the authorities should need arise from the present alleged smallpox epidemic. Dr. Beaudry is considered an expert in smallpox diagnosis.

Renfrew, Ont.—A by-law to pay $60,000 for the further development of the power plant carried.

Ridgetown, Ont.—The canning factory by-law was carried in this municipality by a majority of 313.

Sarnia, Ont.—The Mueller Brass Company bonus by-law was carried by 1,407 for and 96 against. When the company have invested $100,000 in buildings, etc., and employ 100 men, they will receive a bonus of $20,000 and another $10,000 when 50 more men are employed.

Stratford, Ont.—The by-law to loan the Jennewitz Co. $10,000 to assist in starting manufacture of piano accessories, was defeated.

St. Thomas, Ont.—The by-law to raise $10,000 for an Isolation Hospital carried by 400 majority. The plebiscite on extending the Citizens' Street Railway to Port Stanley was given an adverse vote of 750.

ELECTRIC MOTOR DRIVE

FOR GRAIN ELEVATORS

In the illustration is a row of 100 h.p. motors driving the receiving and shipping legs in the new G.T.P. elevator at Fort William. There are 37 of these motors in the elevator, ranging from 5 h.p. to 100 h.p., and aggregating 2,500 h.p. Individual motor drives are used, making impossible any serious disarrangement.

P.O. Box 563.

Full Particulars and Estimates Furnished.

Toronto, Ont.—An old twenty-four-inch water main burst just before midnight, New Year's eve. The break occurred between two railway tracks on the esplanade in the vicinity of John Street. In a few moments ten tracks were covered with water so that they could be counted only by means of the cars on the rails. The water spread from the Union Station to a quarter of a mile west. The workmen of the water service could not get to the main, so that the only way of fixing it was to shut off the main near the pumping station. The main was the first one laid in Toronto, and it was put in thirty-nine years ago. It was sunk ten feet under the tracks. At the time the break took place the pressure was 100 pounds to the square inch.

Toronto, Ont.—The ratepayers have voted to spend $2,200,000 on extensions of the hydro-electric scheme; $1,783,333 on an extension of Bloor street, and $139,488 on car line extensions.

Vancouver, B.C.—It is recognized that the Fraser River will supply all the waterfront that will be required by the expansion of Vancouver and the greater city that lies between Burrard Inlet and the Fraser. But before permanent improvements are carried out, it is the opinion of Mr. Louis Coste, civil engineer of Ottawa, who is on the coast on a mission for the Dominion Government, that a commission of engineers should be appointed to decide the best course of action. Tenders are being called for the construction of a jetty at the mouth of the Fraser. This is the recommendation of a prominent engineer, who stated that with this jetty, perhaps two, the river would clear its own channel and keep it clear. Mr. Coste expresses the opinion that the construction of this jetty is premature, and thinks the best results would be obtained by a commission of three experts, for the task is too big to leave to one man

Winnipeg, Man.—The fire commissioner states that 100 fires during the past year in Winnipeg were due to defective chimneys, the fault of knowingly careless workmen or contractors. His contention in one case was supported by the city building inspector, who said that a new house which was almost destroyed by fire had no mortar in the layers of bricks in the chimney against the woodwork.

Welland, Ont.—The ratepayers decided to adopt the hydro-electric by-law by a majority of. 334. The settling basin measure was defeated.

Winnipeg, Man.—The committee of the Board of Trade investigating the municipal telephone rates have started their task. The investigation will cover a wide area, and, will cover the whole management of the telephone system since it was taken over by the Manitoba Government. The question of telephones is causing considerable trouble throughout the province, owing partly to the recent deficit in the operation of the system.

The following is a list of Ontario municipalities which voted for the hydro-electric by-laws:—

Municipality—	Majority for
Ailsa Craig	85
Blyth	52
Brampton	140
Brussels	Large
Caledonia	180
Clinton	109
Cornwall	Large
Exeter	Large
Goderich	Large
Hagersville	Large
Hastings	71
Hensall	88
Kincardine	286
Kingston	Large
Lakefield	201
Listowel	Large
Lucan	Large
Owen Sound	Large
Paisley	Large
Paris	Large
Peterboro'	1,315
Prescott	154
Richmond Hill	118
Southampton	186
Tillsonburg	Large
Thornbury	140
Wingham	Very large
Wroxeter	Very large

The receivership for Allis-Chalmers Company, Milwaukee, U.S., will be of a friendly character and is one of the preliminary steps necessary in the reorganization of the company. Meantime the shops at Milwaukee, Chicago, and Cincinnati are running as usual and the operations of the company will not be curtailed. It is understood that $5,000,000 new capital has been provided. This will place that company in a far stronger position than it ever was before, and will enable it to take advantage of the revival of business which is anticipated in the United States at an early date. Allis-Chalmers-Bullock, Limited, of Montreal, is an entirely separate and distinct corporation, and is not in any way affected by the proceedings in connection with the American company. It has not felt adverse conditions similar to those in the United States; but, on the contrary, the shops are full of work and running regular time. The present proceedings will not affect the operations of the Canadian company.

TRADE ENQUIRIES.

The following were among the enquiries relating to Canadian trade received at the office of the High Commissioner for Canada, 17 Victoria Street, London, S.W., during the week ended December 18th, 1911:—

A Swiss firm is desirous of appointing Canadian agents for the sale of pipe-straw hats.

A London firm desire to get into touch with Canadian importers of dressed bath stone.

A firm of brokers and sales agents at Lucknow, India, are open to act for Canadian manufacturers of fancy goods, stationery, leather goods, sugar, provisions, piece goods, etc.

A Toronto firm stated to have a large staff of salesmen are desirous of taking up United Kingdom agencies.

The Canadian agent of an English manufacturer of condiments and essences is desirous of securing the agency for another line which he could work in conjunction.

A Montreal importer desires to obtain the representation of a United Kingdom manufacturer of fancy goods.

A Montreal firm of mechanical engineers stated to have a large connection wish to represent English manufacturers of railway contractors' and general engineering supplies.

A Nova Scotia correspondent desires to interest English financiers in an undeveloped coal area in that province.

A Vancouver firm of stationers, printers and bookbinders would like to get into touch with manufacturers in Great Britain of corduroy and canvas suitable for bookbinding. Samples and quotations required.

A Montreal correspondent enquires for names of miners of China clay in Cornwall.

A correspondent in Canada is desirous of finding a market in Great Britain for slaughter-house offal.

A Vancouver firm are in the market for Irish linen table cloths and similar goods. Quotations required f.o.b. Vancouver and Cape Horn or Tehauntepec.

From the branch for City Trade Enquiries, 73 Basinghall Street, E.C.:—

An Italian importing firm invite quotations from Canadian shippers of hog and beef casings.

A London firm ask to be placed in communication with Canadian manufacturers of wood pulp who are in a position to fill orders for regular shipment.

A North of England company manufacturing a patented safety valve wish to get into touch with some Canadian resident firm possessing an established connection with railways, etc., who would act as their representative.

A manufacturers' agent in Toronto wishes to secure the representation of United Kingdom manufacturers of druggists' sundries, food specialties (such as jams, custards, etc., not already represented) and novelties in photographic lines.

A Toronto manufacturing company ask to be placed in correspondence with United Kingdom producers of picker cuttings from hide stock as used in the manufacture of glue.

An engineering firm in Ottawa desire the addresses of British manufacturers of oil burners for steam boilers.

A Winnipeg firm wish to be placed in communication with manufacturers of linen-lined paper bags for sending sample seeds through the post.

Two Great Needs Filled

Goodyear Sheet Packing for High or Low Pressure
Magnet High-Pressure Gasket Tubing

After months of painstaking experiment we have perfected Sheet Packing and high-pressure *Gasket Tubing* that forever *do away* with the disappointment, trouble and expense caused consumers by the many cheap and worthless grades that have been placed on the market.

Magnet Sheet Packing

Made of the celebrated Magnet compound, this packing is totally *unaffected by heat, oil, liquor (ammonia), alkali, or by expansion or contraction.*

It is suitable for high or low pressure uses, particularly high, because of its heat-resisting properties. It neither becomes hard nor brittle. Retains its tough, elastic efficiency for months.

Magnet Sheet Packing won't *blow out.* It makes a tight joint that stays tight under air, hot or cold water or strain pressure.

Meets every requirement.

No engine room, locomotive, steamboat or machine shop is properly equipped without a roll of this great emergency packing.

GOODYEAR

Magnet High-Pressure Gasket Tubing

Made also from the celebrated Magnet compound. Forms a tight joint no matter how rough the surface may be—and it is

Pressure-Proof

Magnet Gasket Tubing can't blow out. Like Magnet Sheeting, it successfully resists any degree of steam heat and it maintains its elasticity.

Cut to Fit

One of the big advantages of Magnet Gasket Tubing is that it may be cut any length to fit any size manhole or handhole, plate or pipe flange. Cut ends joined together with rubber core, making *continuous gasket.* Put up in convenient boxes with rubber core and tape.

If you need sheet packing or gasket tubing, grasp this opportunity. The Goodyear trade-mark stands for reduced first cost and economy all along the line. It stands for the same quality workmanship that underlies the success of the Goodyear Tire & Rubber Company, Akron, Ohio, one of the best known and most experienced manufacturers of rubber goods in the world.

PUBLIC UTILITY COMPANIES IN BRITISH COLUMBIA.

The British Columbia Electric Railway Company operates in Vancouver and New Westminster, with suburban and interurban lines on the lower mainland. It owns the light and gas franchises in Vancouver and the lighting franchise in New Westminster, also in Victoria, where it has the lighting franchise. It has a power plant on the mainland, another near Victoria, on Vancouver Island, and is the biggest company in the West.

The British Columbia Telephone Company's charter enables it to have systems throughout the province, but its main operations are in Vancouver, Victoria, New Westminster and between these points.

The telephone company has had its own troubles to give an adequate service in Vancouver, which has grown so rapidly. There have been complaints regarding service, and suburban districts have complained also of the rates. There is a suggestion to have the provincial government take over the telephone system. The latest public body to recommend this is the combined board of trade of Richmond and Point Grey. The statement was made at the meeting that while the rates might be about the same, the service would be better. The telephone company has had to increase its rates for business telephones in Vancouver and Victoria, and this will bring further criticism.

The difficulties that beset the telephone company are infinitesimal compared with those of the British Columbia Electric Railway Company. The Point Grey by-law, giving the company power to operate in Point Grey, has been dismissed in the courts, and all construction and service has been discontinued in that suburb of Vancouver. The company has stood strictly upon its rights, and naturally will have nothing to do with any compromise proposals.

The City Council unanimously agreed to see if the company's franchise in Nanaimo cannot be cancelled, because of the persistent ignoring of requests for a better service. Certain it is that in many points which tend to the comfort and convenience of the people, the company has been deficient. In some cases passengers have to wait fifteen minutes for connecting cars. After the action of the city this week, to seek annulment of the franchise, the company, which by the use of passes keeps criticism out of the papers, gave figures to show that the number of cars used were as large in proportion as on street railway systems in other cities. It based its calculations on the population of Vancouver proper, allowing so many cars to these people. The real facts are that 30,000 to 40,000 more people are served, and Vancouver proper cannot be considered by itself, for all the people in the districts immediately adjoining work in the city and come and go morning and evening.

It is reasonable to suppose that because conditions are such that the company cannot adequately cope at present with the situation, the government will not allow cancellation of the franchise. The company has at least been sincere in its general attempts, and if it has been overwhelmed by circumstances, the fault is not altogether its own. All these inconveniences are incidents of sudden and enormous growth in the city.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA.

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from The Canadian Engineer for small fee.

CIRCULAR NO. 73.

FENDERS OR WHEEL GUARDS.

The Board of Railway Commissioners ask that all electric railways subject to the Board's jurisdiction file, within sixty days from the date of this circular, plans showing the system of fenders or wheel guards in use on their equipment.

15595—December 12—Authorizing Government of Province of Saskatchewan to construct highway over C.P.R. in S.W. ¼ of Sec. 30, Twp. 15, R. 13, west 3rd Meridian.

15596—December 9—Suspending Wabash Railroad Co.'s Tariff 686, re "Baggage of Excess Size," until parties can be heard.

15597—December 12—Approving location of C.P.R. station at Lydiatt, Man.

15598-99—December 12—Approving revised location of Dominion Atlantic Ry. (under C.P.R. lease) from west side of St. George St., Annapolis, N.S., to west side of Allen's Creek, a distance of 2,790.5 feet, and authorizing reconstruction of Allen Creek bridge.

15600—December 14—Approving plans of C.N.O. Ry. for undercrossing of C.P.R. at Smith's Falls.

15601—December 14—Authorizing Esquimalt & Nanaimo Railway to cross with its Cowichan Lake Branch two highways in British Columbia.

15602—December 13—Authorizing C.N. Pacific Ry. to use crossing of C.P.R. Mission Branch for construction purposes only until 29th February, 1912, pending installation of interlocking plant.

15603—December 18—Approving revised location of C.N.O. Rly. (Montreal-Port Arthur) through Twps. of Bristol, Clarendon and Litchfield, in County of Pontiac, Que., mileage 162 to 176, from Montreal.

15604—December 19—Directing C.N.O. Ry. to install improved type of electric bell at crossing near Brighton, Ontario.

15605—December 16—Authorizing C.N.O. Ry. to construct bridge over Blende River, at mileage 23.96, east of Port Arthur, Ont.

15606-07—December 18—15608—December 19—Authorizing C.N.R. to cross with its Maryfield Line public road between Secs. 12 and 11, Twp. 5, R. 8, west 2nd Meridian, and with its Swift Current Line 7 highways in Saskatchewan, and with its Swift Current Line three highways in Saskatchewan.

15609—December 15—Approving location of Alberta Central Railway Co. from a point on its main line 135.58 miles west of Red Deer to Big Horn Range Coal Fields, mileage 0 to 28.

15610—December 19—Authorizing G.T.P. Ry. to cross highway at mileage 197.2, Range 6, Cassiar District, British Columbia.

15611—December 18—Approving plans of G.T.R. for station at Stevensville, 19th District, Southern Division.

15612—December 19—Authorizing C.P.R. to open for carriage of traffic its Swift Current to Brooks Branch from mileage 0 to 33.

15613—December 19—Authorizing C.P.R. to operate until June 30, 1912, its Manitou Lake Branch from a point on its Pheasant Hills Branch, being from mileage 0 to 27.8, between Wilkie and Cut Knife, Saskatchewan.

15614—December 16—Approving revised location of C.P.R. Lauder Extension between mileage 32.28 and 54.63, Saskatchewan.

15615—December 16—Authorizing C.P.R. to cross with its Wilkie Northwesterly Branch (formerly known as Manitou Lake Branch), 14 highways between mileage 13.90 and 25.78, Saskatchewan.

15616—December 18—Authorizing C.N.R. to cross with its Maryfield Line 16 highways in Saskatchewan.

15617—December 13—Approving overhead clearances of West Canadian Collieries, Ltd., for siding of C.P.R. at Bellevue, Alta.

15618—December 20—Approving location of C.N.R. Crosse Isle Extension, mileage 4.33 to 25.68, west P.M., Manitoba.

15619—December 19—Authorizing G.T.P. Ry. to cross highway at mileage 204.5, Range 6, Cassiar Dist., British Columbia.

15620—December 19—Authorizing G.T.R. to construct spur for joint use with C.N.O. Ry. on Don Esplanade, Toronto, Ont.

15621—December 12—Authorizing C.N.R. to construct spur line to Hospital for Insane at North Battleford, Saskatchewan.

15622—December 13—Authorizing Dominion Atlantic Ry. to construct spur from a point on its Cornwallis Valley Branch to Government wharf, at Canning, N.S.

15623—December 15—15624—December 13—15625—December 9—Authorizing C.P.R. to construct spurs for Alberta Consolidated Coal Co., Ltd., near Elcan Ballast Pit, Alta., and for Messrs. Anderson & Rosenroll at mileage 59.2, on Wetaskiwin Subdivision, near Ohaton, Alta., and for Messrs. Wiens & Reimer at Foam Lake, Saskatchewan.

15626—December 14—Authorizing Esquimalt & Nanaimo Railway to construct spur on Vancouver Island, at mileage 47.5 (from Victoria) to near village of Croftonat, mileage 0.78 in Chemainus District, British Columbia.

15627—December 18—Recommending to the Governor-in-Council for sanction lease by C.P.R., or Alberta Railway & Irrigation Co.

15628—December 15—Approving location of Alberta Central Ry. from mileage 100 to 140, west of Red Deer, Alberta.

15629—December 20—Authorizing G.T.P. Ry. to operate trains over overhead crossing of C.N.R., in Sec. 14, Twp. 53, R. 24, W. 4 M.

15630—December 12—Extending until February 1st, 1912, time for installation of power brakes by C.P.R. on electric cars.

15631—December 18—15632—December 15—Authorizing C.P.R. to construct spur for A. E. Burns, near Henry Avenue, city of Winnipeg, Manitoba, and spur for Rock Springs Sootless Coal Co., Ltd., near Elcan Ballast Pit Spur, Alberta.

15634—December 20—Approving location of Esquimalt & Nanaimo Ry. from Black Creek to near Duncan's Bay, on Vancouver Island.

15635—November 21—Directing that Supplement to Canadian Classification No. 15, be issued reducing carload rating of Macaroni, Spaghetti and Vermicelli, from 4th to 5th class to become effective not later than January 15th, 1912. Application Transportation Bureau of Montreal Board of Trade, on behalf of the Montreal Wholesale Grocers' Guild.

15633—December 16—Authorizing C.N.O. Ry. to use for construction purposes only crossing of C.P.R. at Chaudiere Jct., near Ottawa, until June 1st, 1912, pending completion interlocker.

15636-37—December 13—Directing that Wabash Railroad (G.T.R.) install gates at Manitoba Street, St. Thomas, Ontario, before 1st May, 1912, 20 per cent. from Railway Grade Crossing Fund, also G.T.R. to install electric bell at St. George St., Chatham, Ont., before 1st February, 1912, 20 per cent. from Railway Grade Crossing Fund.

15638—December 16—Extending until June 1st, 1912, time for installation of interlocking plant at crossing by C.N.O. Ry., of C.P.R. and G.T.R. near Ottawa, Ontario.

Have You a Want ?

If you have a position vacant, or if you want a position, an advertisement in The Canadian Engineer will do the trick. Two cents per word.

An Engineering Weekly

THE ULTRA-VIOLET RAYS.

The engineering profession at large, and persons who have had no occasion to investigate the subject, appear to regard the rays of light as the only manifestation of the disturbance in the ether which causes the human eye to perceive and distinguish colors; this is not correct, as of late many other varieties of "rays" have been isolated and found to possess qualities vastly different from light rays. Among the latter to be isolated and examined are the ultra violet rays which have their sphere of motion at the extreme violet end of the spectrum.

The rays which are commonly called "light" are composite, being formed of seven rays which move with a sufficient relaxation to affect the optic nerves; these seven are red, orange, yellow, green, blue, indigo and violet.

The first important manifestation of these auxiliary rays were noticed by Professor Roentgen. This gentleman, not understanding their characteristics, gave them the now familiar name of X rays. As is well known, the feature of these rays which causes them to be so useful, is that of piercing many substances opaque to ordinary light rays. The X ray, however, moves at such an astounding speed as to be entirely unnoticed by the optic nerves, and in order to retard this enormous speed a screen of basium platinocyanide is placed between the object pierced and the human eye. These rays, in common with ordinary light, cast well defined shadows.

Prof. Roentgen, in his original memoir on "A New Kind of Rays," remarks that a kind of relationship between the X rays and light rays appears to exist; at least the formation of shadows, florescence, and the production of chemical action point in this direction. It has been known for some years that, in addition to the transverse vibrations which account for the phenomena of light, it appears that longitudinal vibrations may exist in the ether, and, according to the view of certain physicists, must exist. It is granted that their existence has not yet been made clear, and their properties are not experimentally demonstrated. It is a question if the new rays should not be ascribed to longitudinal waves in the ether.

The next discovery of importance in this direction was made by the Curies when they reached the source of certain radiations in discovering and isolating radium. Although these persons are justly credited with discovering and isolating the salts of radium, they cannot be credited with the prior discovery of the radiations. This honor must go to Prof. Henri Becquerel, who was following up the work of Prof. Roentgen when he became aware, accidentally, that certain inorganic substances, supposedly uranium, were capable of evolving emanations which conducted themselves in a degree, similar to the X rays. Subsequent investigation by Prof. and Madame Curie disclosed the fact that these emanations proceeded from certain impurities previously unknown, which were regarded as a residue in the distillation processes to which the uranium and salts of that element were subjected. These impurities were later found to be three undiscovered elements, and were given the name of polonium, actinium, and radium. Of these radium is by far the most active.

Professor and Madame Curie have determined the atomic weight of radium and find it to be 225. Radium, although considered an element, has not, up to recently, been isolated in the elementary condition; all experiments are carried out with the chloride or bromide.

The radiations from radium appear to possess the property of disintegrating organic tissue. A small quantity of radium introduced beneath the skin of a mouse near the spinal column, produced speedy death from paralysis. However, although this action is known, it is safe to say that no definite concise understanding of the destructive or medicinial properties of this element have been acquired.

Fig. 1.

Through the development of the mercury vapor lamp it was found possible to produce ultra-violet rays in such a form that they could be experimented with. The lamp which is generally used in a modification of the Copper Hewitt lamp illustrated in Fig. 1. In this apparatus a small quantity of mercury is confined in a glass tube, which is exhausted of air to a considerable extent. Metal electrodes protrude at the extremities, and when the current is led to the lamp the tube is tilted, allowing the mercury to strike an arc, the heat and flash which follows vaporizes the mercury or a portion of it. From the mercury in the vaporous condition come the ultra violet rays, so deadly to bacteriological and low forms of organic life.

The light is deficient in the longer wave lengths, or red. The lack of the longer wave lengths results in an unpleasant distortion of color. The ordinary glass tube allows the blue and violet rays to pass, but is entirely absorbent of the extreme violet (ultra violet) rays. To bring these rays outside, the tube must be constructed of quartz.

To construct a piece of physical apparatus of fused quartz is an extremely difficult operation, owing primarily to the enormous heat necessary—2,000° C. (3630° F.)—and the difficulty of procuring a substance that will manufacture into a suitable crucible.

Quartz is found in nature in the crystalline and amorphous conditions, the former variety being known as rock crystal and quartz sand, and the latter is found as opals and other precious stones. On a piece of rock crystal being heated in an open flame it cracks, and when the fragments are melted in the electric furnace a compact amorphous mass is produced which is absolutely insensitive to temperature influences and shows other properties entirely different from rock crystal.

In 1903 Dr. J. Frank Bottomley commenced in a small experimental works erected at Wallsend, near Newcastle-on-Tyne, Scotland, a series of investigations with the object of developing a method suitable for the manufacture of large size silica apparatus. In spite of the many difficulties encountered in this connection, the experiments after three years were sufficiently advanced to commence working on a commercial basis.

KROMAYER LAMP WITH QUARTZ EXTENSION

A ROENTGEN TUBE

QUARTZ BLOCKS AND TUBES FOR APPLYING ULTRAVIOLET RAYS, WITH PRESSURE, TO VARIOUS PARTS OF THE BODY

As it was intended to obtain a relatively cheap product, a raw material less expensive than rock crystal had to be looked for, and a very pure form of silver sand containing over 99½ per cent. of silica was used.

Electric arcs as well as various forms of resistance furnaces were used in connection with these experiments, but the arc method was found not to be practical on account of the difficulty of regulating the temperature, and the risk of the material being contaminated by fragments expelled from the electrodes. Far more satisfactory results were obtained with resistance furnaces using carbon or graphite as resistance material.

Another difficulty is due to the silica volatizing readily at temperatures a little above the melting point. The difficulty of finding a material sufficiently refractory to serve as the containing vessel, while being chemically inactive in regard to silica, was overcome by allowing the sand itself to form its own containing vessel, which method shows the additional advantage of providing an excellent heat insulating material for the lagging of the furnace. As the surface of the silica farthest from the heating resistance is not thoroughly fused, it should be subjected wherever necessary to a subsequent glazing process. As silica, even at very high temperatures, never becomes really fluid, but attains a consistency like that of tar, it cannot be made transparent. However, in this plastic condition the material is capable of being worked into shape either by blowing or by mechanical pressure. It is, for instance, quite possible to draw a length 60 feet or more of ¾-inch tubing. At the works of the Thermal Syndicate, Wallsend, where the Bottomley process is used, fusions of over 70 pounds can be made, and worked into shape, and it is hoped to increase this considerably.

The most valuable feature of these goods is their remarkable insensitiveness to temperature changes, which even allows iron ore platinum to be sealed into quartz crucibles without the latter losing their shape, their transparency to the ultra violet rays, and their insulating properties, which, though decreasing somewhat with rising temperatures, is even at the temperature of electrical furnaces quite sufficient to make the quartz an electric insulator. This feature is the more welcome, as most oxides used in industry will become conductive to electricity at high temperatures. Quartz is therefore an extremely suitable material for making electric radiators. As quartz tubes are fairly pervious to heat rays, they can, in fact, be used also for the transmission of heat. For a similar reason quartz plates are extremely practical as refractory protective mantles, undergoing a relatively immaterial heating even on being radiated upon intensely.

It would be a difficult task to name the discoverer of the ultra violet rays, but should one be inclined to search out the names of the responsible parties, certain it is that the name of Prof. Niels R. Finsen, of Copenhagen, Denmark, would occupy a prominent position on the list; in fact to that gentleman must go the honor of the pioneer work in the treatment of disease by photo-therapeutics. Prof. Finsen proved that the therapeutic properties of light in the treatment of bacterial diseases of the skin, especially lupus vulgaris, or tuberculosis of the skin, was due chiefly to two properties of the light employed, the violet and ultra violet rays; also their power to penetrate the skin and their destructive action on bacteria.

In Finsen's apparatus, the radiation from an arc lamp was filtered through water, (pure water is a conductor of the ultra violet rays) which absorbs most of the ultra red, or "heat," rays, and was concentrated upon the skin by lenses of quartz (which does not, like glass, absorb much of the ultra violet radiation, and which aids in absorbing the ultra red rays). The Finsen lamp, for the use of physicians in private practice, consists of a 20-ampere direct-current arc lamp, a "concentrator" and a "compressor." The apparatus is so mounted on an iron stand that it can be turned in any direction. The concentrator is a wide metal tube, containing a number of quartz lenses, through which a current of

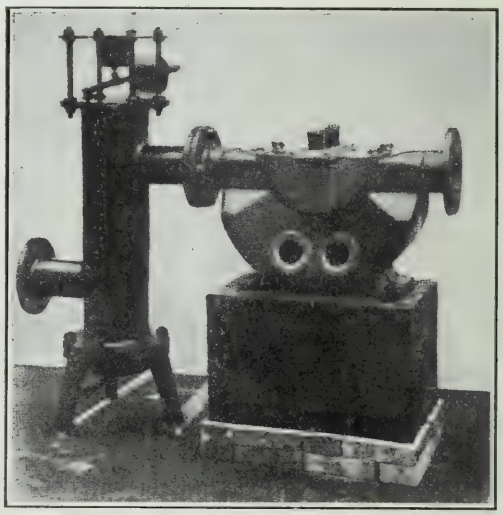

Fig. 2

cold water flows continuously. The compressor is attached to the end of the concentrator and consists of a short brass cylinder, closed at each end with a plate of quartz and filled with the circulating cold water. The terminal quartz plate is pressed against the diseased portion of the skin, which is cooled by the stream of cold water so thoroughly that a very concentrated beam of light, possessing great heating power, can be employed without danger. A still more important function of the compressor is to drive the blood from the skin and thus to make the skin more permeable by the rays. The treatment is applied for at least 45 minutes at a time. The management of the apparatus is not easy, but the method provides a sure cure for lupus and leaves no visible scars. In Copenhagen a great institution, the Finsen Institute, has been established, which receives from the Danish government an annual subsidy of 25,000 crowns (about

$6,700) in return for the free treatment of poor lupus patients.

Within the last few years many arc lamps with metallic electrodes have been invented, which emit a far larger proportion of violet and ultra violet rays than the ordinary carbon arc lamp produces, chief among which is the mercury vapor lamp.

The Kromayer lamp, which is a modification of the Couper-Hewitt lamp and finds considerable employment in light treatment of disease, contains a tube of fused quartz, two-thirds of an inch in diameter, having the form of an inverted V. The air is completely removed from the tube, the ends of which form mercury cups, which constitute the electrodes and are connected to the lighting wires. This luminous tube is inclosed in a globe, which is also made of fused quartz, and the globe is inclosed in a water-tight case of nickled brass, provided with a quartz window, which can be pressed directly against the skin of the patient. The

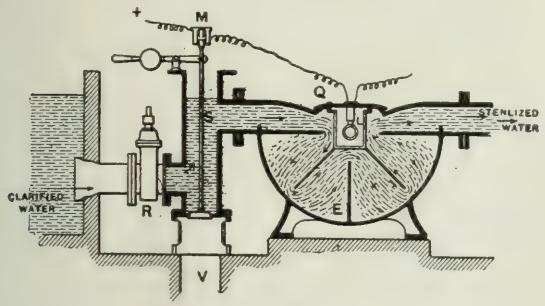

Fig. 3.

space between the quartz globe and its metal case is filled with cold water, which enters continuously through a tube at the bottom of the case and flows out through a tube at the top. The lamp is ignited by tipping it and thus causing a thin stream of mercury to flow along the tube and establish connection between the electrodes. When the lamp is righted and the thread of mercury is broken a powerful luminous arc is formed in the mercury vapor which fills the tube. Local treatment, with or without pressure, can be applied very conveniently with this lamp, but great care must be taken to avoid burning the skin. This treatment is efficacious in all forms of eczema, carbuncles and ulcers of the legs and various parts of the skin and mucous membranes, but especially in "wet" eczema and in circular baldness. Treatment with pressure is employed especially in lupus and burns.

When science had demonstrated her ability to cope with the diseases of men through these mystic rays, mankind in turn bethought himself of using this agency for the purification of his water supplies. The first serious attempt at this appears to have taken place at Marsailles, France. A description of the apparatus used and some details were given in the pages of this journal in the issue of July 13th, 1911, page 47. However, some further details will be of interest at present.

In order to find the best solution of the problem, the municipal council of Marsailles organized a concourse of sterilizing apparatus. Such a plant was required to deliver 200 cubic metres (261.5 cubic yards) of water per 24 hours, and was to be run continuously for one month. The inspection committee included some of the leading specialists in hygiene, mining and civil engineers, and professors of universities. The results of the tests showed that the ultra-violet-ray process was undoubtedly the best for municipal use, as it has none of the defects mentioned below. It uses a small amount of current, and this has now been lowered in the new apparatus. Neither taste nor smell is given to the water, and the sterilizing is very effective. At the same time the process is easy to carry out and the apparatus needs but little attention. The first cost of the plant is low, and it occupies but a small space.

There seems to be a great future in store for the new method, seeing that it has none of the drawbacks which are found with the other processes when it comes to using it on a large scale.

In the sand-filtering method, for instance, the filters occupy a large surface of the plant, and when not properly operated the results are very imperfect. Besides, the first cost of installing the filtering plant is high. Chemical products added to the water for sterilizing have the disadvantage of giving a bad taste to the water, and the method is not much favored for that reason. One of the best methods, to recent date, for municipal plants has been the ozone process, it has been used in some large cities. However, it gives a certain taste to the water which disappears but slowly, and on the other hand there must be a great care taken in the ozone production in order to avoid forming any nitrogenous products, which would vitiate the water. Hence the process is somewhat difficult to carry out, or at least needs great care and attention.

The ultra violet ray apparatus was used in connection with a Puech-Chabal filter in order to act upon clear water, and this was necessary from the fact that the Duvance water is very heavily charged with impurities which render it turbid. After leaving the filter it passes at a continuous rate through the ultra violet ray apparatus.

Fig. 2 shows the appearance of the Marseilles apparatus and Fig. 3 the sectional view. In the former apparatus, the lamps were placed above the surface of the water upon floats, so that all of the radiation from the lamp could not be used, and in fact there was only one-third of the rays actually employed for the sterilizing. A means was sought of utilizing greater proportion of the rays without changing the manner of working the arc. Ii is recognized that the working of the lamp depends essentially upon the temperature of the electrodes and the luminous tube, so that if we cool the lamp too much we will not obtain the same yield in ultra violet rays as before, and to reach the same yield, the current must be considerably increased. For instance, if we immerse the quartz lamp in the water itself, according to Messrs. Courmont and Nogier's method, we are obliged to double the current in order to obtain the same yield as in air.

A great improvement is obtained by the Marseilles apparatus in this respect, as it allows of utilizing more than three-quarters of the rays given by the lamp, and here the lamp burns in air at its best conditions of working, and immersing it in the water is avoided. The lamp is placed in a rectangular case whose three sides lying parallel to the lamp tube are formed of quartz plate. The tight box Q containing the lamp L is placed in a semi-circular apparatus having five partitions in the inside. The water is taken from a tank of filtered water and passes through a gate valve and a cylinder chamber S, then entering the main tank E. It follows around the path which the arrows indicate, and in this way it is exposed for some time to the action of the ultra violet rays, so that we have a powerful sterilizing effect. It is found best in practice to use an automatic valve at the water inlet and it operates in the chamber S. A valve in the lower part of the chamber is normally closed and is held up in this position by an electro-magnet M which attracts an armature mounted on the end of the valve rod. A counterweight is used to give the proper adjustment of the weight. The electro-magnet is connected in series with the lamp, so that when current passes in the lamp circuit the magnet acts and the valve is held closed. Should the current fall or the lamp break, the magnet allows the valve to

drop, and the water now passes directly out of the apparatus by V into the sewer or elsewhere and no water will be delivered into the sterilizing chamber. Thus there is no danger of having unsterilized water flowing through the apparatus in case the current should fail. During the tests which were made at Marseilles, a quartz lamp of the Westinghouse-Cooper Hewitt type, with a current of 22 volts and 3 amperes was used, and the apparatus was run from August 19th until the end of September, working day and night without stopping. It gave an output of 60 cubic meters (78.5 cubic yards) per 24 hours, or 32¾ cubic yards per hour. During that time there were made eighteen bacteriologic tests of the incoming and outgoing water. Before entering the apparatus the (impure) water contained 30 to 300 germs per cubic centimeter (0.061 cubic inch) and 50 to 1,000 coli bacillus per liter (1.057 quarts). After sterilizing, on the average one germ per cubic centimeter and no coli bacillus in any case.

Following the foregoing synopsis of this recent art (photo therapeutics) it would be well to return to the rays themselves and consider them in more detail.

For a correct conception of the therapeutic value of these rays, it must be borne in mind that ultra violet rays are readily absorbed by most substances. Very few bodies are transparent to them. They even pass through air with difficulty, but they traverse without appreciable absorption quartz, Iceland spar, pure water and a variety of glass called Uviol, invented recently by Schott of Jena. Both the ultra violet and the visible rays are distinguished among themselves by their wave-lengths, which stand in an intimate though complex relation to their indices of refraction, or to the relative positions occupied by the different rays after refraction by a prism. The unit of measurement of wave-length is the micron, equal to 1/1,000 millimeter, or 1/25,000 inch. The Angstrom unit, equal to 1/1,000 micron, is also employed.

Up to the present the mercury vapor arc has been employed as a source for these penetrations, several forms of

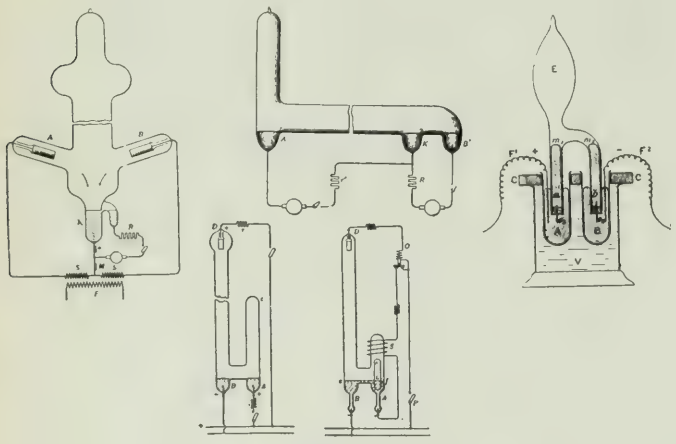

Fig. 4.

which are shown in Fig 4. All these lamps operate on the same principle, viz., metallic and carbon electrodes and a pool of mercury which is allowed to flow in a stream toward (generally the positive) electrode, thus completing the circuit and striking an arc.

The use of this lamp is attended with certain inconveniences, among which are the mechanical devices necessary to strike the arc, the high wattage and the uncertainty of maintenance. The bactericidal effect of the ray is due solely to the radiations themselves and not to any ozone or hydrogen dioxide that may be formed, for the production of an appreciable quantity of these substances requires several hours, but the sterilization is instantaneous. Bordier and Nogier and other physicists have proved that air exposed to the radiations of a quartz mercury vapor lamp acquires an odor resembling that of phosphorus, which was at first attributed to the production of ozone, but it is impossible to detect the least trace of ozone in this air, and the same odor is produced in nitrogen and other gases which contain no oxygen. In reality the odor is of physiological or subjective origin, and is due to the excitation of the olfactory nerves by the ionized and electrified air. If the gas is passed through a metal tube connected with the ground and thus deprived of its electrical charge, the odor dsappears.

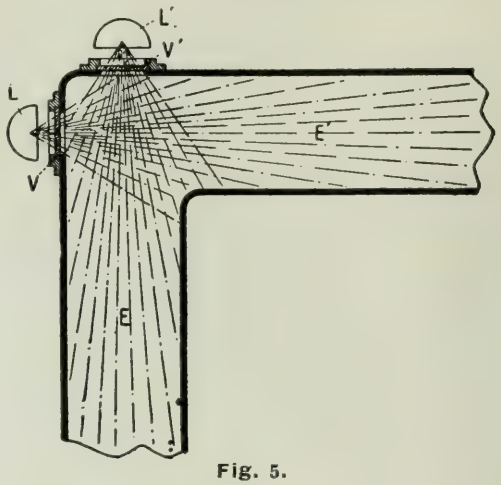

Fig. 5.

New researches by Courmont, Nogier, and Henri confirm the view that ozone and hydrogen dioxide play no part in the sterilization produced by these lamps, which is due to the direct action of the ultra violet rays. Water sterilized by this process retains its dissolved air, since it has not been heated. It remains fresh and its flavor is not changed in any way.

For municipal water service the sterilization may be effected in the water mains (Fig. 5). In order to avoid breakage of the lamps by the pressure and flow of the water they are placed outside the mains and their radiations are transmitted through windows or bull's eyes of quartz.

Some experiments are under way in the City of Toronto with the "hyper ultra violet rays." It was originally intended to generate this rays from iodine and mercury, but subsequent investigation and research showed a method of treating certain common inorganic gases with electric discharges in such a manner as to produce a volume of ultra violet rays 2,500 per cent. in excess of the mercury arc lamp. This lamp is almost devoid of luminosity under operation. Some account of the experiments and further information will be given regarding this lamp in a future issue.

SEWER SECTIONS.

Economical sewer sections have been the subject of study by Mr. Alberto Schreiner, assistant engineer in charge of design for the Bureau of Sewers, Borough of Queens, New York City. The experience in that office has led to the general conclusion that it is desirable, from the standpoint of low cost and ease of construction, to use vitrified pipe on all lines up to 24 in. in diameter. For sewers having diameters between 24 in. and 4 ft. plain concrete is believed to be the most economical type of construction but for diameters greater than 4 ft. it has been found that reinforced concrete may be used to best advantage.

HISTORY OF TAR-CONCRETE PAVEMENTS IN ONTARIO.*

By W. A. McLean, Provincial Engineer of Highways, Ontario.

Tar-concrete, or more popularly, "tar-macadam" pavements have been in service in several cities of Ontario, Canada, for a number of years, and the history of the earlier of these, while not accompanied by all desirable data, presents features of interest, in view of the growing use of bituminous materials for country highways.

Reference has, from time to time, been made in the technical press to the tar-concrete pavements of Hamilton, Ont., and it is the purpose of this paper to include also the experience of Toronto, Ont., London and other cities. In all cases the pavements have been laid by the mixing process, and coal gas tar (supposedly) was employed.

The beginning of tar-concrete roadways in Ontario was in the year 1880, when the Gas Company of Hamilton laid a short section (Mulberry Street) about 1,300 square yards, in that city. No further work of this class was done until 1891, when the same company laid 2,983 square yards at a contract price of $1.50 per yard; and in 1893 another area of 3,768 square yards was laid at a contract price of $1.75 per yard. Experience with these roadways was such that, in 1899 when a considerable extent of old cedar block pavement needed renewal, "tar macadam" was selected and about ten miles of roadway were built of that material.

Hamilton.—The following is the specification under which the later pavements (since 1899) were laid in Hamilton:—

(1) "All earth or other material above the sub-grade shall be excavated, so as to conform to the level of the sub-grade, which will be twelve inches below the finished surface of the roadway; and should the sub-grade be above the level of the natural ground, then earth shall be deposited until the level of the sub-grade is reached. The sub-grade shall be shaped to the profile and cross-section which will be furnished by the city engineer.

(2) "After the sub-grade has been formed to the proper camber of the road, generally one-half inch per foot, or six inches for a 24-foot roadway, to be thoroughly rolled with the steam roller, and if by this means soft spots are revealed, they shall be filled with good solid material.

(3) "The first six inches shall be made in the ordinary way for a macadam or telford roadway thoroughly rolled. If so required it may be made of hard broken stone, furnace clinkers, or brick rolled smooth and finished to the required camber of the road. Upon this shall be placed the tarred stone. The first layer, three inches of hand-broken stone to pass through a 2-inch ring, then a 2-inch layer of machine-broken stone, the whole smoothed off with a hand roller, and after top dressing is applied, thoroughly rolled with a steam roller. On this a layer of fine gravel and quarry clippings, mixed in equal proportions, three-quarters inch thick, shall be placed, and well rolled in so as to fill all interstices. Before finishing, a dressing of stone screenings, for the purpose of coloring, shall be scattered broadcast to be worked in by the traffic. All layers, including the coloring layer, shall be thoroughly compacted by rolling.

(4) "The stone to be tarred shall, if moist, be heated on an iron floor, under which are flues from a fire, until the moisture is driven out. The material in its heated state is then thoroughly mixed with a sufficient quantity of tar. The broken stone in warm weather may be screened, but in all cases the finer course must be artificially dried. At the same time care must be taken not to get this material too hot. The tar should be boiled in iron kettles holding one hundred imperial gallons. Eight imperial gallons should be added to each cubic yard of the coarser material or more if required to completely cover the stone, and seventeen to eighteen gallons to the finer kind of stone.

(5) "The tar must be pure coal tar free from all foreign substances, and containing not more than 5 per cent. of water, and shall contain upon analysis not less than 56 per cent. pitch.

(6) "The work must be done in the summer months, and all work must be suspended during wet weather."

The tar-concrete was used to replace cedar block pavement, and the preliminary work consisted in the removal of the old cedar blocks. As these were ten inches in depth, it was necessary to remove two inches of sand upon which they were placed, to make room for the twelve inches of macadam, and bring it to the proper elevation with respect to the curb.

The cedar blocks and surplus sand having been removed, the sub-grade was thoroughly rolled with a 15-ton steam roller.

Care was taken in forming the sub-grade, and in laying each layer of stone, to bring the surface in each case parallel to the finished crown of the roadway. The first six-inch foundation course, referred to in section 3 of the specification, was made up of flat stones, from 6 to 12 inches in greatest dimension, laid roughly by hand on their natural beds. On this, smaller stones were placed and broken into the interstices, so as to keep the bottom course in place.

The next two courses of tarred stone were then applied. Large kettles were hung close to the work, and in them the tar was kept at a workable temperature. Convenient to the kettles, the stone to be tarred was placed on mixing boards. with a dipper attached to a wooden handle, the tar was then applied to the stone, being scattered over it by a swinging motion of the dipper.

With shovels kept hot to facilitate the work, the stone was turned over twice after the first application of tar. More tar was then scattered over the stone, and the stone again turned over. These operations of tarring and turning the stone were repeated until each stone was seen to have a coating of tar, there being no bare spots on the stone. One part of tar to 22 parts of stone was specified for this course.

As soon as the stone had been tarred, it was shovelled into wheelbarrows, placed on the road to the desired depth, and raked to the required cross-section. It was found of advantage to roll the tarred stone immediately after being placed on the road, since, if left two or three days, it would not consolidate as perfectly.

The top course of fine tarred gravel was mixed in the proportion of about 20 gallons of tar to one cubic yard of gravel; or one part of tar to 8 or 9 parts of gravel. The gravel, before mixing, was screened through a ¾-inch mesh. This material was prepared in an asphalt mixer, being brought hot to the road, and carefully raked to the required grade and cross-section. This having been rolled, stone screenings from the crusher were scattered over the surface to harden it, and improve the appearance.

The cost of the various pavements varied considerably. In 1899 the average was about 79 cents a square yard, but labor then cost 15 cents an hour, and coal tar f.o.b. Hamilton $2.60 per barrel (50 U.S. gallons). The average in 1900 advanced to about 88 cents a square yard; with labor at 17 cents an hour and coal tar at $3.75 a barrel. With the

* Paper read before the American Association for the Advancement of Science.

advancing cost of labor and materials the cost in 1901 averaged nearly $1.08 per square yard exclusive of curb—about 30 cents per yard more than in 1899. Plain macadam laid in 1901 averaged 53 cents a square yard.

None of the pavements were constructed by contract, all work being done by corporation labor. The stone used was a hard limestone quarried within the city limits, the average haul to the work being 1½ miles.

Toronto. — Following the experience of Hamilton, the City of Toronto in 1900 laid an experimental tar-concrete roadway on Woolsley Street, of three blocks, or approximately, a quarter of a mile in length. This roadway did not have the heavy foundation, characteristic of the Hamilton pavements, but after the sub-grade had been carefully prepared and rolled, a course of broken limestone 4-inch in thickness, was spread. This consisted of stone not less than 1¾-inch or more than 3-inch in length or breadth. This was filled with sand, was flushed, and thoroughly rolled. On this course was spread a layer of tarred stone, which was required to be as uniform in size as possible, and not less than 1½ inches or more than 2 inches in size. This surface was evenly raked and rolled. Then a layer of ¾-inch in thickness of fine granite chips thoroughly tarred, was evenly spread over the whole surface and rolled. Before finishing, a dressing ½-inch in thickness of approved pea gravel was spread over the entire surface of the roadway, to be worked in by traffic. The specifications for mixing tar were very similar to those employed in Hamilton. Additional pavements were laid in 1901 and 1902. For two or three years, these pavements were most favorably regarded as being smooth, noiseless, sanitary and dustless, but in 1903 marked signs of disintegration began to appear, and under specifications prepared for 1904, it was then provided that there should be a foundation course 5 inches in thickness. The intermediate course of tarred stone was eliminated, and a wearing surface 3 inches in thickness was provided. Three sizes of broken stone were used in this tarred surface, viz., 1½-inch, ½-inch, and screenings. A mixture of these three sizes of stone in the proportion of two parts of 1½-inch stone, one part of ½-inch stone, and one part of screenings, was found to give a dense aggregate. During the period 1900 to 1906, there were laid in all, 7.16 miles of tar macadam roadway on the streets of Toronto.

Work carried on in 1905 required a foundation course five inches in thickness after rolling, this to be of coarsely broken stone, the surface interstices to be filled with 1½-inch stone, and covered with a layer of hot bitumen using not less than one gallon per square yard. The specification provided that:

"Upon the above foundation course is to be laid a surface course, or wearing surface thoroughly saturated with the bituminous composition. This course shall be composed of good, hard and tough limestone, samples of which must be approved by the engineer before any is delivered on the ground, and shall be equal as to quality, size and fineness to the samples which may be seen in the office of the city engineer.

"Of this mineral aggregate:

"(1) 30 per cent. shall be such as will pass a No. 40 sieve.

"(2) 12 per cent. shall be such as will be held on a No. 40 sieve and pass a number 8 sieve

"(3) 10 per cent. shall be such as shall be held on a No. 8 sieve and pass a number 4 sieve.

"(4) 18 per cent. shall be such as shall be held on a No. 4 sieve and pass a ½-inch sieve.

"(5) 30 per cent. shall be such as shall be held on a No. 12 sieve and pass a ¾-inch sieve.

"These different sizes of stone shall be heated to a temperature of at least 225 degrees Fahrenheit and not to exceed 275 degrees Fahrenheit. The No. 1, 2, 3 sizes of stone shall then be measured in accurate proportions by volume, and thoroughly mixed with a twin-pug or other mechanical mixer, the previously prepared mixture of tar and pitch shall then be added together with sizes No. 4 and 5 of the broken stone, and the whole mass mixed until the stone dust has become saturated with the mixture of tar and pitch, and is thoroughly mixed through the whole mass, and has a uniformly black appearance.

"This aggregate shall then be spread over the entire roadway to the required depth so as to produce a thickness of not less than three inches after being rolled and consolidated. The surface shall be evenly raked, rolled, repaired, brought fully up to grade and true to cross section wherever required and then rerolled until firm, compact and true.

"A flush coat of California asphalt, oxygenized asphaltum, or other equally good and suitable asphalt, in the engineer's opinion, having a melting point of about 170 degrees Fahrenheit shall be flushed over the entire surface at a temperature of at least 250 degrees Fahrenheit, so as to fill all interstices, and present a smooth, perfectly unbroken surface. A sufficient layer of good approved limestone chips, no particle of which shall be more than ½-inch in greatest dimension, shall then be spread over the whole surface and thoroughly rolled. More limestone chips shall be added where and as required from time to time, as the rolling progresses so that the whole surface is completely and evenly covered with a uniform coating of limestone dust when finished, of not less than ⅛-inch, nor more than ¼-inch in thickness after rolling has ceased.

"On commencing work a measured quantity of tar and any quantity of pitch shall be heated in separate kettles of at least 100 imperial gallons capacity. When the pitch is melted a sufficient quantity shall be added to the heated tar to make a mixture as previously determined by laboratory tests from time to time, and the whole (constantly agitated to ensure a perfectly uniform mixture) ready for use. As more is needed, measured quantities of melted pitch and tar are added in the proportions which shall be determined by laboratory test, and brought to a temperature of at least 200 degrees Fahrenheit, and not to exceed 250 degrees Fahrenheit. Reliable thermometers shall be used to determine temperatures.

"Paving pitch to have the following characteristics:— Tenacious, not relatively brittle at ordinary temperatures, insoluble in water, specific gravity of about 1.150, and have a melting point not under 200 degrees Fahrenheit.

"Tar is to be coal gas tar, should be quite thick at 70 degrees Fahrenheit, have a specific gravity of 1.200, and be entirely free from water and the lighter hydrocarbons. To ensure the above characteristics, the crude tar should be previously heated to 250 degrees Fahrenheit.

"Tar that has been refined to the desired consistency may be substituted for the mixture of tar and pitch specified. This refined tar shall have the following characteristics: Tenacious, insoluble in water, all carbonaceous matter soluble in ordinary tar menstrus, free from water and the lighter hydrocarbons. It shall have a flowing point, as determined in a dry oven, of 120 degrees Fahrenheit, and shall be similar in consistency to the standard sample which may be obtained by the manufacturer at the city engineer's office."

London.—The City of London in the year 1900 laid a tar macadam pavement on Queen's Avenue, one of the important streets of that city, of which the specification in part provided that, on the usual construction of sub-grade

should be laid a 6-inch foundation of clean coarse gravel, to conform with the cross section and finished grade of the street. Upon this foundation of gravel when thoroughly rolled was then placed 3 inches of tarred stone capable of passing through a 2½-inch ring, 20 per cent. of which being fine crushed and capable of passing through a 1½-inch ring. This crushed stone was heated on a steel platform or pans to 120 degrees, and tar composition then poured until the stone was thoroughly covered. Tar was heated to boiling point (212 F.) and pitch to about 240 degrees, and the whole thoroughly mixed. After mixing it was placed on the street and graded evenly to the required depth, then rolled with a horse roller, after which it was rolled with a steam roller. A second course 2 inches in depth of crushed stone passing through a 1½-inch and 1-inch ring respectively, mixed in the same manner, was placed and rolled with a horse roller. On this second course was then spread the finishing coat 1 inch in thickness, composed of a thorough mixture of sand, pitch and tar. The sand was thoroughly dry and heated to at least 120 degrees Fahrenheit. This coat was applied while hot, spread evenly to the proper thickness, and rolled with horse roller, after which the whole pavement was rolled with the steam roller and sanded with dry sand ½-inch in depth. Traffic was to be kept off for a period of at least one week. Tar was to be heated to 212 Fahrenheit and pitch to 240 Fahrenheit, and properly mixed in the ratio of ten gallons of tar to one gallon of pitch per cubic yard of crushed stone, and eleven gallons of tar to one of pitch per cubic yard for the top coat. Tar was required to be clear coal gas tar containing no water gas tar; the pitch also to be the best of its kind manufactured from pure coal gas tar.

Guelph.—The City of Guelph in 1908 laid one block of tar macadam. This consists of a foundation of rough stone, 8 inches in depth. On this was laid a 3-inch layer of 3-inch stone. Then followed a 3-inch layer of 2½-inch tarred stone; then a 1-inch coat of ½-inch stone tarred. Both stone and tar were heated, the hot tar being poured over the dried stone. Several other streets, aggregating 27,016 square yards have since been similarly paved. The tar is produced at the municipally-owned gas works. For both coats of stone, the amount of tar used averaged 2½ gallons per square yard.

These roadways are giving satisfaction, and show very little sign of wear. In the years 1910 and 1911 concrete foundations on tar macadam roadways were found to be cheaper than stone. In laying the surface the concrete base was flushed with hot tar. The 2-inch broken stone was then spread to a thickness of three inches, and rolled once or twice with a 15-ton roller. The stone was then sprinkled with hot tar sufficient to coat most of the stone, but not enough to fill the voids. For the surface, half-inch stone free from dust, was dried on plates and mixed on a mixing board with hot tar, then spread and rolled until well compacted.

In laying the earlier roadways the tar was boiled in ordinary tar kettles, but this method was too slow. The city now uses an old steam boiler set in brick work in the ordinary manner. The tar is emptied into the boiler from an elevated platform, and after being boiled is drawn off by a pipe from the bottom into a tank wagon, and immediately taken to the street. The only refining is by boiling. A slow fire is necessary and constant stirring to prevent boiling over. The tar is frequently tested by cooling a little in water, and the boiling is continued until the tar becomes of the desired consistency.

Ottawa.—Tar-concrete pavements were first laid in Ottawa in the year 1902, and the total length laid has been 5.15 miles. In construction, the [illegible] was graded to the required sub-grade, which was then rolled with the 15-ton roller if soft or loose, until thoroughly compacted. Upon this the spalls were placed to a depth of from 8 to 10 inches, and the top spalls broken up by hammers and made to conform to the shape of the roadway. On the spalls was placed a layer of 2-inch stone, 3 inches thick and well rolled. The next layer consisted of 2-inch tarred limestone, 3 inches thick, and put down while hot and rolled at once until cool. Great care was taken with this layer to see that it conformed to camber and grade in crown and gutter. The last coat or wearing surface consisted of a 1-inch layer of ⅝-inch tarred limestone, laid down while hot and rolled until it presented a hard, smooth surface. This surface was then dusted over with limestone dust to fill up any interstices and render it water-tight. The amount of crown on these pavements varied according to the width from 7½ inches to 8½ inches, being reduced in amount as the longitudinal grade increased.

Chatham.—One block of tar macadam was laid in 1898, but this has not been satisfactory, owing, apparently, to the surface of the tar macadam being destroyed by a coating of clay brought by the wheels of vehicles from unimproved streets. In 1910 it was sufficiently intact, however, to be used as the foundation for a bitulithic pavement.

The specifications for the tar macadam required:—An excavation 12 inches below the finished grade of the pavement; an 8-inch layer of broken stone; a 4-inch layer of tarred stone; a ¾-inch layer of fine tarred surface coating.

The stone to be tarred was spread on an iron floor, under which were flues from a fire, and heated until the moisture was driven off. The stone in its heated state was then mixed thoroughly with tar. The tar was previously boiled in an iron kettle holding 50 imperial gallons, to which was added a bucketful of pitch. Eight imperial gallons were added to each cubic yard of coarse stone, and from ten to twelve gallons to the fine stone. The cost of the tar macadam was $1.23 per square yard.

Results.—The tar-concrete roadways described, have been made from commercial tars. The work was principally by day labor under corporation foremen and engineers. Reference to proprietary tar products has been purposely avoided. The writer is not personally familiar with the first tar pavements laid, but has observed construction and results in numerous cases since the year 1900. The general history of these pavements has shown much similarity. For the first three years the surface has been all that could be desired, but about the end of that period a disintegration of the top coat has commenced. At the end of five years a mottled condition has become general, where the seal coat has chipped away, exposing the coarser bed of tarred stone. At the end of ten years the surface has become generally disintegrated, but the foundation has rarely, if ever, broken through, and a portion of the tarred surface course remains in place. Sections of the Mulberry Street pavement in Hamilton, laid in 1880, can still be seen. In no case has it been found that adequate attention has been given to the repair of these pavements by tar painting, or patching with tarred stone.

In the cities of Hamilton and Toronto, both of which have municipal asphalt plants, the tar pavements have been restored by giving a complete surface of sheet asphalt. The greater part of the tar-concrete roadways in Hamilton laid since 1899, have been treated in this way at the end of ten years, and results have been very gratifying. James Street south, in Hamilton, with central lines of car tracks, has been treated in this way, and is indicative of results under heavy traffic. Dupont Street in Toronto, constructed as a tar macadam in 1903, was surfaced with a coat of sheet asphalt one inch in thickness in 1908, and the pavement is to-day (1912)

in good condition. This was put on the tar macadam merely as a seal coat. A section taken from the pavement shows the tar to be in a plastic condition. The cost in Hamilton for the asphalt surface was 75 cents a square yard, where a binder course was required; and about 45 cents a square yard where such binder course was omitted.

Under the later Toronto specifications, in which the tarred material was proportioned for greatest density of aggregate, superior results were obtained, as for example, on Hawthorne Avenue, a street of light residential traffic. This street, paved in 1905, is now in excellent condition, and shows very little sign of surface disintegration.

The tar used was supposedly in all earlier cases, the commercial coal gas product, crudely heated to drive off water and volatile oils. In every case difficulty was found in obtaining a uniform quality, and no doubt much of the disintegration was due to the use of inferior tar. In view of the fact that in English practice a desirable tar contains not over 2 per cent. of water, or 5 per cent. of volatile oil, that it shall have at least 80 per cent. of pitch, it is apparent from the specifications quoted in this paper, that earlier Canadian construction was very indefinite in this regard and permitted the use of a quality of tar not now sanctioned.

The tar pavement in Chatham is interesting from the fact that its more rapid disintegration apparently resulted from clay being tracked on from adjacent streets, and would corroborate the experience suggested by the State Highway Engineer of Maryland, that clay would appear to have an emulsifying effect on bituminous binders.

A side-light is thrown on the use of tar by experience with foot-walks of tarred gravel. Early in the history of tar pavements, sidewalks were used, but have now been almost entirely displaced by the more durable, but less agreeable, cement concrete walks. These walks were laid by first putting down a foundation layer of gravel, which was well consolidated by pounding. On this was spread a three-inch layer of tarred gravel, well rammed, and this finally given a paint coat, and sprinkled with clean, coarse sand. The tar used is the ordinary commercial gas tar, merely heated to permit mixing with sub-dried gravel. Enough tar is used to coat each particle of gravel, about one part of tar to eight or nine parts of gravel. It is considered of primary importance to obtain a firm and unyielding foundation, and to thoroughly consolidate the tarred material. In Richmond Hill a hamlet near Toronto, these walks, for example, were first laid in 1886; the earlier and more experimental were not a success, but others laid in 1889 are still in use. These, every two or three years, are given a paint coat of tar, gritted with clean, sharp sand. Made of gravel, there is a tendency for the crown to flatten not apparent in pavements of crushed stone.

Owing largely to the reduced price of asphalt, the use of tar (other than proprietary forms of construction) has been discontinued in Hamilton and Toronto, these having municipal asphalt plants. Ottawa has stopped the use of tar for this reason, and also because of the uncertain results which have attended its use there. The city of Guelph, having a municipal gas plant, continued the construction of tar concrete roadways, using some care, however, in refining the tar to remove water and volatile oils.

Were exact data available as to the quality of material used, and variations from the prescribed specifications, numerous positive conclusions might be deduced from the tar concrete work described. Under the circumstances, while reasonably positive in certain particulars, other factors are merely suggested. It may, the writer believes, be concluded that tar of uniform quality, and of composition within certain range of proportions, while susceptible to extremes of temperature, becoming brittle and slippery in cold weather, and soft under midsummer extremes of heat, is not debarred by climatic or other conditions, as a useful road material; that best results require a dense mixture, preferably proportioning the aggregate for maximum density, in order that internal deterioration will not occur from moisture or atmospheric action; that some doubt may be attached to the complete durability of bituminous surfaces made by the penetration process, in which density of aggregate is lacking, and suggesting that the grading of stone in this method, rather than having a uniform size, is desirable; that a moderately coarse aggregate should be brought to the surface, as far as practicable, to overcome slipperiness and take up wear; that tar-concrete is less durable under concentrated wear than is sheet asphalt, wearing rapidly when laid along street car tracks where traffic is confined to narrow lines, but is more resistant to moisture as indicated by the greater durability of tar in gutters; that broken stone will provide a more stable structure than will water rounded gravel when bonded by tar; that a paint and grit coat is necessary as a preservative as frequently as signs of surface wear or oxidation appear; and it is probable that such treatment will add to the durability of any bituminous pavement, restoring necessary oil, and not merely repairing the worn surface but gradually increasing its thickness.

MINE ACCIDENTS IN CANADA.

Statistics recently compiled by the Commission of Conservation show that the death rate in Canadian coal mines is much higher than in any other civilized country. In 1902, the year of the Fernie disaster, the death rate per 100 men employed (above and below ground), reached the maximum rate of 13.25. The average rate for the ten years preceding 1910, however, was 4.79. The United States comes next with an average rate for the same period of 3.43. Perhaps the worst aspect of the situation is the fact that the death rate from coal mine accidents has been steadily on the increase in Canada for a number of years. The minimum rate of 1.83 was reached in 1897. In 1909 the rate was 4.21. During the same time there has been a steady decrease in all the leading European countries.

It would, of course, be unreasonable to expect that the loss of life and property could be entirely done away with, but experience has shown that careful investigation of the conditions will point the way to the remedying of many abuses. That the danger inherent in coal mining can be largely eliminated is shown by the low, constant death rates in Belgium and Great Britain. Coal mine explosions are much more frequent in Canada and the United States than in any of the European countries. The following example is exceedingly significant. In 1850 the fatality rate in the Belgian coal mines was as high as the present Canadian death rate, while at the present time it averages the lowest in the world. This decline in the death rate was due to the combined efforts of the mine owners, the workmen and the Administration of Mines. to the diffusion of technical and professional knowledge and to the administrative organization for the scientific study of accidents.

Although the death rate in metalliferous mines in Canada is lower than in the coal mines, it is much higher than in any of the European countries. The death rate in Canada for the period 1900-1909 was 3.82.

With the exception of the Kimberley diamond mines and the Transvaal, where native and Chinese labor are employed, the fatality rate during this period (1900-1909) was considerably lower elsewhere than in Canada. It requires no discussion to emphasize the importance of an inquiry into the whole subject of fatal accidents in the mines of Canada.

WORK OF CANADA'S CONSERVATION COMMISSION.

BY HON. CLIFFORD SIFTON.

During the two years that the Commission of Conservation has been in existence Canada has made substantial progress in the work of conserving her natural resources. That this is so is due largely to the effective co-operation of the general public and of the Dominion and Provincial governments. The Commission is merely an advisory body, and its success, therefore, depends upon the support given it by public opinion and by the various governments adopting its recommendations. The fact that the Dominion and Provincial ministers who administer natural resources are ex-officio members establishes a connection that conduces very largely to effective work.

What has been done in the way of actual accomplishment since the inception of the Commission may best be presented under the head of the different resources. The initial work consists largely in discovering what we have, and in ascertaining the efficiency of our present methods of development. This is particularly applicable to lands. To ascertain the state of agriculture, the committee on lands of the Commission has, with the assistance of the agricultural colleges and the deputy ministers of agriculture of the various provinces, for the past two years conducted a survey of one hundred representative farms in each province. The investigation disclosed the fact that only about nine per cent. of the farmers of Canada followed any effective and intelligent system of crop rotation. After fully considering the data obtained, it was estimated that the quantity of field crops in Canada could be doubled in twenty years by the adoption of such measures as may now be easily taken.

The committee on lands is also conducting experiments with alfalfa in Quebec to find out in what districts and under what conditions this crop can be most profitably cultivated. The experimental plots are located on farms throughout the province, and the operations are being supervised by Prof. L. S. Klinck, of Macdonald College. The plots, in addition to being used for experimental purposes, will also illustrate to the surrounding farmers the best way to grow this important crop.

In regard to forestry, attention has been concentrated upon the prevention of forest fires. Investigations conducted in the field by skilled woodsmen showed in 1910 that about thirty-four per cent. of all forest fires for which causes could be assigned were due to railway locomotives. The Commission, therefore, recommended to the Dominion Government that legislation be passed penalizing railways for fires set by them. A conference of the Minister of Railways, the chairman of the Railway Commission and myself was held, and, in the last Parliament, Hon. G. P. Graham had an amendment to the Railway Act passed empowering the Railway Commission to compel the railways to maintain an efficient and properly equipped fire patrol. The law now provides also that railway companies shall be liable for damages caused by sparks from their locomotives, whether it was shown they were guilty of negligence or not, said liability for damages not to exceed $5,000 if modern and efficient fire-preventing appliances were used.

A further recommendation of the Commission was that the eastern slope of the Rocky Mountains be set aside as a permanent forest and game reserve. This reservation was made by an Act of the last Parliament introduced by the Hon. Frank Oliver, former minister of the interior. An area exceeding 14,000 square miles in this part of Canada is thus reserved, constituting an important regulating influence for the water supply of the Prairie Provinces, a great forest reserve, and the largest national park in the world.

The province of Ontario is in the front rank in regard to the setting aside of forest reserves. Under the administration of the Hon. Frank Cochrane, late minister of lands, forests and mines in the Ontario government, certain lumbering rights, both within and without the boundaries of the Algonquin National Park, were extinguished and the park considerably enlarged. The question of still further extending the boundaries of the park is now receiving the attention of the Provincial Government.

New Brunswick last year also made a forward step in its forest policy. Largely through the efforts of the surveyor-general, Hon. W. C. H. Grimmer, the provincial legislature adopted the policy of prohibiting the export in its raw state of pulp-wood cut from Crown lands. There are now four provinces—Ontario, British Columbia, Quebec and New Brunswick—that have stimulated the pulp industry by such measures.

The work done by the Commission of Conservation in connection with mineral resources is summarized in a report issued in 1911. This includes a digest of the mining laws of Canada and an article by W. J. Dick, mining engineeer to the Commission, giving the known extent of our mineral resources, and indicating how waste can be further eliminated in their development. Mine accidents, in which Canada does not hold an enviable record, are also treated in some detail. During the past summer Mr. Dick investigated mining methods in the coal mines of British Columba and the West. The results of this work will be published later.

HON. CLIFFORD SIFTON,
Chairman of the Commission of Conservation, Canada.

In connection with fisheries and game, the aim of the Commission has been to collect information to form a basis for future work. This has been published in a report in 1911. An analysis is given of the British North American Act, showing the jurisdiction exercised over fisheries by the Dominion and each of the provinces; while a digest has been made of federal and provincial fisheries laws and regulations. The report also contains the results of an investigation into the Canadian oyster industry.

The public health division is investigating housing and town-planning conditions in Canada. Information is being compiled showng the park area of each city, and indicating what power, if any, urban municipalities have in determining how areas on their outskirts may be subdivided into lots. From investigations already made it has been ascertained that Canada is face to face with a serious slum pro-

blem, and Dr. C. A. Hodgetts, medical adviser of the Commission, has spent several months in Europe investigating housing conditions and town planning there. A thorough investigation is also being made of infantile paralysis, a disease that has recently become alarmingly prevalent in Canada.

The greater part of the work of the Commission on waters and water power is embodied in a report on the water powers of Canada by Leo G. Denis and Arthur V. White. This is a very exhaustive work, which, after recounting the general economic conditions regarding water resources, gives comprehensive and detailed information respecting the water-powers of each province. The head of the fall, the amount of power now developed, the amount possible of development, and the purposes for which the power is used are given, wherever the information is available, for each known water-power in Canada. In addition, a summary of the laws of each province and of the Dominion governing the disposal of water-powers is included. It is hoped that this information in readily available form will do much to encourage the development of Canadian water-powers.

The available data for the Western provinces was found to be very incomplete, and, accordingly, Mr. L. G. Denis, the hydro-electric engineer of the Commission, and Arthur V. White were detailed to investigate these powers during the past summer. Mr. Denis, last summer, surveyed the powers in northern Alberta, and Mr. White, with several assistants, was engaged in surveys of the water-powers of southern British Columbia. Through the courtesy of the Honourable W. R. Ross, chief commissioner of lands for British Columbia, the information respecting water-powers obtained by provincial engineers employed by the water commissioners in connection with the disposition of water rights was placed at Mr. White's disposal.

Additional information of value on the water resources of the province will be brought out in stream-gauging operations to determine the amount of water available for irrigation purposes. These surveys are being undertaken to comply with the provisions of the British Columbia water-power Act, and are being carried out under the direction of the Hon. Mr. Ross.

The Commission has reported on various projects for the development of water-powers that have come up before parliament. The most important of these was the application made by American capitalists to dam the St. Lawrence at the Long Sault rapids. This power is estimated to be capable of generating 600,000 horse-power, and the projected plans gave a minimum consideration to Canadian interests, it being proposed to develop only one-sixth of the total power on the Canadian side. On grounds of public policy the Commission opposed the application, and thus far successfully. The Commission also reported adversely on the incorporation of the International Waterways Canal and Construction Company, a scheme for canalizing the waterways between Lake Superior and the head waters of the Saskatchewan, which, it was feared, would interfere with public rights. The Nelson River Railway Company sought to gain possession of valuable water-powers, including the Grand Rapids of the Saskatchewan—the most valuable water-power near the settled area between Lake Superior and the Rockies. At the instance of the Commission it was modified so as to be unobjectionable. The Nipigon-Albany Canal and Transportation Company applied for a charter that would have given them control of the powers between the mouth of Nipigon River, on Lake Superior, to the mouth of the Albany, on James Bay. Warned by the fate of the International Waterways, Canal and Construction Company's bill, its promoters withdrew it. Other projects on which the Commission reported were: the St. Lawrence Power Transmission Company, and the application of the Minnesota and Ontario Power Company to export power from Fort Frances, Ontario. In all these cases the Commission has endeavored to follow the policy it has laid down for itself in this regard, viz.:—

That no unconditional titles should be given to water-powers, but that every grant or lease of powers should be subject to the following, among other, conditions:—

1. Development within a specified time.
2. Public control of rates.
3. A rental, with the power to revise same at later periods.

In view of the heavy losses due to the destruction of property from fire in Canada (from seven to ten times as great as in the larger European countries) an investigation is now being made of this subject by Mr. M. J. Patton, assistant secretary of the Commission. If means can be devised to lessen these losses it will mean a large saving both in property and insurance rates.

CONTROLLABLE DUMP BUCKET FOR PLACING CONCRETE IN THIN WALLS.

In the construction of concrete work contractors have often found it difficult with the ordinary drop bottom bucket to place concrete in thin walls, as most of these buckets on the market have uniformly sloping sides or the dumping mechanism is located on the front or discharge side where its operation is often interfered with by the reinforcement rods or forms.

With the idea of overcoming this difficulty a drop bottom bucket has been designed, the section of which is a right-angle triangle, the front or discharge side being vertical. It is evident by this arrangement that there is no interference from the steel reinforcement rods or forms in the operation of the bucket mechanism.

The construction of this bucket is very simple. The drop bottom which is slightly curved is about quarter of the length of the sloping side. It is operated by a handle, on the end of which is a cam bearing on an equal arm lever that connects through another lever to the drop bottom. The discharge of the concrete is readily controlled by the operator, who can let the concrete out in small or large quantities. In cases where thin layers of concrete are desired the operator can control the discharge and move the bucket forward or backward as desired, thus spreading the mass. The shape of the drop bottom is such that with a little experience the operator can throw the concrete through a steel system four to six feet wide.

This new bucket, while it was primarily designed for thin wall construction, discharging concrete readily in narrow forms for walls only 3-inch thick, without any waste of concrete or any extra handling, will be generally useful in all kinds of concrete work, and the shape of this bucket is such that very little scraping is needed after the batch is let out. The vertical face gives a clear fall to the batch of concrete, which draws the concrete down with such force that a scouring is produced on the sloping side and the bucket is cleaned completely. This is a point which means saving of time, and also saves the bucket from the hammering commonly needed to clean so many buckets on the market.

It has been used with success by Contractors J. B. Smith Company, in erecting the inclined concrete abutments for the overhead double track crossing on the Western and Atlantic Railway at McCarty, Tenn. The bucket has just been put on the market by the manufacturers, Ransome Concrete Machinery Company, Dunellen, N.J.

MINING IN BRITISH COLUMBIA.

BY ROBERT R. HEDLEY.

The British Columbia mining industry has made considerable substantial progress during 1911, though the tangible results are not yet very evident. In all directions, there is a promise of more activity throughout the province in the next twelve months, and there is no doubt that the very decided favorable development now assured in many properties will greatly stimulate this.

This development has been quietly proceeded with, by substantial financial companies, and it is not easy to get particulars of results achieved. Coal must in the near future gain for us a great reputation.

Men of high standing in the mining world have said there may be a second Pennsylvania around the headwaters of the Skeena River. Certain it is that there are large areas underlain by several seams of coal of very satisfactory thickness, and of exceptional quality. Authorities class it as high grade anthracite. After the Toronto syndicate the National Finance Company, Limited, of Vancouver, was among the first in the field and secured some very valuable areas. Other Vancouver as well as Ontario and Quebec capital is interested. The importance of the field, and the need of its produce, ensure the speedy providing of transportation. There is, of course, coal distributed through a wide section of the Skeena River country, but it has not received so much attention as that mentioned.

Copper River has an area of great promise which is owned and being developed also by the National Finance Company, Limited. Graham Island, doubtless, has large areas underlain by coal, but though known for the past half century, the only development is at camps Wilson and Robertson, and nothing is very definitely proven. At the present time, however, drilling is in progress by people of weight and experience. It is generally accepted that the quality will vary greatly from anthracite near the eruptives to lignites, also the ash will be a variable figure. On Vancouver Island there has been no material change since the Dunsmuir property changed hands.

The production is about the same as of recent years. At Nicola Valley, the conditions are constantly improving and the field becoming more important. The areas to the south, in the Similkameen, Tulameen district have coal of varying character, but generally low in grade. Development as yet is confined to one property. The Crows Nest and Alberta colliery output has been sadly curtailed by the ill-advised and unfortunate strike now happily settled. Vast new fields are under process of development from Elk River to Northern Alberta, which promise to amply supply the needs of the country tributary to that section, with coal of any variety in any quantity.

At the Coast, the Marble Bay Copper Mine on Texada Island has continued to produce very profitable ore at the rate of from 1,000 to 1,200 tons per month. It is noteworthy that this mine, though operating at a depth of over 1,000 feet below sea-level, still produces the higher sulphides of copper, bornite and chalcocite, and maintains its gold and silver values. The ore shoots have been practically continuous from the surface. The property is owned in Tacoma, Wash.

The Britannia Mine, in Howe Sound, thanks to the faith and persistence of the owners, aided by the unusual energy and capability of their manager, Mr. R. H. Leach, has now an assured future, with a very large tonnage of profitable ore blocked out, and a very much greater quantity, proven by partial development and diamond drilling.

The Hidden Creek group of mines is situated on Goose Bay Observatory Inlet, a branch of Portland Canal. In 1907 this was a prospect pure and simple outcropping as a vast pyritous deposit, offering bluffs of 200 feet in height and width somewhat greater. It was apparent that a large tonnage of ore could be mined to carry from four to five per cent. copper, and that lower grade ore would be developed in great quantity. It impressed me as offering great possibilities for profitable operation if developed and equipped for economical mining and smelting. The character of the ore and its favorable situation were most promising.

Last year this property was purchased by the Granby Consolidated Mining, Smelting and Power Company, who have further developed it, and are now planning the erection of a smelting plant with a capacity of 2,000 tons per day. The measure of their success depends on their metallurgist. There is every reason to expect unusual results in operating costs of a different character, and not yet well developed is the Surf Inlet Gold Mines on Princess Royal Island, now being developed by a local company. In proximity to this, as distances go in the Coast district, Messrs. Martin and Shannon have done much costly and difficult work in tracing a quartz vein, that, so far as proven, has wonderful shoots of high grade copper-gold ore. This is six miles from the head of Khutze Inlet.

It is conservative however, to state that the limited development so far accomplished, indicates probable ore in excess of 100,000 tons, with gold values approximating ten dollars per ton. This should yield a profit, according to the equipment and tonnage treated, of four to five dollars per ton. A force of men will further develop the property this winter under the supervision of Mr. F. M. Wells, to whom with Mr. A. B. Clabon, is due the credit for the resuscitation of this promising property. A grand waterpower of untold capacity and cheaply developed, is an important asset of this company.

At Portland Canal, there has been but little accomplished except for two properties, though there are many properties waiting development that have every promise of winning out. The Portland Canal Mining Company's property is well developed and equipped with a modern concentrator. The margin of profit, however, is not great and the plant too small as yet for substantial results.

The Red Cliff has insufficient development to estimate its ore reserves, or to enable it to enter the producing list. The lower tunnel has cut the ore at a depth of 275 feet below the main outcrop and a raise connects. Development is under progress and the outlook is hopeful.

On the Salmon River are some very promising prospects, indicating large bodies of ore which, though low grade, will probably prove profitable.

There are many excellent opportunities for exploitation, notably some deposits of copper ore similar to that of the Britannia, between the headwaters of Seymour Creek and Howe Sound, and up the Squamish River as far as Green Lake.

Lillooet has in the past two years received increasing attention from prospectors and others, and there are indications that the general condemnation of that district, which followed the Golden Cache fiasco, was unwarranted.

Of the country known generally as the Hazelton district and comprising all that between the Telkwa, Copper and the Babine Rivers, there is little to say and much to expect. This district has much promise of ore of great variety, some of the silver-lead properties seeming to stand the test of development very well.

Of Kamloops, it is still playing the waiting game. Let us hope it will be worth waiting for. I believe it will if properly handled.

The Boundary with its two smelting plants always on the eve of breaking the already low record of costs and high record of production, has this year been handicapped by the failure of the coke supply. Granby thought it unwise to continue to bring coke from Pennsylvania and shut down the mines and plant, while the British Columbia Copper Company worked right through on Pennsylvania coke.

It is extremely gratifying that both these companies are extending their operations to other fields, the Granby having established themselves on the Coast at Observatory Inlet, and the British Columbia Copper are again looking into the copper camp tributary to Princeton, as well as investigating gold property on Slocan Lake.

The Consolidated Mining and Smelting Company of Canada, with their ample plant at Trail, are producing lead, silver, gold and antimony, as refined products, but the majority of their gold still goes with copper matte to the refinery in the United States. This plant, embracing all that is most modern in the copper and lead smelting and in the electrolytic treatment of argentiferous and auriferous lead bullion, draws supplies from a number of its own mines, as well as serving the country as a custom smelter. Among land; St. Eugene, Sullivan, East Kootenay, Molly Gibson and Richmond Eureka in Ainsworth-Slocan, Slocan. Others there are of lesser importance as yet, though the big ledge or deposit of carbonate of lead near Sheep Creek, may ere long be claiming recognition. The recent development of the War Eagle has opened extensive stopes of unusually high grade ore at several levels, including the lowest, an encouraging feature.

Nelson district looks forward to the opening of the Toad Mountain mines, including the old Silver King and Dandy, under new auspices. The capitalists backing this venture are advised by Messrs. C. Nelson Fell and M. S. Davys, both of whom have experience on the Mountain. Sheep Creek has not made as substantial progress as was looked for. The Mother Lode ceased mining to erect a modern mill which is expected to make a handsome profit.

The Mother Lode is the one mine really developed and ready for milling, though the Nugget could probably be rendered so by moderate, judicious expenditure.

In Ymir camp the old Wilcox has changed hands and is being well equipped. Recent development has been satisthese are the War Eagle, Centre Star and Le Roi, of Rossfactory. The Yankee Girl too, has passed from the receiver's hands to those of a strong aggregate of capital, headed by Mr. Bob Mabry, of Spokane. This mine has under the old regime shipped a handsome tonnage of ore to Trail, which has averaged about $20 per ton, chiefly in gold, but at a low margin, owing to lack of proper development and equipment.

Below Salmo, the Arlington at Erie continues to produce a small tonnage of sorted ore with a narrow margin of profit. Conditions are none too favorable and the operators are deserving of great credit.

Nearer Nelson, the Athabasca and Poorman-Granite have rendered a good account, milling steadily a fair tonnage of good grade. Rossland, in addition to the mines owned by the Consolidated, can point with pride to the record of the Le Roi No. 2, which has been a continuous producer of higher grade gold-copper ore, with a handsome profit.

West of the Boundary, though the field is wide and the promising properties are many, the only producer of note is the Hedley Gold Mines at Hedley, on the Similkameen. Under the new management this plant has been remodelled and is now an efficient and modern milling and cyaniding mill. This year's results will in all probability total better than 50,000 tons of $12 ore, and will have something over for surplus after paying $240,000 in dividends.

In the Slocan there is the strongest possible feeling of confidence in the future. Six years ago the Rambler-Cariboo drove a deep level tunnel, 4,000 feet, to tap the ore 1,400 feet below the surface and 600 feet below the lowest workings. Success was not, however, immediate, and it is only this year that they really see their reward. Always a high grade silver lead ore, the ore now developed is greater body and higher grade than ever before. Forest fires in 1910 destroyed the railway, and shipping must wait till transportation is restored. As a result of this deep level success, the Payne Mine, now opened to the eighth level, is to be provided with a deep level about 3,300 feet long, giving 675 feet of virgin ground. This is undertaken on the recommendation of Mr. W. E. Zurickey, manager of the Rambler-Cariboo, and to him will be entrusted the engineering of the project.

The Whitewater Deep has this year connected its deep level tunnel by raise with the upper levels, and exploratory work so far has been very encouraging.

The Slocan Star group under a new company, has also started a deep level which will deliver ore direct to the concentrator. The tunnel will be 2,300 feet long, and give 600 feet of virgin ground on the dip of the vein.

On Slocan Lake, the Standard, recently acquired by Patsy Clark, has in its deep levels, spectacular stopes of over 20 feet of galena practically without gangue, and very extensive bodies of concentrating ore for which a mill is being installed. The Van Roi will this year make a very satisfactory record from its milling operations, treating 100 to 125 tons daily. The development is extensive and good and the ore reserves assure a long life.

The Hewitt-Lorna Doone group of the Silverton Mines, Limited, is well developed by seven levels, several of which pierce the mountain from west to east. No. 6 connects with the upper terminal of the tram, which delivers to the mill on Four-mile Creek.

COST OF BITUMINOUS COAL MINING.

At the Chicago meeting of the American Mining Congress, B. F. Bush gave the following as the averages of answers to questions he had submitted to the leading bituminous-coal operators of the United States:—

1. Capital invested in business. For each ton of coal sold $1.41 is invested in land, machinery and equipment.

2. Average total cost of production, labor cost (mine workmen only), administration and average selling price at mine. Total cost in 1910 averaged $1.07, including 95c. for labor and supplies. Administration cost 12c. per ton, including office and sales expenses, insurance, taxes, legal advice, etc., but not including depreciation, interest nor profit. Average selling price at mine, $1.11 per ton.

3. Estimate of increased cost necessary to meet demand for conservation. Two to 15c. in different fields, averaging perhaps 5 cents.

4. Depreciation per 100 tons daily capacity. About 4c. per ton covers the average depreciation of coal reserves and plant.

5. At what price must coal sell? The increased prices necessary for a fair return on the money invested range from 5 to 25c., averaging 12 cents.

Over-production, over-capacity and ruinous competition were discussed at length. Two possible remedies were suggested.

District sales agencies to control prices and output, under subjection to an interstate coal commission; government assistance in encouraging foreign markets.

The Canadian Engineer

ESTABLISHED 1893.

ISSUED WEEKLY in the interests of the CIVIL, MECHANICAL, STRUCTURAL, ELECTRICAL, MARINE AND MINING ENGINEER, THE SURVEYOR, THE MANUFACTURER, AND THE CONTRACTOR.

Managing Director: JAMES J. SALMOND.
Managing Editor: T. H. HOGG, B.A.Sc.
Advertising Manager: A. E. JENNINGS.

Present Terms of Subscription, payable in advance:

Postpaid to any address in the Postal Union:

One Year	Six Months	Three Months

THE UNIVERSITY AND THE RAILWAYS.

The man in the street does not usually see any intimate connection between the work of the Engineering School and the railways. He, of course, appreciates the fact that a great many of the men in executive positions on the railways have had an engineering education. However, the fact that many of the engineering schools have been developing and analyzing many problems of great practical interest to these corporations is not very well known.

Dean Goss, of the Engineering Faculty of the University of Illinois, in a recent address to the St. Louis Railway Club, refers to a number of these problems, which are being solved in that college.

The school of railway engineering and administration is developing on its engineering side many interesting problems. For example, a knowledge of the forces which must be applied to maintain the motion of railway trains is a matter of fundamental importance in many of the problems of the railway. The University of Illinois was almost a pioneer in this field of research. In conjunction with the Illinois Central and the Cleveland, Cincinnati, Chicago and St. Louis, it designed and constructed a series of dynamometer cars, each new design overcoming defects which had appeared in its predecessor. The third car of the series has now been in successful operation for the past three years, and it has served in the development of the most accurate array of data concerning train resistance which has thus far been published.

Another important line of investigation has led to the development of a system, not entirely original, for detecting defects in track bonds on electric lines. An electric test car has been equipped with apparatus designed to record automatically the condition of every bond it passes over. The record gives the electrical resistance of the joint, in comparison with the resistance of a short length of solid rail. The results are registered on a web of paper, which unrolls as the car proceeds, a half-inch length of paper corresponding to a rail length. In action the car is allowed to proceed at a moderate speed, the record for each joint being made automatically as it is passed, while an attendant operating a push-button controls a supplemental record representing the location of the numbered line poles as they are passed. An examination of the record enables one at once to pick out and locate the imperfect bonds. The test-car has the form of an interurban car, the interior being fitted up with the instruments necessary to make it a laboratory. It is designed for the instruction of students and for the solution of problem of interest to the electric traction interests.

The university is giving generous attention to problems underlying the design of railway equipment.

A standard Master Car Builders' drop testing machine has been installed, which is designed especially for use in testing couplers, coupler knuckles and draft gears, but is available for use in testing materials of many different sorts. The machine consists of a hammer weighing 1,640 pounds, sliding in two upright guides 50 feet in height, between which it is allowed to fall upon the test specimen supported by a massive anvil resting upon a foundation through the medium of heavy springs. By the use of this machine students are instructed in the process of making the proof tests of the Master Car Builders' Asosciation, and are enabled to gather impressions concerning the severe treatment which must be withstood by couplers, draft gears, bolsters, axles and other details entering into the construction of freight cars.

Another detail in car design which of late has demanded attention is the brake shoe. There has been installed a brake shoe testing machine possessing equivalent characteristics to those of the original Master Car Builders' machine, but one which in its details is a much more serviceable machine. It consists primarily of a shaft carrying a fly-wheel and standard car wheel, which may be either steel or cast-iron. The shaft is driven at any desired speed by means of an independent engine. By reason of the presence of the fly-wheel there is available at the surface of the car wheel, when in motion, the same amount of energy as is impressed upon one wheel of a 60,000-pound capacity car in service under like speed conditions. The shoe to be tested may be applied to the wheel with any desired pressure up to a maximum of 24,000 pounds. The tangential pull of the shoe, which develops when the shoe is thus applied to the moving wheel, is transmitted to a dynamometer, where it is recorded upon a moving paper chart. By these means the coefficient of friction of any shoe may be determined under different conditions of speed and shoe pressure. The machine likewise serves to permit the determination of shoe wear and wheel wear under any condition that may be prescribed.

The last Legislature appropriated to the university $200,000 for a building and equipment for its college of engineering. The trustees have determined that the building shall be devoted to transportation interests, and in the working out of plans it has seemed best to provide for a group of buildings.

After reading what Dean Goss states is being done for the practical solution of railway problems by the University of Illinois, it appears to us that there are many ways in which our Canadian universities can develop the practical side of their work.

The faculties of engineering in Canada are rapidly increasing their staffs, and a great deal of public money is being invested in laboratories and laboratory equipment. These laboratories and equipment should be used for the public benefit to as large an extent as possible, and for that reason the work done in them should be kept along the lines which will be of benefit to the public. The danger always will be of the laboratory work given in connection with the engineering courses becoming too academic.

EDITORIAL COMMENT.

What has become of the Royal Commission on Technical Education? We would suggest that it is nearly time they handed out their report.

* * * *

The annual meeting of the Canadian Society of Civil Engineers is to be held in Montreal, January 24th, 25th and 26th. The programme of the meeting will be found in this issue of The Canadian Engineer. Every member should make an effort to be present.

THE DINNER OF THE FACULTY OF APPLIED SCIENCE, UNIVERSITY OF TORONTO.

The twenty-third annual dinner of the Faculty of Applied Science and Engineering, University of Toronto, will be held on Thursday, January 18th, in Convocation Hall, at 8 p.m.

Among the speakers expected to be present to address the students are Major R. W. Leonard, chairman of the Transcontinental Commission; the Hon. Adam Beck, chairman of the Hydro-Electric Power Commission; Mr. G. H. Duggan, Chief Engineer of the Dominion Bridge Company; Mr. W. H. Hearst, Minister of Mines of Ontario, and many other prominent men. It is expected that there will be a good turnout of the graduates as well as of the students.

PROGRAMME OF THE TWENTY-SIXTH ANNUAL MEETING, CANADIAN SOCIETY OF CIVIL ENGINEERS.

The annual meeting for the election of officers and members of council for 1912, and for the transaction of business, will be held as follows in the rooms of the society, 413 Dorchester Street West, Montreal.

Wednesday, January 24th.—10 a.m. Meeting for the nomination of scrutineers, receiving the report of council reception and discussion of reports of committees, and transaction of the general business of the society.

1 p.m. Adjournment for members' luncheon in the Windsor Hotel, Montreal, to which the visiting members are invited by the members resident in Montreal.

3 p.m. Continuation of the business meeting for the discussion of reports, etc.

4 p.m. An address by the retiring president, Mr. C. H. Rust.

8 p.m. Address by Dr. H. T. Barnes on "Iceberg Detection in Navigation," in the lecture hall of the Chemistry Building, McGill University.

9.30 p.m. Reception by the president and members of council in the Engineering Building, McGill University, and inspection of the laboratories and workshops.

Through the courtesy of the Board of Governors of the University, the building has been placed at the disposal of the society for this evening. Members and ladies accompanying them are invited to the reception and lecture. Cards will not be issued.

Thursday, January 25th.—Two parties will be formed for the purpose of visiting engineering works.

(a) The Angus shops. By the courtesy of the Canadian Pacific Railway Company, a special train will convey this party to the works, leaving the Windsor Station at 10 a.m. Dining cars will be attached to the train, and luncheon will be served during the inspection of the works.

(b) The works of the Dominion Bridge Company and the Canadian Car and Foundry Company. By the kindness of the Montreal Street Car Company, cars will be in waiting at the Windsor Hotel, and will leave there at 10.30 a.m. sharp, for Dominion. The Bridge Company will lunch this party at 1.30 p.m., and the works of the Canadian Car Company will be visited on the return journey.

8 p.m. Annual dinner in the Windsor Hotel.

Friday, January 26th.—10 a.m. Meeting for the reception of reports of scrutineers and conclusion of the business of the annual meeting.

3 p.m. Meeting of council.

By the kindness of the railways of the Eastern Canadian Passenger Association, members and their families who have paid a full one way first-class fare going to the meeting in Montreal, will be returned free on presentation of a standard convention certificate signed by the ticket agent from whom a ticket has been procured at the point of commencement of the journey. The certificate is to be endorsed by the secretary of the society, and to be vised by a special agent of the Passenger Association who will be in attendance at the meeting from 3 p.m. to 6 p.m. on Wednesday and Friday, January 24th and 26th. A fee of 25 cents will be charged by the

Passenger Association in each case. Tickets may be purchased and are available three days before the commencement of the meeting, and the return journey may be made three days after its conclusion.

The Canadian Pacific Railway and the Canadian Northern Railway will grant a further extension of time to persons residing west of Fort William, making this free return available for 15 days after the close of the meeting; the ticket to Montreal having been purchased at any time and receipt obtained therefor on the standard convention form as above.

Tickets to the luncheon may be purchased at the rooms of the society. Prices: Luncheon $1.50 to resident members, dinner $3.00. C. H. McLeod, Secretary.

SILVER AND GOLD MINING IN ONTARIO.

BY H. E. T. HAULTAIN.

During the past year Cobalt has proceeded along the steady course of middle age without any remarkable occurrences. With the good properties the luck has held and new ore bodies have been discovered in proportion to the amount of exploration work carried on. The output has been steady and increasing and the price received for the silver was higher than during the previous year. Perhaps the most noteworthy event has been the completion and successful operation of the mill at the Nipissing designed by Charles Butlers for the treatment without smelting of the high grade ores of that company. No particulars have been made public but apparently the process is mainly amalgamation and lixiviation which recover the silver as bullion and leave the cobalt and arsenic as a tailings product to be subsequently re-treated when the market justifies.

Nothing has developed during the year to raise any reasonable hopes of finding extensive ore bodies below the Huronian. Cobalt camp is a notable example of local geological conditions sharply defining the depth beyond which commercial values are very unlikely to extend. That a young camp in a restricted area should produce sixteen million dollars worth of metal in a year is remarkable, and it is still more remarkable that nearly all this output should come from above the 250 foot level. Nearly all of the final total output of Cobalt is to be expected from these upper levels. If this were not the case, if the lower limits of the ore bodies were indefinite the Cobalt stock market would be in a very different state. The output this year must be practically at the summit and we may expect either no further increase or more probably a decline in annual returns, a decline which at the first will be gradual. The output of silver from Cobalt for 1911 probably exceeded sixteen and a half million dollars in value.

Gowganda, to a limited extent, is slowly recovering from its horrible wild-cat handling. Ore concentration is in steady operation, making regular shipments on a good pay ing basis. Steady progress with occasional shipments is be ing made on two or three other properties. Besides these there are several good prospects in this district which may ultimately be saved out of the wreckage. Other camps in the Elk Lake district are quiet.

With a gold camp the conditions are different. It is not a case of shipping a high-grade ore to smelters, but rather a treatment at the mine of a comparatively low-grade ore. This calls for extensive plant which takes money and time to build. As the plant is almost without value when the mine is exhausted, it is a business-like policy to make sure of the quantity and quality of the available ore before commencing work on a reduction plant.

In Porcupine during the past year progress has been remarkable for its character and its extent. Porcupine has done this for Ontario—it has caused experienced miners and mining financiers to flock to the district as they never did before in Ontario. The result is that the district is being properly explored and developed. It is true there have been and are wild-cats, some very rotten ones and some very ordinary, but these are unavoidable. The more important properties are being well handled and there are results to show for the money expended. The awful fires of the summer delayed work, caused a pitiful loss of life and a rather serious loss of money, but the camp itself is in many ways better off on account of it. The fire disaster checked a flaring promotion boom that would have done much harm to the mining industry.

The only gold produced to date has been from small tentative mills. The spring and early summer will see the beginnings of a steady and growing output. Two large mills, to cost when completed, more than half a million dollars, are being erected. Several smaller ones are under construction or have been ordered.

There are several certain successes in the camp and these all lie within a comparatively small area. Outside of this limited area there are many good probabilities and possibilities over a wide section of country, a section that grows as exploration work extends.

Geology has no bad news for Porcupine as it had for Cobalt. The limiting depth to which values will extend is indeterminate. This does not mean that the values will of necessity continue to go down indefinitely to great depths, it simply means that there are no reasons why they should continue or stop; it is a matter of chance just as are the extensions laterally, and the only way to settle the question is to go down and see.

The railway has now reached the heart of the district and this means much in many ways. There ought to be a healthy activity in the farming line, for there is much excellent land along the railway.

Swastika camp to the south-east of Porcupine is giving good promise on a smaller scale, and gold bearing quartz has been reported from many widely different points. Long before Porcupine was discovered it was truly said that there was more gold than silver in Ontario. Gold is scattered very widely, but only in a few localities had it been sufficiently concentrated to pay to work. Porcupine is one of these; there is no reason why there should not be more; the geological conditions are favorable over a wide extent of country.

Larder Lake is again attracting some attention. It has not yet recovered from the mishandling it got in its boom days. There is plenty of gold scattered over a large area in Larder Lake district, but it is hard to find a pay zone. It needs exploration by competent men.

Very interesting and satisfactory results are greeting the experienced men who are tackling some of the old mines and prospects in the Port Arthur district. The methods and men employed in the early days of this district might not only overlook good things but could easily blacken the chances of any good things they did uncover.

Ontario offers a fine field to the prospector. There are large accessible areas open to him. Cobalt and Porcupine show him the possibilities and there has never been time or place better for him in the way of making deals or getting assistance in his development work. On the other hand the absurd figures asked by prospectors for bare prospects have very materially held back some promising districts. The wild-cat promoter has set a fictitious value on prospects.

On the whole the silver and gold mining industry of Ontario is in a very healthy condition.

CONTRACTS FOR THE SUPPLY OF ELECTRIC POWER FROM THE POWER USER'S POINT OF VIEW.

III.

By H. E. M. Kensit, M.I.E.E.

We have now considered the matters of power factor and peak load and the methods of measuring them. (See previous article.) Other points in the same connection that should be provided for in drawing up a contract are as follows:

The power company usually requires a statement as to the maximum power that is likely to be required, in order that they may be prepared for all contingencies; also a guarantee as to the minimum amount that shall be paid for whether taken or not.

This minimum guarantee is reasonable, in that the power company must expend capital for generating plant and transmission lines to provide for the maximum, and must have some guarantee to justify the expenditure.

For the power company's benefit the probable peak load is usually estimated at a safe figure, and, on the other hand, the customer wishes to keep the guarantee as to minimum to be paid for as low as possible.

A margin of say 25 per cent. between the two is a fair business risk to the power company, especially as this risk is usually distributed amongst a number of customers, and the average result usually comes out better than anticipated owing to the growth of business and therefore of output and power taken.

This growth of business may necessitate the use of more power than the user would have felt justified in contracting for at the time of making the contract, and in the case of such contracts for a term of years, the customer should be protected as to any reasonable increase during the term of the contract.

The contract should therefore provide:—

(1) That the customer shall be allowed to exceed the agreed maximum amount of power to be taken by 10 per cent. without previous notice and at the same rate of charge.

(2) That additional power shall be furnished by the power company, under the terms and conditions of this contract, and at any time or times during the life thereof, up to the extent of a total of ..... horse-power, upon receipt by the power company of ..... months' notice in writing as to the additional power required.

The following are some sample clauses on these points from actual contracts:—

(1) "The power company agree to deliver ..... horse-power at the works of the customer by the ..... day of ..... and at the expiration of three months' written notice, which may be given at any time during the continuance of this agreement, to supply from time to time additional power in blocks of not less than ..... horse-power until the total amount so supplied shall amount to ..... horse-power.

"The customer agrees to pay for three-fourths of the amount so supplied or held in reserve whether he actually uses the same or not, and at no time to take more power than the amount so agreed upon and held in reserve by the power company."

(2) "The power company agrees to sell and deliver to the customer and the customer agrees to purchase and take from the power company for a period of ..... years from the ..... day of ..... electric energy to the amount of ..... electrical horse-power. It is further agreed that the power company will supply such additional power as may at any time be required over and above the amounts herein contracted for, and the cost of said power shall be on the same terms and at the same rates as for the amounts aforesaid."

(3) "The producer agrees to furnish continuously from the ..... day of ..... for ..... years, so far as reasonable diligence will enable it so to do, and for the operation of the consumer's industry only, not to exceed ..... horse-power of electric energy.

"The consumer agrees to pay the producer on the ..... day of each month for the energy furnished hereunder during the preceding calendar month, the sum of ..... dollars, and for additional energy taken by permission of the producer at the rate of ..... dollars per horse-power per month."

(4) "The producer agrees to furnish and the consumer agrees to take and pay for a minimum of ..... horse-power for the term of ..... years from noon on the ..... day of ..... The Consumer's maximum demand shall not exceed ..... horse-power without the written consent of the producer.

"The company will make every endeavor to supply any additional energy required, but it shall not be bound to do so upon less than six months' notice in writing, and in no case to supply more than it may have available and unsold from its then existing works."

A point of the first importance in regard to the measurement of the power used is the accuracy of the instruments when installed and their liability to get out of order afterwards. The instruments may have been supplied by a first-class firm and have been in perfect order and adjustment when they left the factory, but may be thrown out of adjustment in transportation or erection, or they may be wrongly connected, or influenced by magnetic fields in their vicinity, and the errors thus introduced may be quite large without the instruments giving any indication that would even lead to suspicion.

Experience has convinced the writer that no such instruments can be depended upon until they have been checked in position against standard instruments, and in his opinion this should be insisted upon as a condition of every contract. But even after this has been done the instruments are liable to alter as to their calibration or to get out of order from time to time, and it would be better still to provide that they should be re-checked in the same manner once a year. This is not an onerous condition. An electrical power company has usually and certainly ought to have the necessary portable standard instruments and can carry out such a test at small expense. Similar original and periodic tests are usually required by law in respect to house service meters, and are even more necessary for the large sums often involved in contracts for power.

Occasions, however, sometimes arise where the customer still has reason to doubt the accuracy of the meters, and is not satisfied to accept the check made by the power company, and to meet such cases it is usual to provide a clause that the customer may instal his own meters as a check and may require the power company to have their meters checked by an independent authority. This checking by an independent authority is expensive, and it is well to define by whom this expense is to be borne.

The following is suggested as a fair clause to cover the checking of meters, subject to modification to meet the conditions of each particular case.

"The necessary measuring instruments shall be installed and maintained by the power company, who shall, before using them as a basis of charge, furnish a satisfactory certificate that the said instruments have been calibrated in position against standard instruments, and who shall also

furnish to the customer tables or diagrams of the said calibrations.

"If requested in writing by the customer this calibration shall be repeated and diagrams furnished once in each year during the continuance of this contract.

"The customer shall be entitled to instal his own meters at his own expense as a check upon the power company's meters.

"The customer may at any time require the power company to have its meter or meters checked by an independent testing authority who shall be mutually agreed upon, or if there is failure to agree then the testing authority shall be named by ....., and on receipt of notice in writing from the customer that this test is desired the power company shall immediately have it carried out.

"Should such tests show the meter to be inaccurate by more than 2½ per cent. either way from absolute correctness over its working range, then the power company shall pay all the expenses of the test and shall adjust the current account for energy accordingly, but if the meter shall prove to be correct within the above limits, then the customer shall pay all the expenses of the test.

"Should the meter cease to record, then the charge shall be the same as that made for the previous corresponding period, plus, if necessary, an additional charge for any additional power used by any additional apparatus that the customer may have installed during the interval."

REPORT ON ELECTROLYSIS IN CHICAGO.

In the annual report of the Commissioner of Public Works of Chicago, just issued, is printed a report by Ray Palmer, consulting engineer, on the electrolytic damage to various underground metallic structures in different parts of the city caused by stray return current from the surface and elevated lines. Surveys made during August and September, 1911, showed excessive stray current in the neighborhood of the Illinois Street and Hill Avenue substations of the Chicago Railways Company, the Forty-second Street substation of the Chicago City Railways and at many points along the elevated railway structures.

The damage is said to include underground water pipes, lead cable sheaths, the metal in structural-steel buildings and the structural steel in bridges used by street railways in crossing the Chicago River. As a remedy for the conditions existing on the elevated structure the report recommends that large negative return cables should be placed on the structure and should be connected to the [illegible] at intervals of 300 ft. At the present time no return cables are used on any of the elevated structures in the city.

The existing city ordinance relating to the prevention of electrolysis is as follows:

"Ground return wires must be so arranged that the difference of potential between the grounded dynamo terminal and any point on the return circuit will not exceed 25 volts. The positive pole of the dynamo must be connected to the trolley line, and whenever pipes or other underground metal work are found to be electrically positive to the rails or surrounding earth, they must be connected by conductors arranged so as to prevent a flow of current from the pipes into the ground."

The report recommends that the ordinance be amended to read as follows:

"Ground return wire and rail circuits must be of such current-carrying capacity and so arranged that the difference of potential between any two points on the return will not exceed the limit of 12 volts. The railway companies must so equip their return current systems with insulated pilot wire circuits and voltmeters that an indicating reading may be obtained at any time showing the difference of potential between the negative busbars in each station and the extreme limits of the return circuit in the corresponding feeding district.

"The railway companies must protect all metallic work from electrolysis by the proper installation of a system equal to or better than a pipe and cable sheath drainage system consisting of insulated copper wires, pipe straps, ammeters, etc., which limits the maximum amperes drained from this subsurface metallic work to 10 per cent. of the total output of the station."

To operate within the limits required by such an amended ordinance the railway companies would be compelled to make one or more of the following improvements:

(a) Reconstruct all defective track work and install additional return feeders.

(b) Install a negative booster system.

(c) Install a return-current drainage system.

(d) Reduce the size of the power plant and substation feeding districts.

(e) Insulate the railway return circuits.

The report states that the most practical and efficient method of reducing electrolytic damage would be the installation of a pipe-drainage system. It recommends that all track bonds should be repaired and maintained in an efficient condition.

LONDON TRAMWAY AND GENERATING STATION.

The London County Council was constituted under the Local Government Act of 1888, its administrative area being over 120 square miles, and including some of the most populous portions of the Empire.

Probably no single authority has ever before exercised so many diverse functions as the London County Council, for it enters into practically every social activity of the London citizen from the cradle to the grave, handling anything from transportation to hotels.

The committee responsible for the control of the London tramway system is the Highways Committee, and this portion of the council's activities are principally dealt with in this article.

What is known as the London County Council Tramways consists of what was formerly a number of independent tramway undertakings operating within the county of London, together with certain new lines subsequently built by the council. Each of these companies owned from four to fifty miles of line, but gradually the council has taken over by purchase all the tramway companies within its area. The first transfer took place in 1895 and the last in 1909.

At the end of March, 1910, the system extended over 135½ street miles, of which 115½ miles were electric lines. The remaining 20 miles were at that time still worked by horse traction, but the latter have now practically all been converted to electricity.

The following table indicates the progress which has been made with the work of electrification. In some years it will be observed that while the amount of electrified lines increased, the length of horse lines also increased. This is accounted for by the acquisition by the council of other tramway undertakings.

Street mileage at end of year.	Electric traction in operation. Street miles.	Horse traction incld. lines in process of reconstruction. Street miles.	Total. Street miles.
March 31, 1904.....	19¼	69⅜	88⅝
March 31, 1905.....	26⅝	68¾	95⅜
March 31, 1906.....	30⅜	73⅝	104
March 31, 1907.....	58⅞	57⅞	116¾
March 31, 1908.....	68⅝	51¾	120⅜
March 31, 1909.....	84⅜	54⅛	129½
March 31, 1910.....	115½	20	135½

The above figures are indicative of the victory won by electricity over every other form of power, during the last 20 years. That unhappy animal, the tramway horse, meandered on its way for some time after experiments in electric traction had proved the infinite superiority of electricity, but the horse trams with their innumerable stops, delays, and inconvenience, at last proved intolerable and once the first step in electric driving was taken the rest was easy. A few horse trams are still to be seen in some outlying districts, but for all practical purposes the route is complete. Even in those busy parts of the Metropolis, where tramways are not allowed, the service is very largely carried out by motor omnibuses.

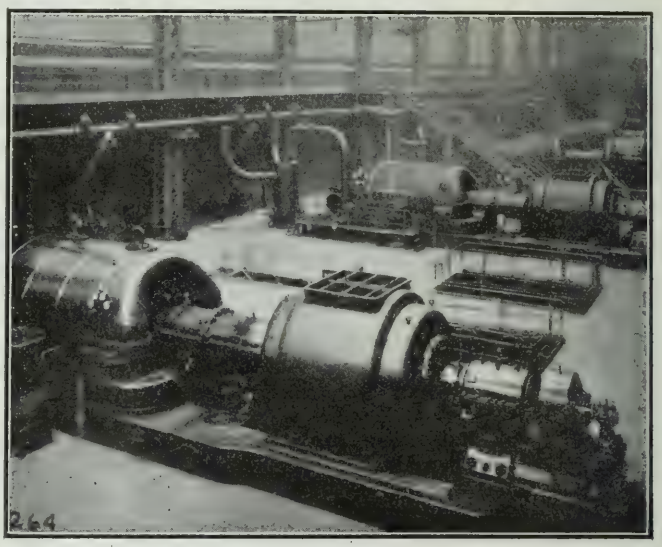
The total capital outlay of the London County Council Tramways amounted on the 31st March last to about $50,000,000. A report recently presented to the council, showing the results of the year's working during 1909-1910, gave the gross receipts of about $10,125,000 on the horse lines, viz., approximately $225,000, leaving a net surplus after payment on interest on capital outlay and for replacement of debt, of $960,000. The number of car miles run was 42,160,186, and the number of passengers carried 451,439,216.

The growth of traffic has arisen not merely from the increased mileage but also from the increase in the length of the routes electrified. Horse cars have only a small carrying capacity, and low-speed, and in London they are entirely at the mercy of the competition of motor omnibuses. Hence electrification in London has produced even more startling increases in the number of passengers than is the case in other towns.

Generating Station.—The electric generating station for the whole of London is situated at Greenwich, close to the River Thames. It was erected in two sections, and the site covers an area of approximately 3¾ acres.

The plant includes four vertical horizontal reciprocating engines coupled to three-phase alternators, of 3,000 kw. capacity each, four three-phase turbo alternators of 5,000 kw. capacity.

Two of the latter have only recently been installed. They were manufactured by the British Westinghouse Electric & Manufacturing Company, Limited, of Trafford Park, Manchester. An illustration of one of these sets appears below



5,000 kw. Turbo Alternator Sets Installed at Greenwich Power Station.

The two sets each comprise one 5,000 kw. 750 r.p.m. high pressure Westinghouse impulse type turbine coupled to one 5,000 kw. three-phase, 25-per., 6,600-volt, alternator, complete with Leblanc surface condensing plant and Leblanc auxiliaries.

The official tests of No. 7 turbine took place on the 8th, 11th and 13th January, 1911, after it had been eight months in regular service, with the results given below.

The guaranteed conditions were: Steam pressure, 180 lbs. per sq. in., with 120° F. superheat, vacuum 28½ inches (barometer 30 inches.)

No. 7 Set.

	25% Over-Load.	Full Load.	¾ Load.	½ Load.	¼ Load.
Test load in kws.....	6150	5165	3840	2572	1297
Guaranteed consumption..	——	14.5	14.75	16.0	19.5
Consumption obtained ..	14.74	14.30	14.60	15.67	19.31

This turbine has recently been opened for inspection after having been in operation for over 12 months, and it is found that the closest examination shows no trace whatever of erosion or corrosion, the blading being perfectly clean.

The normal plant capacity of the Greenwich generating station is 34,000 kw. The current is generated at a pressure of 6,600 volts, and is conveyed to various sub-stations over the tramway area.

The substations are provided with motor generators and rotary converters of a total capacity of 45,750 kw. transforming the current from alternating to direct at a pressure of from 550 to 600 volts.

The current is sent in the usual way from low tension switchboard through feeder cables which feed into the conductor rails in the conduit at half-mile intervals. On the over-head wire section the usual feeding arrangements for trolley wires are in use. The switches on the feeder panels in the sub-stations allow of the conductor bars in the conduit being changed so that either may be positive or negative, as required for the purpose of dealing with leakages to earth.

RAILROAD CONSTRUCTION THIS YEAR.

While about 2,000 miles of new railroad were built in Canada last year, the outlook for the present year is that as much if not more mileage will be added to the total. At the end of 1910, we had 24,730 miles. Last year the figures increased to approximately 26,500.

Sir Thomas Shaughnessy states that his road will probably build between 500 and 600 miles of new track this year and for an indefinite period. The main line from Medicine Hat westward for 534 miles is to be double tracked.

STEEL AS A TOWN BUILDER.
Canadian Northern Railway entering Stettler, Alberta, another link in Canada's transportation chain of 25,000 miles.

The contemplated construction on the Grand Trunk Pacific during 1912 is as follows:—

	Miles.
Main line	200
Brandon branches	16
Canora North	30
Regina boundary	155
Regina-Moose Jaw	45
Moose Jaw Northwest	50
Prince Albert	44
Battleford	48
Cut Knife	50
Biggar-Calgary	200
Alberta Coal	50
Mountain Park Coal	32
Melville to Watrous	75
Weyburn	60
Calgary to Coutts	50

The contract for five million dollars' worth of construction work in British Columbia for the Canadian Northern Railway was awarded to one firm who state that there is probably more railroad building going on in British Columbia than in any other part of the Dominion or the United States. They will begin active construction work on the new contract next spring. The plans call for 100 miles of road beginning about 50 miles above Kamloops, up north along the Thompson River Valley. When that is finished the Transcontinental chain of the Canadian Northern Railway will be practically completed.

Construction will commence on the Canadian Northern line from Toronto to Hamilton next spring.

The Canadian Pacific Railway is asking for parliamentary authority to construct new lines in Saskatchewan and Alberta. The Canadian Northern are seeking powers to build lines in the Peace River District, Alberta.

A large number of new railroad schemes are in the "charter" stage.

OUTLOOK IN ONTARIO MINING DEVELOPMENT.

By Thos. W. Gibson, Deputy Minister of Mines, Ontario.

During the past few years the advance in the mineral production of Ontario has been rapid, as the following figures show:—

Year.	Value of production.
1905	$17,854,296
1906	22,388,383
1907	25,019,373
1908	25,637,617
1909	32,981,375
1910	39,313,895

The statistician is rarely justified in venturing on the realm of prophecy, but the upward tendency of the curve described by the growth of mining in Ontario points strongly to still greater things in the future. It can hardly be doubted that the extension of prospecting into northern Ontario, now being rendered possible through railway construction, will bring to light new mineral fields probably as rich as any that have yet been found. The discovery of one such field leads almost as by a law of nature to the discovery of others. Silver Islet led to Rabbit Mountain and Beaver; Copper Cliff and Stobie to Creighton and Crean Hill and Garson; the Helen mine to the Josephine and Magpie; Sultana to Mikado; Cobalt to South Lorrain and Gowganda, and latest of all to Porcupine. Nor do the pre-Cambrian formations possess a monoply of mineral wealth; the Devonian and Silurian strata of southwestern Ontario have for years yielded goodly supplies of petroleum, natural gas, salt and gypsum. Petroleum may be declining in production, but that there are reservoirs, great or small, yet untouched, seems to be shown by the striking of oil in paying quantities a short time ago in Onondaga township, and the field for profitable production of natural gas appears to be steadily widening until it promises to cover a large part, if not the whole, of the northern and eastern shores of lake Erie. These stratified rocks have their counterparts on the slope leading down to James bay. Already gypsum in large deposits has been located there, and it would seem not unreasonable to entertain the hope that the future inhabitants of the clay belt north of the height of land may find it possible to light their homes with oil, cook their food with natural gas, and cure their pork with salt, all derived from the rocks underlying the farms from which they harvest their crops.

IRRIGATION BY PUMPING.*

By H. J. Kennedy.

In the development of an irrigated country, the lands first irrigated are naturally those which can be reached by gravity ditches; as these become settled and land values increase there comes a point where it pays to pump water on to lands lying too high to be reached by gravity flow. In irrigation by pumping, the efficiency of the use of water capacity takes on an added importance, for pumping is expensive, and the higher the irrigation duty obtained from a unit of water, the more land can be irrigated with a plant of given capacity and with a given power consumption.

As an instance of duty under a pumping system may be mentioned a certain large district in the interior of Washington, for which experts have concluded a rate of water pumped of 0.007 cu. ft. per second per acre, or 143 acres per second-foot, to be a reasonable amount. If 10 per cent. of this be lost by seepage and evaporation, the rate of application at the land becomes 0.0063 sec-ft. per acre, 4.5 acre-ins. per month, or 158.7 acres per sec-ft. But of course what is a fair allowance under some conditions of soil and drainage may be a great excess in others.

The next consideration when seeeking pumping economy is to reduce the unit cost of power as low as possible. This is attained by using apparatus of high efficiency, or by using cheap sources of power, or both. Falling water, in modern times as of old, furnishes a highly appreciated source of power. Quite a number of water power developments for irrigation pumping have been made or projected, both on large and small scales.

As examples of the large ones may be mentioned, in California the extensive system of the Mt. Whitney Power Company, comprising four power stations, on the Kaweah and Tule Rivers, which flow from the Sierras into the San Joaquin Valley, and a steam auxiliary generating plant; the total capacity of these plants is 8,850 kilowatts, which is conveyed by a network of transmission lines and utilized chiefly in pumping water by plants scattered throughout the valley, the area watered at present being about 18,000 acres.

In Idaho the power development at the diversion dam of the Minidoka project on the Snake River, the total capacity being divided into five generating units of 1,200 k.w. each, the irregular area under the pumping system being 49,900 acres.

In Washington a fraction of the 90,000 horse-power available on the great Columbia River at Priest Rapids has been developed by the Hanford Irrgation & Power Company, and utilized for pumping water from a different point on the same river to about 16,000 acres of land on the plateau above the river. This is an interesting example of private enterprise going into a region which was nothing but a vast treeless desert with a big river flowing through its midst and no population to speak of; putting the forces of nature to work and developing a new country out of the desert. It is still new and some particulars may well be included here.

The Hanford Power and Pumping Development.—The property has recently been taken over by the American Power & Light Company, but is still best known locally as the Hanford plant. The first generating unit was installed in 1909 and the second in 1910.

The Priest Rapids power station was designed for a present capacity of 2,600 horse-power, but provision was made for an ultimate development of 9,800 horse-power, with a minimum head of 18 ft. The maximum head reached, at high water, is 27 ft. The power house is of reinforced concrete, and has had installed in it two generating units, consisting of vertical-shaft turbines direct-connected to generators on the floor above. Each of the two shafts carries three turbine runners; the speed at 18 ft. head is 150 r.p.m. Each of the generators is a 900 k.w. three-phase, 60-cycle, 2,300-volt, revolving-field alternator. There is an exciter driven by a separate turbine, and another driven by an induction motor. The potential is stepped up by oil-filled, water-cooled transformers to 22,000 volts for the transmission line, which is 16.3 miles long, and which delivers the current to the pumping station at Coyote Rapids farther down the river.

The pumping station is of similar construction to the power station, and has room for four pumping units, two of which are at present installed. Like the generating units, these are vertical-shaft direct-connected, the induction motors being on the upper floor and the centrifugal pumps down below. Each motor is 450 horse-power, three-phase, 60-cycle, 2,200-volt, 175 r.p.m., the line potential being stepped down by transformers similar to those in the power station; half-voltage taps are provided for starting the motors.

Each pump is a single-stage, vertical-shaft, single-suction, enclosed-runner, centrifugal pump, designed for 62.5 sec-ft. capacity against a total head of 50 ft., with 30-in. suction connection and 30-in. discharge. The water from the two pumps enters a single delivery pipe of 66-ins. diameter, discharging into a cement-lined basin at the head of the main canal. The Allis-Chalmers Company, who built and installed the machinery and apparatus in these plants, guaranteed the pumps to have an efficiency of 65 per cent.

Utilization of the Power at Drops in Laterals.—The use of water-power for pumping is not, however, dependent upon the presence of big rivers and waterfalls where thousands of kilowatts run to waste. An extensive irrigation system may be run through a country in which the land is generally quite flat, but where, nevertheless, the topography is broken in some places; or it may be in a region abounding in steep places. In either case there will be points where the most direct location of canal or lateral will give a grade too steep for an earthen ditch, because of the erosion of the banks from the swiftly flowing water. This necessitates the use of drops. Sometimes a drop is in principle just like a timber or concrete dam; sometimes it is a conduit, open or closed, or merely a stream or waterfall down a rocky hillside; in any case there is a quantity of water falling a certain height in a reasonably short horizontal distance, constituting a water-power. With power going to waste in the system this way, and with areas of high land which could be irrigated by pumping, it is natural to study whether it will pay to make the necessary outlay and use the source to fill the need.

An example from actual practice will illustrate this kind of problem. Consider two drops in different laterals, situated a few miles apart; the former can be called A and the latter B. At drop A the water flows first through a wooden trough, then over the rocks where the surface soil has been eroded; total fall 75 ft. in a horizontal distance of 460 ft. At drop B there is four times as much water, but only about 21 ft. fall. Drop A is a natural one, drop B is entirely artificial, the deep excavation forming a channel which for a long distance has no outlets and lies much below the level of the surrounding country. There are thousands of acres of dry land in the vicinity, higher than the main canal, having good volcanic ash soil, and needing only water to become valuable agricultural land. The main canal carries plenty of water. Now having power, water and dry land, what can best be done.

* Abstracted from an article in the "Purdue Engineering Review" for 1911.

We get up a preliminary design consisting of the following elements: A hydro-electric power plant at drop A; an electrical transmission line from there to drop B; hydraulic power development at power B; pumps at drop B driven by the transmitted electric power and by the hydraulic turbine. On the way over the transmission line is tapped to supply power to a pumping plant for an isolated high tract.

The electric power plant to be located at the foot of drop A would contain a turbine direct-connected to a three-phase alternating current generator. Concrete headworks at the top of the drop and a steel penstock would be provided to convey the water to the turbine. A by-pass must also be provided to supply lands below the drop in case the turbine is shut off.

The current can be transmitted this distance without step-up transformers, making the generator potential 2,300 volts. At drop B we can utilize the current in an induction motor at the line potential.

Starting with the horse-power available from the drops, and figuring the thing out step by step, allowing for the various hydraulic, mechanical and electrical losses, we come to the problem of determining the proper combination of height of lift and quantity of water pumped to make use of the power to the best advantage. There are in the problem several varying elements, as follows:

(a) Area of land between any selected contour line and the canal from which the water will be pumped.

(b) Quantity of water which can be pumped by the given horse-power to any selected height of lift.

(c) Number of acres which can be irrigated by the given horse-power at a given rate of duty, for any selected lift.

(d) Number of acres which can be irrigated by any selected quantity at the given duty.

The writer has applied with very satisfactory results a graphical method of solution previously used in this class of problem by Mr. E. A. Moritz, C.E. Figure 1 is a diagram for the simplest possible case, viz., a single lift and single district irrigated. Taking the total brake horse-power available at the site of the pumping station, and allowing a certain percentage for losses in pumps and delivery line, we get, say 156 net horse-power in water pumped, equal quantity pumped, in second-feet, multiplied by height of lift in feet and divided by 8.8 practically.

From a topographical map of the land above the canal, we obtain the areas between the various contour lines (which may be selected for discharge elevations) and the canal, by measurement with a planimeter, and plot them as a curve in which the abscissae represent acres and the ordinates represent height of lift, or difference of elevation between outlet contour and main canal, on line of proposed discharge pipe. In this case the slope of the land averaged up so nearly uniform that the portion of the curve plotted is shown as a straight line, marked A.

Curve B is also plotted with reference to lift on the vertical scale, but its abscissas represent the quantity of water which can be pumped at various lifts, as obtained from the foregoing equation. It is obvious that the curve will be an equilateral hyperbola.

A third curve, marked C, is plotted with reference to lifts; it is derived from B by multiplying the quantity pumped at any lift by the duty, or number of acres per second foot, in this case assumed at 143. It will, therefore, also be a hyperbola and will show acres of abscissas.

Finally, the different values of "water pumped," as shown on the horizontal scale, are multiplied by the constant duty (143), giving number of acres corresponding to each quantity pumped, at the given duty, and the resulting straight line D is drawn, acres being in this case ordinates, since the abscissas have already been used for quantity of water.

A and C intersect at a lift of 60.5 ft., and an acreage, read on the horizontal scale, of 3,250. The corresponding quantity pumped is found by running horizontally along the 60.5 ft. level to curve B, as indicated by the dotted line, which intersects B at value 22.8 cu. ft. per second. If now the dotted line be followed vertically downward to intersection with line D, we read on the vertical scale the acreage irrigable by this quantity, 3,250 acres, checking with the value read at the first intersection and demonstrating the accuracy of the work.

This diagram may become quite complicated if plans for using two or more lifts be considered, necessitating

Fig. 1.

division of the horse-power into units and plotting separate curves B and C for each unit; and if different values of water duty be considered, the number of curves C and D plotted will be multiplied by the number of duty values considered. In such a case one would use a color scheme. The principle is sufficiently illustrated by the simple case chosen, without going into such complications, and it is evident that a great deal of figuring can be saved as compared with a cut-and-dry method of solution.

Having ascertained from the diagram the height of lift, computations can be made as to quantity pumped per unit, proper sizes of pipe, etc., and the selection of types, sizes and speeds of motors, pumps and turbines best adapted to the work and to each other is made. Making general plans for the setting and housing of the machinery, and an esti-

mate of construction cost of the different plants with their machinery, the transmission line, pipe lines and water distribution systems, and dividing by the number of irrigable acres, will give the charge per acre for first cost; the estimated cost of operation is divided in like manner. Statistics as to crop values and net profits per acre from similar lands already under cultivation in the neighborhood, will permit a comparison of the cost of the proposed improvement with the ability of farmers to stand the cost.

A preliminary design made by the writer for a pumping plant operated by hydraulic and electric power, is shown by Fig. 2. In this design the aim was substantital construction, with small maintenance cost, together with convenience and accessibility. It provides for concrete headworks and flash-board supports on the main canal, the cross-section of which is reduced as it passes the branch canal, at the head

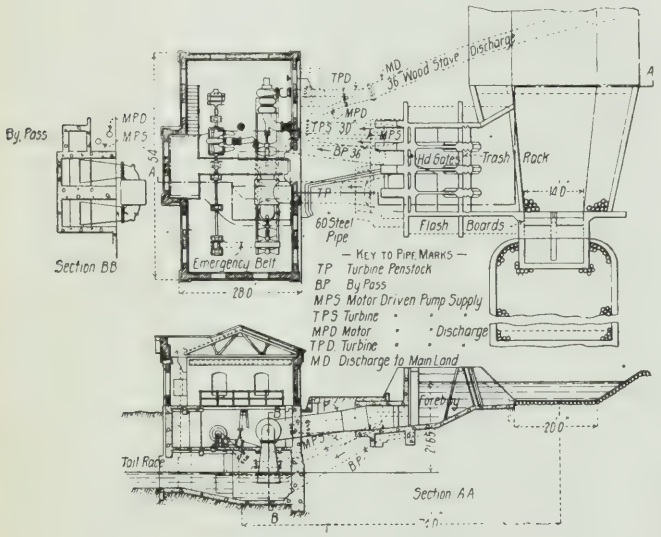

Fig. 2.

of which the plant could be located. The water goes through the trash racks, through the forebay (above which is to be carried a road which parallels the main canal), and through the head-gates to the various pipes. There are two gates supplying the turbine penstock; one gate supplying by-pass, feeding water to the branch canal if turbine is not discharging the necessary amount; and one gate supplying the pumps.

The turbine speed at the given head is so low as to require either very large pump impeller, or a multi-stage pump, to raise the water to the proper height. The motor-driven pump, however, can be a single-stage, because of the ample speed of the motor. Aside from other advantages, the centrifugal type of pump is particularly adapted to this service, because of the large amount of silt carried by the water in this canal.

In case of accident to the electric supply or apparatus, the turbine would be the sole motive power. The emergency belt connections shown makes it possible in such an event, to use either pump and shut off the other for repairs or other necessary attention. When not in use, the belt and shafting do not waste any power in friction as provisio is made for disconnecting them at the couplings.

As a considerable portion of the excavation at the site is already made, the excavation cost for this plant would not be as great as might appear from the drawing.

Greater compactness of the plant might be attained, at the sacrifice of certain features which it was desired to embody in this design. It should also be borne in mind that this does not represent a final, perfected design, but is merely a preliminary plan.

LABORATORY METHOD OF OBTAINING CORRECT PROPORTION OF PORTLAND CEMENT TO SAND OR STONE SCREENINGS FOR MORTAR.

That chemistry is a great help in matters pertaining to the manufacture of cement is a well-known fact, but that precise chemical methods may be used in concrete proportions is a fact not so generally known. The ideal or theoretically perfect concrete is that in which the best aggregates are scientifically proportioned and graded in size so as to reduce the percentage of voids to the minimum and give the greatest density. According to Mr. Albert Moyer, Asso. Am. Soc. C.E., who has spent considerable time in expedimental work along this line for the Vulcanite Portland Cement Company, Philadelphia, Pa., U.S.A., it is convenient to assume a weight of 94 pounds net (1 bag of Portland cement) to the cubic foot, and allow 2 42/64 oz. of cement to the 50 c.c.

The necessary equipment includes several graduated glass tubes of 200 or 250 cubic centimeters capacity and a balance that is sensitive to a sixty-fourth of an ounce (6 grains).

Weigh several samples of cement of 2 42/64 (50 c.c.) each. Measure several samples of sand from 87.5 to 150 c.c. each, so that proportions of cement to sand are secured thus, 1:1.75, 1:2, 1:2.25, 1:2.5, 1:2.75, 1:3.

The sand should be dried before measuring, which should be done accurately; pour the dry sand slowly into the measuring tube, jarring the same while pouring. Add the previously weighed cement sample to the sand, and then add sufficient water to make a mortar which, when tamped in the glass tube, will not cause any water to rise to the surface.

Place a little of this mortar at a time in the graduated glass tube (not over 4 c.c. at one time). Press the mortar down hard with a flat-end stick, leaving enough space for the expulsion of air between the walls of the tube and the stick. Pack the mortar as tightly as possible and note the space occupied by each sample. It will be found that the total volume of any one sample will exceed the space occupied by the sand alone.

The sample containing maximum density will be that which contains (in progression) the largest amount of sand but has not appreciably increased the volume of the mortar. As an example, supposing it to be found by this method that the sample containing proportions of 1:3 gave a volume of 110 c.c., 1:2.75 gave 110 c.c., 1:2.5 gave 110, and 1:2.25 gave 115 c.c. Then, the 1:2.5 is the sample which should theoretically give maximum density of the mortar. The 1:2.25 would be too rich, and the 1:3 too lean.

The cement having been weighed in each instance the unit of measurement for the cement being 94 lbs., 1 bag of cement assumed to be equivalent to 1 cu. ft., calculated on the actual volume of a barrel of cement as being 3.8 cu. ft. —the quantity of sand being measured and noted for each sample, you are thus in possession of the proportions required for a mortar for use in actual work. This refers entirely to concrete in which maximum density is required; such concrete will be almost impervious to water.

Having obtained the volume of mortar produced by each sample and the tensile strength of each sample, you can then determine as to whether a mortar of less density may with safety be used for work which does not require a water-tight concrete.

In the matter of screenings or quarry tailings for mortar, all of which will pass through a ¼-inch sieve and not containing over 10 per cent. of dust—that which would pass

through a 100 sieve—you may obtain the proportion of cement to screenings or quarry tailings which will produce maximum density, in the same manner, with the possible exception that a larger diameter graduated glass tube should be used on account of the shape of the particles of the quarry tailings.

By the method above described the relation of weight to volume is standard, these figures being based on 94 lbs. of cement as being equal to 1 cu. ft. Therefore, it makes no difference whatever if this be actual or not. Thus the variations in different brands of cement are automatically cared for, providing the same brand is used to determine the proportions for mortar as will be used in the actual work. These tests should be carried on with various sands, as there may be two or more sands obtainable in the same locality, one of which might require much less cement than the other and yet obtain maximum density in the mortar, effecting considerable economy on a large job.

THE ADHERENCE OF FLAT SURFACES.

A paper on the "Adherence of Flat Surfaces" was read before the Royal Society by Mr. H. M. Budgett, who remarked that in recent years it has been found possible to polish plane surfaces of hardened steel to a degree of accuracy which had previously been approached only in the finest optical work, and to produce steel blocks in the form of end gauges which can be made to adhere or "wring" together in combinations. These blocks will often cling together with such tenacity that a far greater force must be employed to separate them than would be required if the adhesion were solely due to atmospheric pressure, and the purpose of the paper was to examine the various causes which produce this adhesion.

The only previous experiments in this direction appeared, he said, to be those carried out with Whitworth surface plates by Professor Tyndall in 1875. By wringing together two of these plates and suspending them in a vacuum, he proved that the adherence between them was not caused solely by atmospheric pressure, as had been previously supposed. According to Goodeve, the conclusion at which Tyndall arrived was that the plates adhered by the molecular attraction of the bearing points brought into close contact by reason of the near approach to absolute truth of surface. Frequent references had been made to these experiments, and the conclusions of Tyndall appeared to have been generally accepted.

Liquid Films.—The author's curiosity was aroused by the fact that some steel gauges which he was constantly using in combinations did not always cling together with the same force. Frequently they refused to adhere to one another at all, whilst at other times considerable difficulty was experienced in getting them apart. On one occasion, when two blocks had been left wrung together for a long time, it was found necessary to hold one in a vice and hit the other sharply with a hammer in order to separate them. Subsequent examination showed that the faces had rusted together, which proved that some moisture must originally have been present between them. This led to the discovery that a minute film of condensed water vapor always formed upon the steel when the blocks were held with warm hands, and if care were taken to avoid this, and the faces were thoroughly cleaned with alcohol to remove grease, then all signs of adhesion vanished and the blocks would fall apart at once under their own weight. It soon became clear that the wringing effect was chiefly due to the presence of a liquid film between the blocks, and it was decided to make a series of experiments in order to examine the adhesive properties of various liquid films, the effects of atmospheric pressure, and the force of attraction between the molecules of steel in the two surfaces.

A number of hardened steel blocks were specially made in the form of cylinders 1 in. in diameter and ½ in. deep, having a central screwed hole 5/16 in. in diameter, the area of the faces being thus 0.7 sq. in. These were specially polished with great care so that their faces were true planes within one-millionth of an inch, the accuracy being optically tested by means of proof glasses. Many hundreds of readings were taken with dozen of pairs of blocks, and the average and maximum results were given in the following table:

Liquid.	Pull in lb. at separation.	
	Average.	Maximum.
Condensed water vapor	35	65
Turpentine	29	39
Paraffin	27	46
Oil of almonds	24	35
Lubricating oil (Price's)	22	30
Olive oil	20	33
Sperm oil	18	32
Rangoon oil (Price's)	17	28

Considerable variation in the readings was unavoidable, as it was impossible to gauge exactly the thickness and uniformity of the applied films, and there was an element of uncertainty in the action of sliding the blocks together. No adhesion could be obtained with volatile liquids such as alcohol, benzine, and petrol, and viscous liquids such as glycerine, treacle, and glucose produced very little effect.

Atmospheric Pressure.—In order to determine what were the effects of atmospheric pressure, arrangements were made by which, after being wrung together, the blocks could be separated in a vacuum. It was surprising to note that the force due to atmospheric pressure in no case exceeded 5 lb., as, the area of the faces being 0.7 sq. in., it might have been expected that this force would have approached 10.5 lb. It might naturally be supposed that such accurate surfaces, with a grease film between them, would be perfectly air-tight. It was evident, however, that air must have free access to a very large area of the faces, probably owing to the blocks being pulled apart or distorted slightly under the strain of the applied force, the film between them stretching before breakage occurred. It must be remembered that the volume required to fill the space between the faces was exceedingly minute, and since the pull was increased very gradually, a considerable time was allowed for the air to leak in or out. With thicker films the atmospheric pressure had a greater effect. Thus, with a fairly thick layer of Rangoon oil a difference of 6.5 lb. was noted between the force of separation in air and in vacuo, the force due to the air in this case being 9.3 lb. per sq. in. This might be due to the air being more impeded by the thick oil, or to the faces being less distorted, or separated, owing to a smaller force being required to cause breakage when a thick film was present. On the other hand, when the faces were perfectly clean and no film whatever was present, the adhesion almost vanished and the blocks would not support each other although their weight was only 1½ oz., showing that in this case the force due to atmospheric pressure was almost eliminated. For the same reason it was obvious that the force due to the attraction of the molecules of steel in the opposing faces was quite negligible in comparison with those under consideration.

The author concluded that at least 75 per cent. of the adhesion was caused by the presence of a liquid film between the faces in contact, and that not more than 25 per cent. was due to atmospheric pressure.

Metallurgical Comment

Correspondence and Discussion Invited

PRODUCTION OF IRON AND STEEL IN CANADA.*

The iron and steel industry in Canada has had a fairly steady and continued development during the past few years. The serious depression under which this industry suffered in the United States in 1908 had comparatively little effect in Canada although there was a general falling off in output during the year. The production of 1909, however, greatly exceeded that of 1907, while the year 1910 again shows a very substantial increase in the production of pig iron and steel over the year 1909. The actual shipments of iron ore, however, from Canadian mines in 1910, were less than in 1909, although greater than the 1908 shipments.

The total shipments of iron ore from mines in Canada in 1910 were 259,418 short tons; there were used in blast furnaces 1,548,226 tons of iron ore, and in steel furnaces 39,332 tons; 800,797 tons pig iron were made, a large part of which was used directly in the manufacture of steel, and a total of 822,284 tons steel ingots and castings were made.

The development of iron ore mining in Canada has not kept pace with the growth of the metallurgical industry in iron and steel. The rate of production of iron ore has shown practically no increase during the past ten years, while the production of pig iron during the same period has increased nearly eight fold.

About 11 per cent., only, of the iron ore used in Canadian blast furnaces during 1910, was of domestic origin; of the coke used 49 per cent. was either imported or made from imported coal, and 18 per cent. of the limestone flux used was from sources outside of Canada. It is evident that this industry is now to a very large extent dependent upon imported raw materials.

The assistance granted by the Federal Government to the iron and steel industries in the form of bounties, ceased on December 31, 1910, with the exception of the bounty on steel rods, which was continued to June 30, 1911.

The accompanying table gives a summary of the chief statistics of production of iron ore, pig iron, and steel, while more detailed records will be found in subsequent pages:

Summary of Iron and Steel Statistics 1908, 1909, and 1910.

	1908. Tons.	1909. Tons.	1910. Tons.
Iron ore shipped	238,082	268,043	259,418
Canadian iron ore charged to blast furnaces	209,266	257,502	171,191
Imported iron ore charged to blast furnaces	1,051,445	1,235,000	1,377,035
Iron ore charged to steel furnaces	(a)	(a)	39,332
Pig iron made	630,835	757,162	800,797

(c) Figures cover the calendar year.

(d) Figures cover the fiscal year ending March 31.

IRON ORE.

The total shipments of iron ore from mines in Canada in 1910 were 259,418 tons valued at $574,362 at the shipment point, as compared with 268,043 tons valued at $659,316 in 1909, and 238,082 tons valued at $568,189 in 1908. Of the 1910 production 130,380 tons are classed as hematite, 127,768 as magnetite, and 1,270 tons as bog ore. Ontario is the largest producer, having shipped 231,445 tons or nearly 90 per cent. of the total production. New Brunswick enters the list of producers with shipments of 5,336 tons from the mines near Bathurst. In Nova Scotia 18,134 tons were shipped from the Torbrook mines and in Quebec province, in addition to the bog ores, a small tonnage (3,233 tons) of titaniferous iron sands was shipped from the north shore of the St. Lawrence. Although no production of iron ore is credited to British Columbia, a shipment of a small barge load of copper was made from the Raven mine, Texada island, to Seattle, Wash.

The production by provinces during the past three years was as follows:—

Production of Iron Ore by Provinces, 1908-9-10.

Provinces.	1908. Tons.	1908. Value. $	1909. Tons.	1909. Value. $	1910. Tons.	1910. Value. $
New Bruns'k	.....	.....	.....	.....	5,336	11,910
Nova Scot'a.	11,802	17,620	.....	.....	18,134	40,478
Quebec	10,103	22,094	4,150	5,508	4,503	8,252
Ontario	216,177	528,475	263,893	653,808	231,445	513,722
British Colm.	.....	.....	.....	.....	.....	.....
	238,082	568,189	268,043	659,316	259,418	574,362

The production during 1909 and 1910 classed as magnetites (including titaniferous iron sands and some ores with an admixture of hematite), hematites (including brown ores), and bog ores, was as follows:—

Classified Production of Iron Ore, 1909-10.

Character of ore.	1909. Short Tons.	1909. Value. $	1909. Per Ton. $ c.	1910. Short Tons.	1910. Value. $	1910. Per Ton. $ c.
Magnetite	74,240	162,280	2 19	127,768	289,876	2 27
Hematite	190,473	492,348	2 58	130,380	281,090	2 16
Bog	3,330	4,688	1 41	1,270	3,402	2 68
	268,043	659,316	2 46	259,418	574,362	2 21

* Abstracted from Govt. Report.

Nova Scotia.—The Torbrook mines were the only shippers during 1910, the quantity shipped being 18,134 tons in three cargoes to Philadelphia, Pa., Glasgow, Scotland, and Middlesborough, England, respectively. The ore is a hematite and the shipments averaged about 48 per cent. metallic iron. The total quantity of ore mined during the year was 53,054 tons, a large part of which was in the stock piles at the mines at the close of the year.

Some development work was done at Arisaig, Antigonish county, by the Arisaig Iron Company, but no ore was shipped.

The blast furnaces at Sydney and North Sydney receive their ore supplies from Newfoundland chiefly. The two Canadian companies operating at Wabana, shipped during the year 1,259,626 short tons of hematite ore averaging fro n 50 to 52 per cent. iron; of which 808,762 tons were shipped to Sydney and 450,864 tons to the United States and Europe.

New Brunswick.—Shipments were made from the mines at Austin Brook, near Bathurst, to the extent of 5,336 tons, the ore being sent to Philadelphia. The ore is a magnetite with an intermixture of hematite, and the properties are being developed by the Canada Iron Corporation. About 25,515 tons of ore were mined during the year. Shipments are made from the company's docks at Newcastle, at which there was a considerable tonnage in stock at the close of the year.

Quebec.—The iron ore production in Quebec in 1910 included 1,270 tons of bog ore shipped to Drummondville, and 3,233 tons of titaniferous magnetic sands shipped from St. Urbain, Champlain county, to the United States. In 1909 the shipments were 3,330 tons of bog ores and about 820 tons of titaniferous iron sands.

These titaniferous sands have been shipped largely for experimental purposes and a nominal value of $1.50 per ton has been placed upon the production, although the actual cost of placing the ore on board vessels was possibly several times this amount.

Ontario.—Shipments were made by four mines in this province during the year, viz.: the Mayo, at Bessemer, Hastings county; the Moose Mountain, at Sellwood, 30 miles north of Sudbury; the Helen, north of Michipicoten, and the Atikokan, 130 miles northwest of Port Arthur, on the Canadian Northern Railway. In addition to these a considerable tonnage of ore was reported as having been raised at the Wilbur mine in Lanark county, but no shipments were made.

The total shipments of ore during the year were 231,445 tons, valued at $513,722; as compared with shipments of 263,893 tons, valued at $653,808, in 1909.

British Columbia.—No regular shipments of iron ore were reported from the province. Some prospecting work was done on the Raven mine on Texada island, and a small scow load of cupiferous iron ore shipped to Seattle, Wash., for experimental purposes.

Following is a list of the principal producers of iron ore in Canada:—

Canada Iron Corporation, Limited, Mark Fisher Bldg., Montreal.

E. H. Duval, Levis, Que. (Guay P. O.).

H. C. Bosse, 92 St. Peter St., Quebec, Que.

Joseph Bouchard, Baie St. Paul, Que.

The Canadian Iron Ore Co., 1231 St. Valier St., Quebec, Que.

Exploration Syndicate of Ontario, Limited, Wilbur, Ont.

The Lake Superior Power Company, Sault Ste. Marie, Ont.

Atikokan Iron Company, Port Arthur, Ont.

Moose Mountain, Limited, Sellwood, Ont.

Dominion Bessemer Ore Company, Limited, 472 Bullitt Bldg., Philadelphia, Pa.

Pig Iron and Steel.—An increase is shown in the production of pig iron in Canada in 1910 over the production of 1909, as compared with an increase of 20 per cent. in 1909 over that of 1908.

At the close of the year Canada had seventeen completed furnaces and two under construction, grouped in ten separate plants and operated by eight separate companies or corporations.

The Londonderry furnace was not in operation during either of the past two years. These figures do not include the output from electric furnaces making ferro-products which are situated at Welland and Sault Ste. Marie, Ont., and Buckingham, Que. Ferro-silicon was made at Welland during 1910, but the Sault Ste. Marie and Buckingham plants were not in operation during the year.

Of the total output of pig iron in 1910, 17,164 tons, valued at $333,956 or $19.78 per short ton, were made with charcoal as fuel, and 783,633 tons, valued at $10,911,674 or $13.92 per ton, with coke.

The classification of the production in 1910 according to the purpose for which it was intended was as follows:—

Bessemer 219,492 tons, basic 425,400 tons, foundry (including miscellaneous) 138,741 tons.

The total production of pig iron in 1910 and 1909 is shown by provinces in the following table, the average value per ton being also indicated. In the case of Nova Scotia a large proportion of the pig iron is directly converted to steel, and as a very small portion of the metal is sold as pig iron it is somewhat difficult to place a satisfactory valuation upon the output. For statistical purposes a value of $12 per short ton has been placed upon this production in 1910. The Quebec production is entirely charcoal iron, which has for many years commanded a high price.

Production of Pig Iron by Provinces, 1909-10.

Provinces.	1909. Tons.	1909. Value. $	1909. Value per ton. $	1910. Tons.	1910. Value. $	1910. Value per ton. $	Percentage increase or decrease in quantity. %

Total	757,162	9,581,864	12.65	800,797	11,245,622	14.04	+ 5.8

Of seventeen completed furnaces, six were in blast in 1910, for varying periods of time. The operating companies, with numbers and capacities of furnaces, were as follows:—

Dominion Iron & Steel Company, Sydney, C.B., one of the constituent companies of the Dominion Steel Corporation, Ltd.: four completed furnaces of 280 tons capacity each per day, operated throughout 1910, two for 365, one for 112 days, and the fourth for 255 days. A fifth furnace has been completed and will go into blast early in 1911, while the erection of a sixth furnace has been arranged for, the completion of which will give this company a capacity of over 400,000 tons per annum.

Nova Scotia Steel and Coal Company, Limited, New Glasgow, N.S.: one furnace at Sydney Mines, C.B., of 200 tons capacity, operated 311 days. Furnace was blown out on May 1, when, according to the report of the general manager, a new crucible jacket of 2½-inch plate, steel reinforced with cast-iron, water-cooled slabs 4½ inches thick, dovetailed into each other, new bosh jacket and mantel were installed; the furnace lined throughout, hot blast stoves, downcomers, gas-mains, boilers, blowing engines, and pumps were all overhauled and renewed where necessary. The furnace again went into blast June 24, and from this date to December 31, made an average daily output of 243 tons. For the same

period, previous to relining, the average daily output was 160 tons.

Londonderry Iron & Mining Company, Limited, Londonderry, N.S.: one furnace of 100 tons capacity; idle throughout the year.

Canada Iron Corporation, Limited, Montreal, Que.: two small furnaces of seven and eight tons capacity, at Drummondville, Que., operated 272 days; one furnace of 25 tons daily capacity, at Radnor Forges, Que., operated 41 days during 1910; two furnaces of 125 tons and 250 tons at Midland, Ont., operated for 7 months and 4 months respectively.

Standard Chemical Company of Toronto, Deseronto, Ont.: one furnace with a daily capacity of 50 tons, operated for 253 days, during 1910.

Hamilton Steel & Iron Company (now the Steel Company of Canada, Ltd.), Hamilton, Ont.: two furnaces, one of 200 tons capacity, operated throughout 1910, a second furnace of 300 tons capacity, operated 329 days in 1910.

Algoma Steel Company, Limited, Sault Ste. Marie, Ont., a constituent Company of the Lake Superior Corporation: two furnaces at Steelton, near Sault Ste. Marie, of 250 tons capacity each, operated throughout the year. This company also has under construction a 400-ton furnace, a 12-inch and 18-inch merchant mill, and a complete installation of by-product coking ovens (110 ovens, Koppers type, with capacity of 1,100 tons of coke per day).

The Atikokan Iron Company, Limited, Port Arthur, Ont.: one furnace of 100 tons capacity, operated for 8 months during 1910.

Ferro-silicon, ferro-chrome, ferro-phosphorus, etc., have been made in electric furnaces at Buckingham, Que., by the Electric Reduction Company, Limited; the furnaces, however, were not in operation during 1910. Ferro-silicon has also been made in electric furnaces at Saulte Ste. Marie, and at Welland, Ont. The electric furnaces operated by the Electric Metals Company were in operation during 1910. These furnaces, constructed some three years ago, consist of four furnaces of from 1,000 to 1,500 horse-power each, the daily production being from 5 to 8 tons.

The imports of ferro-silicon, manganese, etc., during the calendar year 1910, were 18,900 tons values at $464,741, or an average of $24.59 per ton. The imports during the calendar year 1910 were 17,699 tons valued at $411,536, an average of $23.25 per ton.

Returns of steel production received direct from the producers showed a total production of ingots and castings for 1910 of 822,284 tons, as compared with 754,719 tons in 1909, and 588,763 tons in 1908. In 1910 the production of open-hearth ingots was reported as 586,932 tons, Bessemer ingots 222,668 tons; direct open-hearth castings 18,085 tons, and other steels 599 tons; compared with 1909 there was an increase in total production of 67,565 tons, or nearly 9 per cent.

Following is a list of firms making steel in Canada:—

Dominion Iron and Steel Company, Sydney, N.S.
Nova Scotia Steel and Coal Company, New Glasgow, N.S.
Montreal Steel Works, Limited, Montreal, Que.
The Algoma Steel Company, Sault Ste. Marie, Ont.
The Hamilton Steel and Iron Company, Hamilton, Ont.
The Wm. Kennedy Sons, Limited, Owen Sound, Ont.
The Ottawa Steel Castings Company, Limited, Ottawa, Ont.
The Ontario Iron and Steel Company, Limited, Welland, Ont.

The production of finished rolled iron and steel in Canada from 1906 to 1910, as ascertained and published by the American Iron and Steel Association, was as follows, in long tons:—

Annual Production of Rolled Iron and Steel, 1906-10.

Products—Gross tons.	1906.	1907.	1908.	1909.	1910.
Rails	312,877	311,461	268,692	344,830	366,465
Structural shapes and wire rods	48,351	65,541	41,520	74,136	80,993
Plates and sheets	15,202	18,493	11,656	36,241	26,642
Nail plate, merchant bars and all other finished rolled forms	195,312	204,684	174,649	207,534	265,711
Total	571,742	600,179	496,517	622,741	739,811

ELECTRIC STEEL EXPERIMENTS.

A German steel company carried out a few experiments on a 3-ton Girod furnace preparatory to equipping their plant with electric furnaces. That connections to such a furnace can play such an important part in the life of the lining and the power consumption of it is well emphasized in the changes made by the author in question on his furnace. Where one connection was made to the top electrode and another to the bottom electrode it was found that the arc was thrown strongly against the opposite side of the furnace to the conductors. The top conductor was then split into two and led to the electrode on opposite sides, a single conductor being used on the bottom electrode. With this system the arc was blown toward the line. The final solution of the problem was to split both the conductors, bring them up to the furnace many feet underneath and then rise vertically, a pair on each side of the furnace, carrying the conductors leading to the top and bottom electrodes just as far as possible side by side. To increase this length the bottom electrodes were in electrical connection with the shell of the furnace so that connection with them could be made high up on the side of the furnace. The splitting of the conductors keeps the arc central and saves half the lining and all trouble with blowing out of the arc. Even the shell of the furnace was finally made of steel of low permeability. The energy saving in the conductor system and shell as revised amounted to 10 per cent. over the first installation. The flat circular arc now carried on the furnace means an even greater saving of electrode, as previously when it was thrown off to one side it caused very uneven consumption and consequent waste of electrode.

The present system of working is to charge the furnace with about three tons of open-hearth metal and put on a current of 4,000 to 6,000 amperes. A highly oxidizing slag is formed, and all the phosphorus and some of the sulphur is removed during this oxidizing period. The bath is then deoxidized under a new slag formed of lime, sand, ferro-silicon and petroleum coke or scrap electrode ends. This removes sulphur down to 0.01 per cent. On an average five charges are worked in 12 hours, though this is dependent on the amount of impurities to be removed.

With the original form of two conductor connections where the arc was thrown to one side, the silica roof over that side even with air cooling, lasted only 20 heats. With the four-conductor system the roof now lasts 60 to 70 charges. Experiments are not yet completed as to the economy of using other materials in place of silica for the roof.

The side walls were first formed by ramming a mixture of magnesia and tar around a core shaped like the inverted frustrum of a pyramid. Such a lining cost £36. It was later determined that dolomite would most economically replace the magnesia, so all linings are now made of this material. They last 120 charges and cost £17. The total cost of lining, including repairs to slag line between heats, amounts to 1s.

3d. per ton of steel. The area of the ends of steel electrodes in the bottom bears the ratio of 0.05 to 80 to that of the whole bottom.

The bottom electrodes are water-cooled in the ends projecting outside of the furnace. The dolomite bottom is rammed in between them with an air tamper, such a bottom lasting 1,000 heats in a furnace run very intermittently. A calorimetric determination of the heat carried out in the cooling water of these bottom electrodes gave 10.1-kw.-hours for the 130-minute run, or about 1.01 per cent. of the total electrical energy supplied, or 2.9-kw.-hours per ton of steel produced. The cooling water used in the top electrode carried out 36.7-kw.-hours, 3.65 per cent. of total energy supplied, or 10.5-kw.-hours per ton of steel.

The running of this small experimental furnace has thrown much light on the nature of many reactions in the refining of the steel. In the oxidation period carbon is but slowly removed, manganese more rapidly, phosphorus very rapidly, and about 20 to 35 per cent. of the sulphur. The sulphur appears to be removed in three ways: In the oxidation period by the action of the iron oxide in the slags; in the deoxidation period by solution in the high lime slags; and volatized as silicon sulphide. It has also been noted that oxides, slag emulsions, and gases have a much more important bearing on the physical properties of the finished metal than the sulphur and phosphorus present.

NEW YEAR'S HONORS FOR CANADIANS.

The following Canadians were honored by King George on New Year's Day:—

Premier R. L. Borden—Privy Councillor.

Lieutenant-Governor J. M. Gibson—K.C.M.G.

Joseph Pope, undersecretary for external affairs—K.C.M.G.

Thomas Cooper Boville, deputy-minister of finance—C.M.G.

Rudolphe Forget—K.B.

E. B. Osler—K.B.

Charles Slemin, Brantford's chief of police—King's medal.

THE ELECTRICAL DEPARTMENT OF LONDON, ONT.

The financial statement of the electrical department of London, Ont., shows that buildings and land cost $21,000; plant equipment, $44,000; distribution system and municipal street lighting, $193,000, which, with other expenditures on capital account amounted to $350,000. The statement of revenue and expense is the most interesting, as there had been some doubt as to whether there might not be a deficit the first year. The total receipts were $78,892.16, including street lighting and other municipal business. The expense for power and operation was $55,692.07, leaving a gross revenue of $23,200.09. Out of this the sum of $16,807.93 has to be taken, this being the amount estimated by the City Council as necessary to cover interest and sinking fund charges on debentures for distribution system, leaving a net surplus of $6,392.16. Included in the expense account is an item of $7,477.98 for the promotion of business. While some municipalities are allowing five years to pay this, London decided upon four and $6,000 was to have been carried forward to be written off in the future, but on account of the excellent showing made already it was decided to write off the full amount this year. Had this $6,000 been added to the assets, the total surplus would have been $12,392.16.

PERSONALS.

Mr. Thomas Graham, of Nanaimo, B.C., has been appointed to the position of chief inspector of metalliferous ores and coal mines.

Mr. C. B. Smith, of the firm of Smith, Kerry and Chace, is back in Toronto again, after a prolonged absence in the West.

Hon. William Harty, president of the Kingston Locomotive Company, has resigned his position. Mr. Æmilius Jarvis, of Toronto, will succeed him.

Mr. R. H. Murray, who has been with Mr. T. Aird Murray, consulting engineer, of Toronto, is leaving on a two months' trip to Scotland and England.

Mr. Hugh Jackson, treasurer of the Positive Clutch & Pulley Co., has resigned his position ao accept the cashiership of The Canadian Fairbanks-Morse Co., Limited, at Calgary, Alta.

Mr. J. P. Hynes, of Toronto, is named as the successor of Senator Frost to the position vacated on ahe Ottawa Improvement Commission. Mr. Hynes is greatly favored by Ottawa architects and other technical gentlemen, while in Toronto a strong effort is being made to secure his appointment.

Mr. Noble, who was employed by The Canadian Fairbanks-Morse Co., Limited, previous to his entering the organization of the Positive Clutch & Pulley Co., Toronto, last June has accepted a position under Mr. Patton, and now has charge of the transmission department of The Canadian Fairbanks-Morse Co., Limited, at Toronto.

Mr. Adolph Butze and Mr. J. R. Nutter have resigned their positions on the staff of the Grand Trunk Railway. Mr. Butze had an eventful career before joining the Grand Trunk. He served with Sherman through the Civil War. Later he was with the Wabash, Missouri Pacific, and Monon Route roads. He is succeeded by Mr. J. H. Guess, who joined the Grand Trunk last February as assistant to Mr. Butze. Mr. J. R. Nutter, who retires from the position of chief clerk to superintendent of eastern division, entered the G.T.R. service November 1st, 1883, as a porter, and subsequently served as clerk in assistant superintendent's office at Richmond, Que., and timekeeper at Montreal, received the appointment he retires from, October, 1897.

OBITUARY.

The death is reported of Prof. Leigh R. Gregor, who, for almost twenty years, has been connected with the McGill University as professor of languages, on January 1st, 1912.

Prof. Gregor was born in Charlottetown, P.E.I., fifty-two years ago, and was educated in the Prince of Wales' College, Charlottetown. He came to McGill in 1878 and entered the Arts course, graduating as B.A., in 1882. Having made a specialty of languages during his studies, he was appointed instructor of modern languages at the McGill High School shortly after he had graduated. In 1892 he was appointed lecturer in German at McGill, and in 1906 was promoted to the rank of associate professor of Modern Languages. He also had the degree of Ph.D. of Heidelberg conferred upon him.

CANADIAN NATIONAL ASSOCIATION OF BUILDERS' EXCHANGE.

City.	Secretary and Address.
Montreal—	J. H. Lauer, Sec., 263 St, James Street.
Toronto—	P. L. Fraser, Sec., 2 Berti Street.
Quebec—	A. Cote, Sec., 23 Rue St. Jean.

Ottawa—W. Hastings, Sec., 22 Metcalf Street.
London—Geo. S. Gould, Sec., Bank of Nova Scotia, Building.
St. Thomas—E. O. Penwarden, Sec., Dowler Block.
Kingston—E. R. Beckwith, C.E., 292 Earl Street.
Guelph—Mahoney Brothers.
Sault Ste. Marie—MacPhail & Wright Cons. Co., Ltd., P.O. Box 835.
Brantford—A. J. Cromar, Sec., 103½ Dalhousie St., P.O. Box 212.
Windsor—J. L. Young, Sec., 44 Campbell Avenue.
Hamilton—B. F. Richardson, Sec., The Building & Contracting Assoc., 60 Market Street.

Halifax, N.S.—H. Roper, care S. M. Brookfield, Ltd., 58 Grandille Street.
Winnipeg, Man.—J. H. Buxton, Jr., Sec., Portage Avenue and Hargrave Street.
Regina, Sask.—H. R. Abbott, Sec., Builders' Exchange.
Calgary, Alta.—A. Chamberlain, Sec., Board of Trade Bldg.
Edmonton, Alta.—A. O. Wetmore, Sec., McDougall Court.
Medicine Hat, Alta.—J. D. Everard Sec., Builders' Exchange.
Lethbridge, Alta.—E. Power, Sec., Acadia Block.
Vancouver, B.C.—Builders' Exchange, 342 Pender Street.
Victoria, B.C.—Chancery Chambers.

COMING MEETINGS.

THE AMERICAN INSTITUTE OF CONSULTING ENGINEERS.—January 16th, 1912, Annual Meeting, Aldine Club, Fifth Avenue and 23rd Street, New York City, at 8 p.m. Secretary, Eugene W. Stern, 103 Park Ave., New York.

THE CLEVELAND ENGINEERING SOCIETY.—January 23, 1912. Special Meeting, Chamber of Commerce Bldg., Cleveland, O. R. C. Beardsley, Hydraulic Engineer, will present an illustrated paper on "The Design and Construction of Dams," with special reference to recent failures. Secretary, F. W. Ballard.

THE CANADIAN SOCIETY OF CIVIL ENGINEERS.—Jan. 24, 25, 26, 1912, General meeting, 413 Dorchester St. West, Montreal. Prof. C. H. McLeod, Secretary.

CANADIAN FORESTRY ASSOCIATION.—February 7th and 8th, 1912. Forestry Convention Meetings held in the Railway Committee Room, Parliament Buildings, Ottawa. Secretary, Mr. James Lawler, Canadian Bldg., Ottawa.

CANADIAN LUMBERMEN'S ASSOCIATION.—February 6, 7 and 8, 1912. Annual Meeting to be held at the same time and place as the Canadian Forestry Association.

CANADIAN NATIONAL ASSOCIATION OF BUILDERS.—The Sixth Annual Convention will be held in Toronto, February 20, 1912.

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, C. H. Rust; Secretary, Professor C. H. McLeod.

QUEBEC BRANCH—
Chairman, P. E. Parent; Secretary, S. S. Oliver. Meetings held twice a month at Room 40, City Hall.

TORONTO BRANCH—
96 King Street West, Toronto. Chairman, H. E. T. Haultain, Acting Secretary; E. A. James, 57 Adelaide Street East, Toronto. Meets last Thursday of the month at Engineers' Club.

MANITOBA BRANCH—
Secretary E. Brydone Jack. Meets every first and third Fridays of each month, October to April, in University of Manitoba, Winnipeg.

VANCOUVER BRANCH—
Chairman, Geo. H. Webster; Secretary, H. K. Dutcher, 319 Pender Street West, Vancouver. Meets in Engineering Department, University.

OTTAWA BRANCH—
Chairman, S. J. Chapleau, Ottawa; Secretary, H. Victor Brayley, N. T. Ry., Cory Bldg.

MUNICIPAL ASSOCIATIONS.

ONTARIO MUNICIPAL ASSOCIATION.—President, Chas. Hopewell, Mayor, Ottawa; Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

UNION OF ALBERTA MUNICIPALITIES.—President, H. H. Gaetz, Red Deer, Alta.; Secretary-Treasurer, John T. Hall, Medicine Hat, Alta.

THE UNION OF CANADIAN MUNICIPALITIES.—President, W. Sanford Evans, Mayor of Winnipeg; Hon. Secretary-Treasurer, W. D. Lighthall, K.C., Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer, J. W. McCready City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. E. McMahon, Warden, King's Co., Kentville, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secretary, Mr. Heal, Moose Jaw

CANADIAN TECHNICAL SOCIETIES.

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang; Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BUILDERS, CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Charles Kelly, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto. Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto.

CANADIAN ELECTRICAL ASSOCIATION.—President, N. W. Ryerson, Niagara Falls; Secretary, T. S. Young, Canadian Electrical News, Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, Thomas Southworth, Toronto; Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; J. Keillor, Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. Frank D. Adams, McGill University, Montreal; Secretary. H. Mortimer-Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, T. A. Starkey, M.B., D.P.H., Montreal. Secretary, F. C. Douglas, M.D., D.P.H., 51 Park Avenue, Montreal.

CANADIAN RAILWAY CLUB.—President, H. H. Vaughan; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, D. McDonald, Manager, Montreal Street Railway; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto, President, G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July, August.

DOMINION LAND SURVEYORS.—President, Thos. Fawcett, Niagara Falls; Secretary-Treasurer, A. W. Ashton, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, W. B. McPherson; Corresponding Secretary, A. McQueen.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President, Killaly Gamble; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian Members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain, and W. H. Miller, and Messrs. W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary, R. C. Harris, City Hall, Toronto.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C.B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, W. H. Pugsley, Richmond Hill, Ont.; Secretary, J. E. Farewell, Whitby.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, J. Whitson; Secretary, Killaly Gamble, 703 Temple Building, Toronto

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary J. E. Ganier, No. 5. Beaver Hall Square, Montreal.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, F. S. Baker, F.R.I.B.A., Toronto, Ont.; Hon. Secretary, Alcide Chausse, No. 5 Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Alfred T. de Lury, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Dr. A. McGill, Ottawa, President; Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, J. P. McRae; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Wm. Pierce, Calgary; Secretary-Treasurer, John T. Hall, Brandon, Man.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. Rosevear, 115 Phœnix Block, Winnipeg, Man. Second Monday, except June, July and August, at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc. Printed forms for the purpose will be furnished upon application.

TENDERS PENDING.

In Addition to Those in this Issue.

Further information may be had from the issues of The Canadian Engineer referred to.

Place of Work.	Tenders Close.	Issue of.	Page
Medicine Hat, Alta., church	Jan. 20.	Dec. 28.	59

TENDERS.

Arcola, Sask.—Tenders will be received until January 15th, 1912, for the erection of an addition to school building at Arcola, Sask. Plans and specifications may be seen at the office of Storey and Van Egmond, Architects, Regina, Sask., or from Jas. R. Donaldson, Sec.-Treas. Arcola S.D. 37, Arcola.

Dauphin, Man.—Tenders addresed to the town clerk, Canora, Sask., will be received until January 17th, 1912, for the erection and completion of a solid brick town hall building for the town of Canora, Sask. Plans, etc., may be seen at the office of the town clerk, Canora, or at the office of J. H. Bossons, architect, Dauphin, Man.

Ottawa, Ont.—Tenders will be received until January 16th, 1912, for the construction of a breakwater at Rimouski, Que. Plans, etc., may be seen at the offices of the District Engineers at Quebec, Montreal, and on application to the postmaster at Rimouski, Que. R. C. Desrochers, Secretary Dept. of Public Works, Ottawa.

Ottawa, Ont.—Separate tenders addressed to the Minister of Marine and Fisheries, will be received until noon of February 26th, 1912, for the following:—1. The construction of one or two steel single screw bucket dredges, to be delivered at Sorel. 2. The construction of a steel single screw hopper barge, to be delivered at Sorel. 3. The construction of one set of compound steam engines to develop 450 indicated horsepower for dredge No. 37, to be delivered at Sorel. 4. The furnishing of fifty steel rock digging buckets, cast steel links and manganese bucket pins, to be delivered at Sorel. Full information and specifications can be obtained on application to the Purchasing and Contracting Agent, Department of Marine and Fisheries, Ottawa. Alexander Johnston, Deputy Minister of Marine and Fisheries, Ottawa.

Ottawa, Ont.—The time for receiving tenders for the construction of a jetty at the mouth of the Fraser River at Steveston, B.C., has been extended to Friday, January 19, 1912. R. C. Desrochers, Secretary Department of Public Works, Ottawa.

Ottawa, Ont.—Tenders will be received until January 24th, 1912, for an Armory at Fernie, B.C. Plans, specifications, and form of contract can be seen and forms of tender obtained on application to the Caretaker of Dominion Public Buildings, Fernie, B.C.; at the office of Mr. Wm. Henderson, resident architect, Victoria, B.C., and at the office of R. C. Desrochers, Secretary Department of Public Works, Ottawa.

Toronto, Ont.—Tenders will be received until January 16th, 1912, by the Board of Control, for the construction of sewers on Hocken Avenue and Ellsworth Avenue, from Vaughan Road to Bracondale Avenue. G. R. Geary, Mayor, Chairman Board of Control, City Hall, Toronto.

Toronto, Ont.—Tenders will be received by the Board of Control until January 16th, 1912, for the supply of lead for 1912. Specifications at the office of the City Engineer. G. R. Geary, Chairman Board of Control, City Hall, Toronto.

Victoria, B.C.—Tenders for the erection of a six-story reinforced concrete building, for Messrs. C. Hayward and F. Barnard, will be received until January 15th, 1912. Bresemann & Durfee, Architects, Sayward Bldg., Victoria.

CONTRACTS AWARDED.

Fort William, Ont.—Tenders for the structural steel work for the four main buildings of the contemplated tube mills have been called for, and will be opened January 15th. All the other work in connection with the structures will be let to local contractors.

Lethbridge, Alta.—The bids for the sewage disposal works are given as follows:—

Tender	Firm	Price
No. 2.	J. A. Broley, Fernie, B.C.	$65,439.78
" 3.	Smith Bros. & Wilson, city	63,720.00
" 4.	Hotson, Leader & Goode, Lethbridge, Alta.	63,522.24
" 5.	W. Manders, Edmonton, Alta.	79,527.29
" 7.	Allison & Co., Toronto	65,987.48

The successful tender for the sewage disposal plant was that of Messrs. Hotson, Leader & Goode, of Lethbridge, at a price of $63,522.24. The consulting engineer for this work is Mr. T. Aird Murray, of Toronto. City engineer, Mr. A. C. D. Blanchard.

Lethbridge, Alta.—Following is the analysis of bids for street paving:—

Tender No.	Prices			Remarks
	$	$	$	
1. Dom. Pavers, Ltd.	3.97	3.99	3.94	4-in. wood block
Dom. Pavers, Ltd.	3.74	3.76	3.71	3½-in. wood block
Dom. Pavers, Ltd.	3.49	3.51	3.46	3-in. wood block
2. "National"	3.20	3.26	3.25	sheet asphalt
3. "Crown"	2.69	....	....	sheet asphalt
4. "Eloso"	2.65	2.69	2.59	sheet asphalt
"Eloso"	2.50	2.54	2.43	asphaltic concrete
5. "Kettle River"	4.45	4.47	4.43	3½-in. wood block
6. "Warner Quinlan"	3.05	....	....	sheet asphalt
7. "Bitulithic"	2.90	2.93	2.97	bitulithic
8. Gorman, Clancy & Grindley	....	....	2.49	Dolarway

The street paving is divided into two contracts, 17,000 square yards going to the "Bitulithic & Contracting Company," Winnipeg, at $2.93 per square yard; and 11,000 sq. yds. going to the "Eloso Company," Vancouver, at $2.43 per sq. yd. City engineer, Mr. A. C. D. Blanchard.

London, Ont.—Hon. F. D. Monk. Minister of Public Works for Canada, has awarded the contract for the new breakwater at Port Stanley to Mr. M. J. Hogan, of Port Colborne. The cost is estimated at about $275,000.

Ottawa, Ont.—The contract for the construction of the smallpox hospital on Porter's Island, has been awarded to Mr. George A. Crain.

Ottawa, Ont.—Messrs. Jones & Girourard are the successful tenderers for a bridge for the city of Ottawa, their price being $99,500.

Ottawa, Ont.—The Norton-Griffiths Company have received the contract for the work of the St. John Harbor Improvements, Courtenay Bay, this company having contracted to do the work for $7,700,000.

St. John, N.B.—Messrs. M. Connolly & E. P. Charleson have the contract for the construction of wharves at Sand Point, West St. John, at a cost of $800,000.

Sydney, N.S.—The Saunderson Manufacturing Company have secured the contract for the supplying of the necessary roofing velvet for the Dominion Iron & Steel Company's new nail mill, which is now being constructed.

Victoria, B.C.—The tender of Mr. Thomas Stedham for the erection of a reinforced concrete lighthouse, forty feet in height, together with dwelling, boathouse and oil-shed at Sherringham Point, near Sooke, has been accepted by the Marine and Fisheries Department.

Vancouver, B.C.—In connection with the Seymour Creek Extensions the following contracts have been awarded: Steel pipe, Messrs. Balfour, Guthrie & Co., for $75,900. valves, Messrs. A. J. Forsyth & Co., for $8,687; both are Vancouver firms. The contract for trenching has not yet been awarded.

Vancouver, B.C.—The Union Steamship Company have closed the contract for the extension to its dock, the successful tenderers being Messrs. O'Brien, McCaughey & Lamcke. The contract for the shore end of the improvements has been let to Messrs, Ironsides, Rannie & Campbell, and the contract for the new office building which will be erected there has been awarded to Mr. J. McNee.

RAILWAYS—STEAM AND ELECTRIC.

Eastern Canada.—A movement is under way to have the Dominion Government place the York and Carleton Railway under the management of the I.C.R.

Montreal.—A batch of charter amendments were put through the city council recently. They will form part of the Montreal bill to be submitted to the legislature at the present session. Among the powers the city is asking is the right to establish and operate or lease one or more underground tramway lines, to be operated by electricity or other motive power, and the right to regulate the operation of auto-bus lines.

Montreal, P.Q.—The Montreal & Northern Colonization Railway Company has applied to the Legislature for power to tunnel Mount Royal. The company is also seeking extension of the time limit for buliding its line from Montreal to the National Transcontinental.

Montreal, P.Q.—The municipal council are preparing a bill to be submitted to the legislature at the present session, asking the right to establish and operate or lease one or more underground tramway lines, to be operated by electricity or other motive power, and the right to regulate the operation of auto bus lines.

Montreal, P.Q.—The plans of the Canadian Northern Railway for improved passenger and freight facilities on the island of Montreal, were officially laid before the Board of Control on January 9th. These plans provide for a tunnel through Mount Royal, an elevated railway and a freight line.

Northern Ontario.—It is reported that further exploration of the James Bay slope of Ontario, as well as the Moose River estaury and the James Bay shore, will be undertaken next spring under the direction of the Temiskaming & Northern Ontario Commission.

Port Arthur, Ont.—The Canadian Northern Railway propose erecting a new steel dock. This dock will be about 800 feet long, and will be arranged so that several boats can unload at the same ime.

Ottawa, Ont.—A law suit involving rather a unique technicality is being heard in the courts. The Peerless Brick Company and the Canadian Northern Railway are the principals. The Canadian Northern Railway desire to expropriate the pits of the brick company, basing their compensation on the point that the property is mud. The brick company contends that the area is a "mine" of clay. It quotes the Railway Act, which states that a railway has not the power to expropriate lands which might obstruct the workings of a mine. The compensation asked for is $40,000, which the railway considers too large. The action has been adjourned until April 10, 1912.

Ottawa, Ont.—The management of the Ottawa, Montreal and Eastern Railway Company will apply at this session of parliament for extension of time to complete the work now under construction.

Toronto, Ont.—An application will be made by the Toronto Suburban Railway Company to the Legislature of the Province of Ontario at its next session for an Act authorizing the company: To extend its line from some point at or near Guelph, in the County of Wellington, to some point at or near Berlin, Preston, Hespeler, and Galt, in the County of Waterloo, and thence to a point at or near Hamilton, in the County of Wentworth, passing through or near the Townships of Guelph, Waterloo, Dumfries, Puslinch, Beverley, Flamboro West and Ancaster.

Toronto, Ont.—The civic percentage of the Toronto Railway Company's earnings for 1911 amounted to $687,650.44. In addition there was also $83,000 in mileage rates, and taxes of $50,000, or a total of over $820,000. The percentages show an increase of $91,353.09.

Toronto, Ont.—A proposal is under way for the construction of a railway to serve a portion of the fast growing suburban district around Toronto. The purpose of the three-mile railway, which will have Lambton and Sunnyside as its terminals, is to provide an efficient service for the property owned by the Toronto Land Corporation, the concern backed largely by English capital, which has promoted the Humber boulevard scheme. The route at present is purely tentative. As planned it runs down the west bank of the Humber from Lambton to Bloor Street, where it crosses and follows Jane Street to the Lake Shore Road. It might follow the Lake Shore Road, or might cut across the old Belt Line Railway about the brickyards, and cut Windermere Avenue and Ellis Avenue, crossing the Grenadier Pond on piles.

Toronto, Ont.—The plans of the new Union Station will be up for discussion and examination when the Dominion Railway Board sits in Toronto on February 8th. These plans will be completed and filed with the City Solicitor by February 1st, the idea being that a week at least should intervene to allow examination of them before the board's meeting. In this connection it will probably be necessary to bring up the whole question of the viaduct and the York Street bridge once more. The whole general question of the entrance of the Canadian Northern Ontario Railway to Toronto at the north end of the city, will also be up for discussion.

Western Canada.—A number of towns and cities in Western Canada are preparing to petition the government in an endeavor to secure the terminus of the Hudson Bay Railway.

Winnipeg, Man.—The appropriations which are now being prepared in Winnipeg for the work of the Canadian Pacific for 1912, will contain an item for the installation of over 1,000 miles of telephone circuits. It will not be long till the telephone system will be used throughout the main line and all branches as well for train despatching.

The authorized mileage of the Grand Trunk Pacific main line and branches is 11,500 miles, of which 1,745 miles are between Winnipeg and Prince Rupert. 1,800 miles are under contract by Transcontintnetal Railway Commission between Winnipeg and Moncton. The company claim that at the completion of railway the trip around the world will be shortened by about a week.

LIGHT, HEAT AND POWER.

Brantford, Ont.—Engineer Sothman, of the Hydro-Electric Commission, addressed the Brantford council, pointing out that Blue Lake and St. George, just west of Brantford, were desiring hydro-electric power, and if Brantford came in matters would be greatly facilitated. If not, these places would have to be supplied either from Dundas or Galt. It is considered likely that the by-law will be submitted to Brantford ratepayers at an early date.

Calgary, Alta.—An estimated total of $200,000 for electric light extensions for 1912 and $168,000 for extensions to the city power plant during the coming year have been ap-

Tarvia

Preserves Roads
Prevents Dust—

Charles Street, Stratford, Ontario, showing "Tarvia Modern Pavement."

Stratford's Experience with Tarvia

STRATFORD, Ontario, did some thorough and successful work with Tarvia X in 1910 and the accompanying photograph shows a section of Charles Street in that city built by the Tarvia Modern Pavement Method.

Tarvia X was used as a binder throughout the road on a Telford base. Although the job was done by the somewhat primitive barrel-and-kettle method, the total cost was only $1.32 per yard.

The Tarvia, filling the voids of the stone, acts as a plastic matrix, keeping the stone in position, preventing all internal movement, resisting water and frost, protecting the road against automobile traffic and preventing the formation of dust.

After its first year of use, the street is in excellent condition and is giving perfect satisfaction. It has been visited by various engineers, all of whom agree as to the success of the work.

This is only one of thousands of instances of successful Tarvia construction.

We will be glad to send to any inquirer a booklet showing many other cases.

The Paterson Manufacturing Co., Limited
Montreal Toronto Winnipeg Vancouver

The Carritte-Paterson Manufacturing Co., Limited
St. John, N.B. Halifax, N.S.

proved by the council. The particulars of the estimates in each case are as follows:—

400 additional street lamps, wire and labor	$40,000
Transformers for light and power	20,000
Meters	18,000
Cross arms	2,000
Poles	10,000
Hardware	5,000
Labor on overhead construction	40,000
New sub-station on Ninth Ave. West, and equipment	20,000
Underground lead covered cable (feeders) and labor	30,000
Sundry accounts	15,000
Total	$200,000

1 Exciter for 1,000 K.W. ry. motor generator	$ 1,000
4 Water tube boilers 350 H.P. each	32,000
Bricking in boilers	2,000
4 Mechanical chain grate stokers	8,000
1 2,500 K.W. steam turbo generator, complete	65,000
1 1,000 K.W. ry. motor generator, complete	25,000
1 Exciter set for 300 K.W. motor generator	800
1 Feed water heater, closed type	2,000
2 Feed pumps	4,000
Boiler and feed piping	2,500
Auxiliary piping	2,000
Foundations for turbine motor generator, feed pumps, feed water heater, etc.	2,500
1 5,000,000 gallon motor-driven pump	5,000
Extension to power house sewer	2,000
Sundry extensions	15,000
Total	$168,000

Montreal, P.Q.—Owing to the severe cold weather, considerable trouble was experienced by the Montreal Light, Heat & Power Company in their gas mains. The trouble existed in all parts of the city at once. The absence of the usual snow blanket gave the sudden severe frost easy access to the ground, and it penetrated to the level of the gas mains.

Ottawa, Ont.—One of the first measures to be brought before the new city council will be a resolution urging the Hydro-Electric Commission to expropriate for the City of Ottawa the water power on the Ontario side of the Chats Falls, owned by Hon. William Harty, of Kingston. The engineers sent down by the Hydro-Electric to investigate the Ottawa power situation have reported that the Chats Falls is by all odds the one best suited for the City of Ottawa.

Quebec, P.Q.—The contract by which the Dorchester Electric Company agrees to proivde the city's lighting for ten years is based on rate of seven cents per kilowatt hour, as against the present rate of 12 cents (or 15 cents if not paid within a certain time) charged by the Q.R.L and P. Company.

Regina, Sask.—The long delayed generator has at last been shipped by the constructors in England. It will likely be at least another month before the generator is installed by the local power house officials, and in the meantime the units at present doing service will have to continue carrying an overload. The generator was to have arrived in the city some months ago, but shipment was delayed. A shipment was made during November, and the power house officials were assured at that time that everything would be on hand during December. The shipment arrived, but consisted of the turbine only, the electrical equipment having been left out. The electrical equipment was shipped from Liverpool on December 22, according to communication. It is not expected that the shipment will reach Regina for several weeks, and another week willl likely be occupied in setting up the unit.

Saskatoon, Sask.—Some difficulty is being experienced in placing the machinery in the new power house as a result of defects of the travelling crane, and an employee of the manufacturers is investigating. It appears that the track on which the crane travels is all right, and the traveller itself could not be better, but the lifting power of the blocks is said to be less than the guarantee. The warranty from the manufacturer was to the effect that the crane would lift and carry a weight of fifteen or sixteen tons, but the crane has failed on lifting a weight to the extent of only six tons. It is thought that the blocks are not of the correct capacity, and, in view of this, an imperative wire was dispatched to the firm to send an expert forthwith to adjust it. This was necessary, as some of the parts of units to be installed weigh nearer twenty tons than sixteen, and the assistance of the crane is badly needed, its defection being severely felt in hampering the installation of machinery. Under the circumstances, it is doubtful if any accurate prediction can be made as to when the new plant will start in full operation, and in the meantime the overloaded old plant is being worked to its utmost capactiy. Preparations are being made for converting this plant into a pumping station directly the new system of power production is supplying the electrical energy which the city so badly requires.

Saskatoon, Sask.—The same generator which caused so much trouble at the city power plant a few weeks ago was again the cause of considerable inconveninece to the city. The trouble was due to the heavy load burning out three or four coils and these had to be replaced before the generator could be put in commission again. The burning out of the coils did not put the entire plant out of commission. One generator was still in working order aud thus sufficed to supply a feeble current to the city.

Toronto, Ont.—The Ontario and Minnesota Power Company, of Vernon, has applied for an injunction against the Rat Portage, the Rainy River and the Shevlin-Clarke Lumber Companies, the Northern Construction Company, and Lockhart & Company, to restrain the defendants from damming up the waters at the head of Rainy River. The power company has a large plant at Fort Frances. It claims that the defendants dams are constructed all the way up the river, some being 200 miles away, and that the flow of water is seriously weakened.

Among the questions taken up before the International Deep Waterways Commission which met in Washington, January 10th, was the proposition to render deep water navigation possible from the mouth of the Richelieu River at Sorel, up that river, through Lake Champlain and Lake George to Albany and thence to New York, and the Long Sault dam project.

SEWAGE AND WATER.

Berlin, Ont.—H. J. Bowman, of Berlin, has been engaged to prepare plans and specifications for the proposed extension to the waterworks.

Montreal, P.Q.—The Aldermanic caucus have decided to approve in council the recommendation of the Board of Control that the tax for water used for baths in dwelling houses should be abolished.

Port Arthur, Ont.—The city engineer has recently reported to the council upon a new and extensive water supply project for the city. The proposal includes the provision of new duplicate intake pipes at a location about two miles east of the present intake pipe, which was recently badly damaged by alleged dredging operations. Also the extension of a considerable length of force main and new pump station. The estimated cost is about $200,000. We understand that the whole project has been submitted to Mr. T. Aird Murray, of Toronto, as consulting engineer, and that that the new city council will do nothing in the matter until the report is received.

Toronto, Ont.—Mr. Isham Randolph, of Chicago, one of the members of the Board of Water Experts, sent to the Board of Control his account for services and expenses from March 20th to December 29th. The amount is $4,678, and includes railway and hotel expenses and his fee of $100 per day. He had been paid $1,500 on account, leaving a balance due of $3,178. The Mayor said the experts now only had to report on the cost of the larger scheme for a new intake and reservoir at Scarboro. Controller Hocken agreed with the Mayor that the sewage effluent would have to be chlorinated. Then, he thought, it would be safe to have another intake at Scarboro Heights, and he favored that plan. Ultimately there should be a third intake in the west. Three smaller units would be better than concentrating on one.

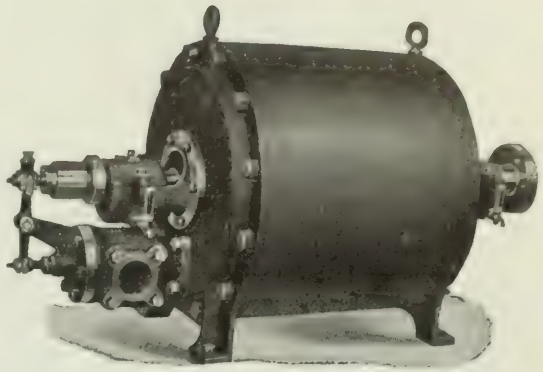
Vancouver, B.C.—The $100,000 Little Mountain Reservoir in South Vancouver, which was built under the direction of Consulting Engineer Burwell for the City of Vancouver, has been completed, and now contains several feet of water. The following are the dimensions of the reservoir and its capacity: Top length of reservoir, 612 feet; bottom length of reservoir, 514 feet; top width of reservoir, 377 feet; bottom width of reservoir, 280 feet; depth from top to bottom, 25 feet; slopes of inside, two horizontal to one vertical; top width of bank, 45 feet; width of base of bank, 145 feet;

Kerr Turbo-Generators

FOR SMALL LIGHTING PLANTS

The Kerr Turbine is peculiarly suited to generator driving and our sets are made in suitable sizes to fill all requirements up to 500 kw. alternating and 350 kw. direct current. The operation is economical throughout a wide range of initial steam pressures, the steam economy is improved by superheat, and any exhaust conditions are permissible. When operating non-condensing, the steam consumption compares favorably with that of a high speed engine of the same capacity, while in condensing plants the economy at full loads equals that of the best compound engine and at fractional loads is much better.

A Kerr Turbo-Generator for lighting or small power or both is extremely profitable in any plant having power boilers, since the freedom of the turbine exhaust from oil makes reuse of the exhaust inexpensive and safe for boiler feeding or any other purpose where clean low pressure steam is desirable. See Bulletin No. 22.



KERR STEAM TURBINE

LIMITED

Factory: 1551 Granville Street, VANCOUVER, B.C.

P.O. Box 563. Full Particulars and Estimates Furnished.

total excavation, 80,000 cubic yards; rock excavation, 18,000 cubic yards; plain concrete lining, 15,030 square yards; reinforced concrete lining, 9,835 cubic yards; cost of excavation, $52,000; cost of concrete lining, $43,000; capacity when filled to the top, 29,000,000 imperial gallons; with a depth of 22 feet, 25,000,000 imperial gallons; elevation of top above sea level, 400 feet; total cost, $95,000, being $3.80 per 1,000 imperial gallons. The one 24-inch pipe into the reservoir acts both as inlet and outlet and is provided with a balanced valve inside of the reservoir, consisting of a vertical 24-inch pipe suspended within a steel tower, by which arrangement the outflow from the reservoir can be shut off when desired, and any additional connections or repairs made to the supply pipe without emptying the reservoir.

BUILDING.

Brandon, Man.—A new factory is to be erected by the Brandon Construction Company at the corner of Princess and 16th Street. The new factory is for manufacturing sash, doors, and other fittings for construction.

Montreal, P.Q.—Preparations for building a large concrete factory in the Park Avenue extension section are under way. It is understood that the factory will employ 400 persons. The property is situated on Beaumont Street, at the foot of King Edward Boulevard, and comprises an area of about 200,000 square feet.

Port Colborne, Ont.—About $50,000 was spent in Port Colborne during the year 1911 on building operations outside of the new Maple Leaf Mill. The buildings include a new bank building of terra cotta brick and a new theatre. The prospects for 1912 are the best in the town's history. The cement company is spending about half a million dollars, doubling its capacity. The cork works expects to double its capacity. The Union Smelting Works of Buffalo will erect a $200,000 plant, and it is expected the C.P.R. will run a branch line into the town.

CURRENT NEWS.

Carleton Place, Ont.—The by-law to borrow $150,000 to install a system of waterworks and sewerage in Carleton Place was carried by a majority of 216.

Castor, Alta.—A water tank near this point collapsed and crushed out the life of one young man.

Desbarats, Ont.—Owing to lack of a bridge, communication has been cut off between St. Joseph Island and the mainland. A large number of people are at Desbarats awaiting to get across, while many on the island from Sault Ste. Marie and other points are unable to return. Applications have already been made to both the Provincial and Dominion Governments for relief, by having the proposed bridge built.

Esquimalt, B.C.—According to a report of the American Consul at Victoria, B.C., the British Columbian Marine Railway have completed financial arrangements for the construction of a large graving dock at Esquimalt, which is to be 1,000 ft. long and will be constructed on similar lines to the one at Southampton. It is proposed to build the dock of reinforced concrete with granite facings and to employ electric plant for pumping purposes, etc. Work is to be started at once in order that the dock may be completed before 1915, or in time for the opening of the Panama Canal.

Fort William, Ont.—It is reported that the Good Roads by-law carried in all the townships in this vicinity except Oliver, and it is expected that the by-law will be legalized there.

Hamilton, Ont.—The Hamilton Bridge Works Company has been granted a building permit for the erection of five concrete, steel and corrugated iron buildings in East Hamilton for the Steel Company of Canada. The cost is given as $100,000, and the different buildings are: Rod mill, 83 by 550; bloom and billet mill, 65 by 400; open crane runway building, 50 by 400; boiler house and gas producing building.

Hamilton, Ont.—It is stated that $2,500,000 is the amount involved in the deal by which a large American gas and coke concern will shortly take over the Hamilton Gas, Light Company, and the Ontario Pipe Line Company, giving it control of the natural and artificial gas situation here. The Manufacturers' Gas Company will likely be taken in later, too. The new company will erect a mammoth new plant here and carry on an immense coke business.

London, Ont.—The comparative building statistics for 1910 and 1911 for London, Ont., are as follows:—

	No.	Value
1911 December	38	$ 187,553
1910 "	17	63,085
1911	1039	1,036,880
1910	882	805,074

Montreal, P.Q.—Estimates prepared from authentic information on building figures for 1911 show a total of $25,820,144 for Greater Montreal. While these figures are nearly two million dollars lower than those for last year, they are regarded as extremely satisfactory, since last year's figures were swollen by the taking out of permits by the C.P.R. for work amounting to several millions of dollars, while the present year has not been marked by any such immense expenditure.

Ottawa, Ont.—It was announced on January 9th that the good roads programme which the Federal Government proposes to inaugurate, will be attended to by Hon. Frank Cochrane, Minister of Railways. Mr. F. W. Campbell, the present Deputy Minister, will probably be the head of the new department.

Ottawa, Ont.—The main estimates of the Federal Government will contain an appropriation of approximately one million dollars for the further improvement of the St. Lawrence route. Much additional dredging will be done, particularly in the vicinity of Cap a la Roche.

Owen Sound, Ont.—The municipality are considering an offer recently made by the Standard Chemical, Iron and Lumber Company, regarding the installation of a blast furnace. The president, Major Peuchen, in an address to the ratepayers remarked that the company had decided to establish a smelter on the Georgian Bay, and they had almost closed the deal with Midland, which had offered a dock, a site, loan and bonus. If the ratepayers should decide to carry the project, the terms laid down by the company are: The town to furnish a dock to cost at least $30,000, and the speaker stated that if it cost over $35,000 the company would pay the extra cost. A bonus of $25,000 and a loan of $25,000 is also to be given the company, but the bonus is not to be handed over until the plant is erected and running. On the $25,000 loan the company will pay back $1,250 per year, and they will lease the dock at $100 per year. The dock will be 600 feet long. The town is also to furnish the company with a free site. The town council at an early meeting will take up the by-law for the raising of the necessary money, and if it receives its first and second readings, it will be submitted to the ratepayers to be voted on.

Province of New Brunswick.—The year 1911 in this eastern province was the dryest in seventeen years. The total precipitation of rain and melted snow was 26.25 inches, while the average for the past seventeen years was 34.68 inches.

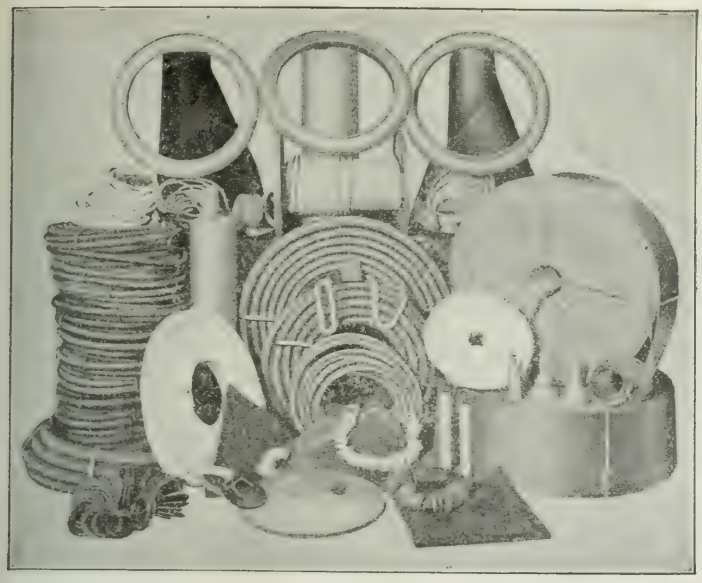
Quebec, P.Q.—The municipal council is in receipt of a cheque for $300,000. This amount is a refund of a subscription raised to assist in the construction of the ill-fated Quebec Bridge. This refund was provided for in the Act of Parliament, passed at the instance of the Laurier Government, providing for the dissolution of the old Quebec Bridge Company and the assumption of its obligations by the Government of Canada, after the collapse of the first bridge.

Regina, Sask.—Provision has been made in the civic estimates of expenditures for the installation of a gas plant during the year, at a cost of $200,000. At the time the Street Railway service was inaugurated it was announced that the next civic undertaking would be a municipal gas plant, and provision is made for a start on the work during the early part of 1912. Although the plant is to cost $200,000, only $20,000 is provided for the start on construction, investigations as to the best plant, probable revenue, advisability and necessity for plant.

Toronto, Ont.—In the past five years the total increase of assessable property in this city amounts to $159,571,000, and at the present time the total taxable amount of assessable property is $806,751,673. These figures show an increase of $32,239,000 over last year.

Vancouver, B.C.—Mr. A. D. Swan, who has been employed by the Dominion Government to plan Greater Vancouver's harbor improvements, and Mr. R. S. Lea, who is laying out a scheme of sewerage for Greater Vancouver, arrived from Eastern Canada, and at once began the preliminary

Use Goodyear Non-Chip, Rot-Proof Hose



A Few of the Lines We Manufacture

Don't tie up money in hose that begins to need repairs after a *few weeks'* use.

Buy the only dependable, never-mend hose—

GOODYEAR Water Hose

Built by World's Greatest Hose Experts for Pulp and Paper Mills, Manufacturers, Boiler Rooms, Flushing and Garden Use and All Uses Where Cold Water is Carried

The strongest, longest lasting hose made.

Goodyear Hose is built on principles that years of experience have proved most practical. The fabric is cut on right bias to give greatest strength and endurance and to resist expansion and elongation—one of the prevailing faults of common hose.

Only highest grade material used. Rot-proof because specially treated and covered with heavy, durable canvas that can't chip off and expose tube to weather.

Can be furnished with round, half-round or flat wire winding or Marlin wind.

Steam Hose—Air Hose—Suction Hose

We manufacture highest grade hose for every purpose. Used throughout the Dominion. Wherever used, is *saving money.*

All Goodyear products built according to same methods employed by Goodyear Tire & Rubber Co., Akron, Ohio—one of the best known and most successful rubber goods manufacturers in the United States.

Tell us your requirements. Let us send catalog. Write today. 2

ary work of getting in touch with local conditions. It is understood that Mr. Lea is now prepared to place the whole sewerage scheme before the joint committee, defining the position of the mains that will have to be constructed at once and also outlining the work necessary during the next ten or fifteen years.

Welland, Ont.—The building figures for Welland, Ont., for 1911 is as follows: Public and business, $213,878; residences, $128,930. If the factories and residences erected in the suburb (Welland South) were added, the total would exceed $1,000,000. During last year an unsuccessful effort was made to extend Welland boundary to take in Welland South.

York County, Ont.—Mr. E. A. James, engineer for the York County good roads, has located an important stone showing about twenty miles from Toronto. This rock can be placed f.o.b. any siding in York county at less than $1.90 a ton, and since this is an exceedingly hard and tough rock and can be delivered at a price almost equal to that of granite, the engineer predicts that it will be the rock largely used in macadam highway construction in this section of Ontario from this time forward.

The Asphalt & Supply Co., Ltd., 213 St. Nicholas Bldg., Montreal, Que., would like to get in touch with some of the larger construction companies on the Pacific coast and middle west, who make a specialty of street and sidewalk paving work. Any firms who are interested are invited to correspond with the company at the above address.

LIST OF PRIVATE BILLS OF ONTARIO LEGISLATURE.

An application has just been received from the Kawartha Transportation Co., who want to build an electric car line in Peterboro, and from there to several of the summer resorts on the Kawartha Lakes.

The Bruce Mines and Algoma Railway Co. want to extend their line from Rydall Bank Station to Algoma, north and east to Hanna and other points on James Bay. The railway company also wants to increase its bonding power to $30,000 a mile.

The town of Brampton wants to introduce a by-law to permit the issuing of bonds amounting to $23,000, to assist the Peace Foundry Co. in obtaining a site for a new plant there.

The town of Haileybury wants power to issue $26,000 worth of debentures for various municipal improvements, including a firehall, municipal building and waterworks extensions.

The town of Milton wants an agreement to guarantee the issuing of bonds to the Williams Shoe Co., who are planning to locate a shoe factory in that town.

The town of Renfrew is making application to validate two by-laws, one for $60,000 for an electric power plant and steam auxiliary. The municipality also wants to install its own lighting plant.

The Dunnville, Wellandport and Beamsville Electric Railway have made application to have a four years' extension made to the time in which the railway is to be completed.

NOVA SCOTIA MINERALS.

The mineral production of Nova Scotia for the year 1911 shows a large increase over the production of the year 1910, and is the largest in the history of the mining industry of the province. The different branches of the industry, with but three exceptions, show large increased outputs, whereas the decreases shown are very small. With the exception of iron ore, pig iron, steel, prices have been the same as during the preceding year.

A total of 6,400,000 tons of coal were mined, this being an increase of 700,000 tons over the production of 1910. The Dominion Coal Company took over and reopened the mines of the Cumberland Railway and Coal Company at Springhill, and have during the year opened three new mines in Cape Breton County. This company have at the close of the year fifteen producing mines and five mines in stage of development on the Island of Cape Breton. At Stellarton the Acadia Coal Company have been engaged in extensive alterations and additions to their equipment, electrifying their plant. At North Sydney the MacKay Mining Company have completed and are now operating a Coal Briquette Plant.

The production of coke for the year was 500,000 tons, an increase of 55,000 tons over the 1910 production. The prinicpal producers and users of coke in the province are the Dominion Iron and Steel Company, and the Nova Scotia Steel and Coal Company.

A total of 840,000 tons of iron ore were imported into the province: 140,000 tons more than the amount imported during 1910, and 40,000 tons of ore were mined in the province, this being 10,000 tons less than the amount mined during 1910.

400,000 tons of pig-iron and 445,000 tons of steel ingots were made, being increases of 50,000 tons and 33,000 tons respectively. The iron-ore, pig-iron and steel markets throughout the world have been dull, and prices consequently low.

At Torbrook the Canada Iron Corporation have completed an ore concentrating plant. This company, in August, on account of the unsatisfactory condition of the iron market ceased to operate their mines. Operations are to be resumed just so soon as the market conditions improve.

At Scheelite, Moose River, the Scheelite Mines, Ltd., continued the development commenced last year in connection with their Tungsten areas. Additional shafts have been put down and long levels driven, good ore has been encountered, a modern concentrating mill and power house have been constructed, the equipments placed and the plant is now in operation. Ore shipments will be made early in the New Year.

At New Ross, the Nova Scotia Manganese Company have lately completed a concentrating mill and power house, and have part of their machinery in place; recent development work at their mine has opened up large bodies of high grade pyrolusite. This company is now prepared to make shipments of ore.

At Lake Ainslie, Cape Breton, the Byrites, Limited, have recently completed a modern mill, and expect to commence shipment of their products early in 1912. The milling of byrites at the mine is a new departure for the province; in the past all ore being shipped from the mines in a crude state.

The following table shows the approximate values of the mineral production of the province for the year:—

Value of Nova Scotia Mineral Products—Year 1911.	
Coal	$19,200,000
Steel	8,900,000
Pig Iron	4,800,000
*Iron Ore	2,475,000
Coke	2,200,000
Quarry products	880,000
Gold	142,000
Clays	190,000
Miss. Scheelite, Manganese, etc.	100,000
Total	$38,887,500

* 120,000 Nova Scotia ore balance imported.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA.

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners. to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from The Canadian Engineer for small fee.

15639—December 19—Relieving C.N.R. from further protection at crossing east of switch at Dauphin, Manitoba.

15640-51—December 20—Authorizing C.N.R. to construct across public road on its Maryfield Extension, Saskatchewan, and two highways on same extension in Saskatchewan.

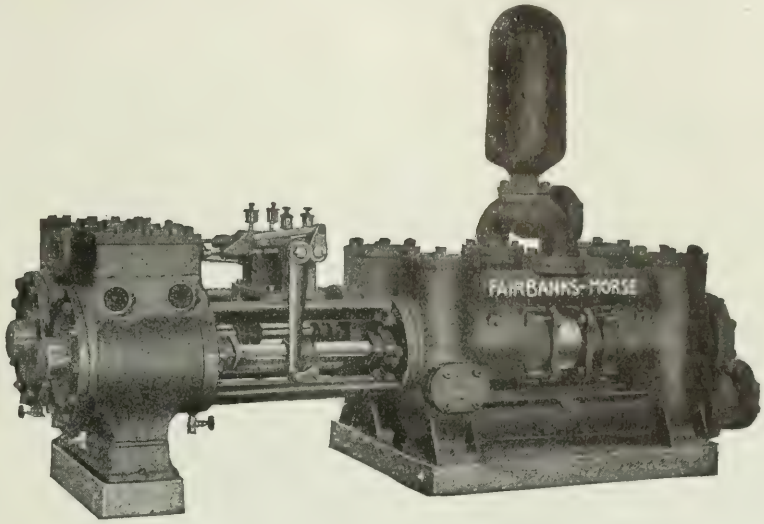
15642—December 20—Authorizing C.N.R. to cross with its Rossburn Line highway and to divert same in Saskatchewan.

15643-44-45—December 20—Approving revised location of C.N.O. Ry. (Montreal-Port Arthur Line), through Twp. of Ross, Ontario, (Renfrew County); and through unsurveyed territory in Dist. of Algoma, mileage 148 to 166 from Sudbury Junction; and revised location through Township of Loughborough, Ct. Frontenac, Ont.

15646-47-48-49—December 20—Authorizing C.P.R. to construct spur for Carbon Oil Company, Ltd., in municipality of Rosser, Manitoba; for city of Moose Jaw, Sask.; for Continental Oil Co., Ltd., Lethbridge, Alberta; for Eley Bros., near Woods, Manitoba.

15650—December 21—Amending Order 15594, of December 12th, 1911, by striking out words "Canadian Pacific Railway Company."

15651-52—December 20—Authorizing T.H. & B. Rv. to operate two spurs in city of Hamilton, into land of Laidlaw Bale Tie Co., Ltd., and also spur into lands of Canadian Drawn Steel Company, Ltd., Hamilton, Ontario.



PUMPS

The superior excellence and splendid results shown by

"FAIRBANKS-MORSE"

pumping machinery are largely due to the fact that for many years we have manufactured Hydraulic Machinery of all descriptions. We are therefore able to build pumps which are properly designed and adapted to every-day use. This is of the greatest importance in a first-class pump, for the usefulness of an engine may be lost if the pumping machine is badly designed.

You will get all these important features when you purchase a "FAIRBANKS-MORSE" pump.

Let us solve your pump problems.

THE CANADIAN FAIRBANKS-MORSE CO. Limited

Fairbanks Standard Scales — Fairbanks-Morse Gas Engines.
Safes and Vaults.

Montreal Toronto Winnipeg Vancouver Calgary St. John, N.B. Saskatoon Ottawa

15653—December 20—Approving plans of G.T.R. for new station at Exeter, Ontario.

15654—December 16—Directing that upon conveyance by the Petrolea Waggon Co., Ltd., of land necessary for interchange track to be constructed by G.T.R. or M.C.R. Cost of work to be divided equally between companies. Application, town of Petrolea, Ont., and manufacturing interests.

15655—December 20—Authorizing city of Fort William to open up Victoria Avenue across C.N.R. at Vickers Street, an additidonal width of 14 feet.

15656—December 20—Directing C.P.R. on or before April, 1912, to submit plans for station at Dysart, Saskatchewan.

15657—December 13—Authorizing B. C. Electric Railway to cross C.P.R. at foot of Twelfth Street, city of New Westminster, B.C.

15658—December 21—Approving location of C.N.R. station to be erected at Veregin, Saskatchewan.

15659—December 19—Directing that effective dates of new freight tariffs required to be filed under Order 12520 of December 10th, 1910, be changed to April 1st, 1912. Tariffs to be filed by C.P.R. and C.N.R. Regina Rates Case.

15660—December 20—Authorizing C.P.R. to construct a spur for T. Kinnear & Co., in city of Peterborough, Ontario.

15661—December 22—Directing that T.H. & B. Ry. maintain light on electric bell at Mohawk Road crossing, mileage 62, from Welland, in city of Brantford, and as soon as same is installed railway company be released from speed limitation at said crossing.

15662—December 21—Relieving C.P.R. from further protection at crossing between Makarooff & Togo, between mile posts 253 and 254, from Winnipeg, Kamsack S.D., 3rd District.

15663-64—December 21—15665—December 22—15666—December 21—Approving location of C.N.O. Ry. station grounds at Lombardy, in Twp, of South Elmsley, at Perth Road, in Township of Loughborough, at Elgin, in Township of South Crosby, at Bedford, in Township of Bedford, Ont.

15667—December—Authorizing G.T.R. to construct spur to premises of St. Mary's Portland Cement Co., Ltd., and Horse Shoe Quarry, in Township of Blanchard, Oxford County, Ontario.

15668—December 21—Extending until January 31, 1912, time for completion of work to be done under Order 14164, dated June 24th, 1911.

15669—December 16—Authorizing G.T.R. to construct bridges at Mill, Peter, Barrett, and Ontario Sts., Port Hope, Ont.

15670—December 16—Re G.T.R. taking lands in Twp. of Etobicoke, Ont., of W. H. Miles, referring taxation of costs under sub-clause (e) of Clause 1 of Order 13418, to J. H. Thom, Taxing Officer of Supreme Court of Judicature for Ontario. Amount taxed and allowed by him to be paid by G.T.R. to applicant.

15671—December 22—Authorizing G.T.R. to construct track on east side of Metcalf St., town of Simcoe, Ontario.

15672—December 22—Amending Order 14606 of August 21st, 1911, paragraph 4, re interswitching at Brandon, Man., $2.00 per car to be revenue of Brandon, Sask. & H.B. Ry. on empties transferred between C.P.R. and C.N.R. at Brandon.

15673—December 22—Approving location of C.N.O. Ry. at Cushing, Que.

15674—December 23—Approving location of South Ontario Pacific Ry. (C.P.R.), proposed station at Waterdown, Ontario.

15675—December 23—Relieving G.T.R. from further protection of 1st crossing west of Port Robinson, Ont.

15676—December 22—Authorizing C.N.O. Ry. to cross and divert public road between Cons. 1 and 2, Twp. of South Elmsley, Ct. Leeds, Ont.

15677—December 23—Approving location of C.N.O. Ry. through Twps. of Chisholm and Ferris, Dist. of Nipissing, Ont., mileage 325.23 to 343.55 from Montreal.

15678—December 16—Varying Order No. 15151, of October 12th, 1911, that gates be put outside of tracks of C.P.R., and new plan to be filed for approval, Royce Ave. Gates, Toronto, Ont.

15679—December 23—Authorizing C.P.R. to cross with its Moose Jaw Northwesterly Branch across highway at mileage 202.77.

15680—December 26—Authorizing C.P.R. to open for carriage of traffic (freight) its railway from Coldwater, mileage 12.2, to Bethany, mileage 88.2.

15681—December 26—Authorizing C.P.R. to reconstruct bridge No. 127.2 on Mountain Subdivision.

15682—December 26—Authorizing C.P.R. to open for carriage of traffic its second track, Moose Jaw S.D., mileage 127.68 to 134.43 from Moose Jaw to Pasqua.

15683—December 23—Recommending to the Governor-in-Council for approval, Rules of G.T.R. Transportation Department.

15684—December 26—Extending until June 30th, 1912, time for completion of spurs into premises of Durham Rubber Co., Bowmanville, Ont., by Toronto Eastern Railway (C.P.R.).

15685—December 23—Directing Central Vermont Railway to ballast its entire line between St. Lambert & Waterloo, Marieville & St. Cesaire, Farnham and Frielsburg and Iberville and Farnham, and repair all bridges, farm crossings, highway crossings ,and fencings, ballast to be 6-inch lift. Work to be completed by October 1st, 1912 and that within 30 days from date of this Order, frogs and guard rails be filled, under penalty of $25 a day.

15686-87—December 27—Authorizing C.P.R. to reconstruct bridge No. 127.2 on Mountain S.D., B.C. Division, and bridge 94.8 on Moose Jaw S.D., over Wascana Creek.

15688—December 27—Authroizing C.P.R. to construct spur for Park Fuel and Lumber Co., at Calgary, Alberta.

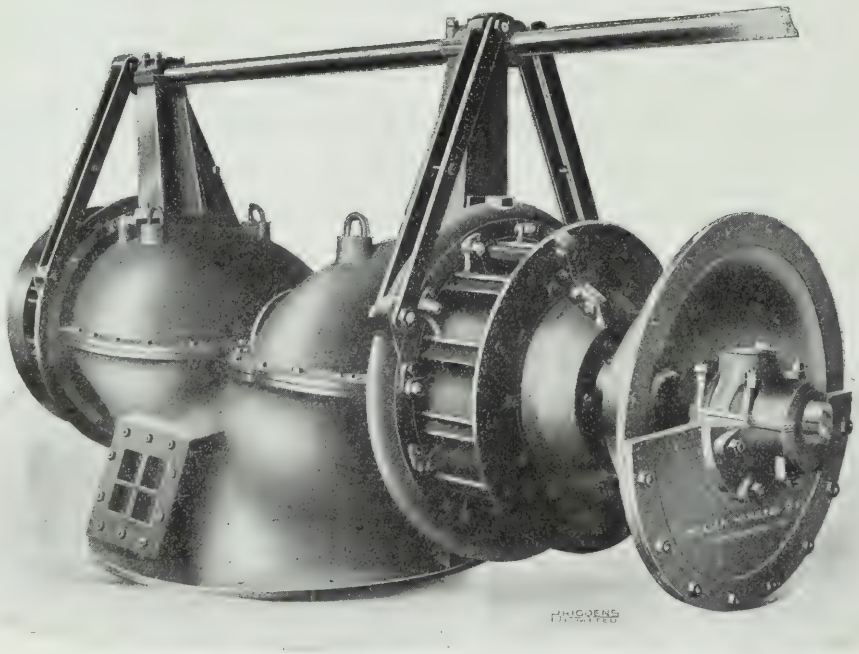
15689-90—December 27—15691—December 23—Approving location of C.N.O. Ry. through unsurveyed territory in Dist. of Algoam, mileage 287 to 307, from Sudbury Junction, and from mileage 307 to 327, from Sudbury Junction, and approving revised location through Twps. of Alice, Fraser, and Richards, in County of Renfrew, Ont., mile 209 to 225.42 from Montreal.

15692—December 27—Directing that C.P.R. install improved type of electric bell at crossing of County Road, 1¼ miles east of Ivanhoe Station, Ontario; 20 per cent. from Railway Grade Crossing Fund.

15693—December 27—Authorizing C.N.R. to construct a spur line to Ritchie Coal Co.'s yards at Edmonton, Alta.

15694—December 27—Authorizing C.P.R. and G.T.P. B.L. Co., to operate their trains over crossing pending installation of interlocker required to be constructed by Order 13663, of May 16, 1911, Melville-Regina Branch, G.T.P. and C.P.R. Bulyea Branch.

15695—December 28—Recommending to the Governor-in-Council lease for sanction between C.P.R. and Dominion Atlantic Ry.



Water Wheel Installations

The Canadian Engineer

An Engineering Weekly

MONTREAL.

Montreal, the commercial metropolis of Canada, situated at the head of navigation, is now entitled to be classed among the great cities of the world. Including the annexations during the past few years, it has a total area of slightly over forty square miles. It extends a distance of about twelve miles in length along the harbor front and its northern extremity floats upon the Riviere des Prairies which, together with the St. Lawrence, makes the Island of Montreal. Of the territory embraced within the borders of the city, a very considerable area would hardly be recognizable as city property. A certain proportion of it is country district; but houses are springing up in every direction and ere many years have passed the entire area will, no doubt, assume the appearance of the suburbs of the city. It may be worthy of remark that until 1910 the area of the city was only in the vicinity of twenty square miles, the additional twenty having been added through annexation of outlying districts since then.

In the matter of population Montreal has increased very rapidly, having almost trebled in twenty years and having considerably more than doubled in ten years, as the following will show:—

Population of Montreal in	1891	[illegible]
do	1901	[illegible]
do	1910	450,000
do	1912	600,000

It must be admitted that a certain proportion of the above increase was due to annexation of outlying districts. Included in the above figures is the population of some districts which, strictly speaking, are really not portions of the city proper but which, in any consideration of the present character, must be included. For instance, West mount's population of 15,000 is included, as is Outremont's 5,000 and some 20,000 in Maisonneuve. This, however, is quite justifiable when it is remembered that Montreal surrounds each of these municipalities and even the citizens of the city, itself, would be unaware that they would be passing through a separate municipality.

In point of population Montreal now stands somewhere among the largest thirty or thirty-five cities of the world. In a recent comparison she stood ahead of Pittsburg, Birmingham, Leipzig, Detroit, Rome, San Francisco, Cincinnati, Mexico, New Orleans, Bristol and other well known large cities and capitals.

Mr. Jas. J. Guerin, Mayor of Montreal.

The increase in population and area, large as it has been, is small when compared with the increase in valuation of taxable property which has taken place. Within five or six years the value of the property has more than doubled, according to the report of the assessors. The value of the property exempt from taxation also has more than doubled. Exemptions for the most part consist of civic property which is owned by educational, charitable or religious organizations. These exemptions in a city which never has sufficient money to carry out works of a character which are representative of good government, have been fruitful of much discussion. An attempt was made a few years ago by which many of the exemptions would be transferred to the taxable list, but little came of it. The following shows the growth in the value of the property under discussion since the beginning of the present century.

	Exempt.	Taxable.	Total.
1900	$ 37,000,000	$148,000,000	$185,000,000
1905	46,000,000	173,000,000	219,000,000
1911	120,000,000	381,000,000	501,000,000

Included in the exemptions are some 38 parks and public squares having an area of slightly over 800 acres and a value of $12,000,000.

During the year 1911, the values of the building permits taken out at the City Hall was approximaely $15,000,000. These figures, of course, represent only new construction in the city proper. Not included in the figures, however, are the newly annexed wards of Longue Pointe and Notre Dame de Grace, these wards having been expressly exempted from the building regulations of the city. It was estimated also that the values registered at the City Hall were 40% under the actual value. In addition to this there is to be added for Westmount $1,335,000; Verdun, $600,000; Outremont $1,500,000; and Maisonneuve, $2,000,000. Altogether, therefore, it is considered that the total building operations for Montreal and vicinity amounted to $26,000,000. This compares with about $28,000,000 the previous year, so that a slight falling off is shown. To explain the falling off, it is only necessary to remember that the permits for some of the largest buildings ever undertaken in the city were taken out in the year 1910.

Some of the principal buildings constructed during the past few years may be shortly referred to as follows:—

The extension to the Windsor Depot. This comprised an enormous amount of work. The addition was on the down-hill side of the original Windsor Depot, extending for about a block, the lower end resting upon St. Antoine Street, and the frontage all the way along being on Windsor Street. The St. Antoine Street end of the building had to be a couple of stories higher than the original building in order to bring the roof in line from end to end. The building is not yet completed and some nice engineering problems were involved.

Two very fine buildings undertaken by Lyall & Sons this year were the Transportation Building and the Dominion Express Building. These are two of the largest office buildings in Canada, the former being considered the largest. In the construction of this building it is likely that a record was made. The contractors only obtained possession of the site on the 1st of May. It took three weeks to remove the buildings thereon, and by the middle of August the excavation had been performed and the steel structural work, comprising 3,000 tons, completed. Meantime, the bricklayers and masons had begun work on the 24th of June and by the 11th of September the entire building, ten stories in height and covering a block, was roofed in and ready for the interior work. During this period, 30,000 cubic feet of stone and 1,250,000 brick had been put in place. Just across the corner, work was being proceeded with, simultaneously, upon the Dominion Express Building, on the site of the old St. Lawrence Hall. Some difficult engineering problems were here carried out also, the Foundation Company have done some very interesting work on the concrete piers, the same company having also carried out work on the Windsor Station, referred to.

Macdonald Physics Building, McGill University.
View from Southwest. Mr. A. T. Taylor, Architect.

Other big buildings carried out by Lyalls during the last couple of years were the Yorkshire Building, just across from the Dominion Express; the Technical School up on Sherbrooke Street and the Willis Building on St. Catherine Street.

Other big buildings now in course of construction are the Ritz-Carlton Hotel on Sherbrooke Street, by the Fullet Company. Nearly opposite it the new Art Gallery, a beautiful building of classic architecture, is being constructed by the same company. Several reinforced concrete buildings of the skyscraper type—which in Montreal is confined to ten stories—have been constructed in the upper section of the city during the past few years. Probably the first and one of the finest and largest, is the Jacobs Building, on St. Catherine Street. The Blumenthal Building on the same street, farther east, and the Kellert Building, yet farther along, as well as the Wilder Building on Bleury Street, nearby, are all buildings of much the same character, constructed during the past few years. These mark the progress of the building in the city and more especially the transition of the uptown section from the two and three story era into the eight and ten story era. Practically all these new reinforced concrete and other sky-scraping structures involve engineering problems, particularly along certain sections of St. Catherine Street, where the nature of the ground necessitates going to solid rock in order to obtain safety.

Montreal has practically solved its great harbor problems. For years this was the one thing Montreal talked about. A dozen or thirteen commissioners used to gather down at the harbor office and discuss ways and means. Meantime the ships came to an antiquated harbor. The wharves were constructed of wood and the sheds of the same material. Owing to the high water and ice shoves of the early spring, it had been found necessary to construct a dyke all along the harbor front, with openings for access to the wharves below. Each fall all the buildings on the wharves and the wharf levels on the harbor front had to be pulled down and piled away in such a manner that they could be erected again the following May. When the ice began breaking up in the spring the openings in the dyke were closed in by gates in order to prevent the lower part of the city from being flooded when the ice shoves began. Until the ice jam in the river below broke and allowed the waters to subside not a sign of the wharves could be seen along the whole harbor front, the river being high above them. When the water fell, tons upon tons of ice would be left piled high all over the wharves. There were no grain elevators of consequence along the harbor front, and the loading was done mainly by floating grain elevators, operating on barges or lake steamers loaded with grain and moored alongside the out-going steamer.

Half a dozen years ago the old Harbor Board, which spent its time mainly fighting, was dispensed with and the work was handed over to a commission of three. Since that time the most wonderful progress has taken place along the harbor front. High level wharves of a permanent character have been built, and practically indestructible and fireproof sheds have been erected upon them. The capacity for docking ships has been largely increased, and as the sheds are two stories high their capacity for freight accommodation is several times that of the old sheds. Goods are stored here throughout the entire winter. The dyke is constructed of stone. Several modern grain elevators, two of which are the property of the harbor commissioners, have been built along the harbor front. These are being added to by the commissioners as quickly as possible. Conveyor belts carry the garin to the ships at almost all points in the centre harbor. The commissioners have their own locomotives for handling cars along the harbor front, and a proper system of tracks and switches lead down between the lines of sheds on the different piers. Floating cranes, with enormous lifting capacity, and devices of all kinds for the rapid loading and unloading of vessels have been installed. Meantime, also, the deepening, widening and buoying of the ship channel between Montreal and Quebec and below have been carried out, until ships may proceed by day or night with reasonable safety. Accidents in the channel are now almost unheard of.

The programme of the commissioners, however, is by no means completed. Comprehensive plans covering ten or twelve years' work were laid down shortly after they took office, and when these have been carried to completion Montreal will be—as it is to a large extent now—one of the best equipped ports in the world.

While, heretofore, the principal engineering problems in the vicinity of Montreal have probably been in connection with the harbor and channel, other problems are now arising which will undoubtedly claim a large share of attention during the next decade or two. A means of rapid transit throughout the city of Montreal and connecting up with points outside the city must quickly be devised and the problem will call for the exercise of the greatest skill and ingenuity. The south shore must be connected up with the city, by means of a bridge or tunnel, or partly by bridge and partly by tunnel, the Grand Trunk bridge above the city being inadequate for the general purposes of the citizens. Whatever method is employed accommodation must be provided for foot passengers and for the passage to and fro of street cars and vehicles of all kinds which may require access, and in addition thereto must be provided accommodation for the various railways which approach Montreal from the south. Consideration is already being given to this undertaking, but the problem is a very difficult one, and it is impossible to say how it will be solved.

Equally important is a means of rapid transit within the city itself and a more rapid approach to the heart of the city, both for street cars and for passenger trains, more especially from the west and from the north. The problem becomes all the more difficult because of the location of Mount Royal, immediately back of the city. Ere many years, the city will have extended completely around the mountain. In fact, it may already be said to have done so; and it is the growing needs of the residents of the outlying districts to reach the centre of the city, which is occasioning the present clamor for more rapid transit.

Many suggestions have been made respecting quicker transit in the city itself. Chief among these is the subway project. Nothing definite has yet been proposed, but there is talk at the present moment of applying to legislature for the right to construct a subway or tunnel, and to operate municipal street cars therein. Included in the same discussion is the question of permitting the operation of motor busses on the different streets.

Of a more immediate character than any of the above, however, would seem to be the problems raised by the Canadian Northern Railway. Precisely what it is the intention of the Canadian Northern Railway to propose to the city is not yet known. The railway, however, intends to take the matter up with the city at almost any moment, and ere this article appears will probably have done so. Meantime, it is commonly reported—and there is every reason to accept this report—that the railway has purchased a site for depot and terminals adjacent to the present quarters of the Canadian Society of Civil Engineers, which is a short distance east of Dominion Square, and within a few minutes of the C.P.R. Windsor depot. How the C.N.R. proposes to reach its new terminal is the interesting question. The most-talked-of

means is through a tunnel to be constructed under Mt. Royal. It is understood that the tunnel would enter the mountain immediately in rear and come out at the new depot, a distance of probably three miles through. This would undoubtedly be the quickest means of access to the city which has yet been considered. An alternative proposal is entry by means of a viaduct. From its depot the C.N.R. would make connections with the harbor front by means of an elevated track.

Work on the Highlands Side of the River.

All this brings up the equally important point of motive power. The citizens are becoming tired of breathing tons of coal dust. Scores of locomotives are constantly puffing to and fro, making discordant noises and emitting volumes of smoke, the unpleasantness of which need not be described. It has already been proposed that both the C.P.R. and G.T.R. should electrify their systems in order to place themselves in a position to discard their smoky locomotives. The C.P.R. has probably declined; but of course it is only a matter of time until it will have to give its assent. Fortunately, Montreal is well supplied with power. The Montreal Light, Heat & Power Co. has contracted for at least 30,000 h.p. more than it is making use of at the present moment, and no doubt it could add yet 50,000 to this if necessity arose. The Cedar Rapids development is now going on. From this will be drawn 50,000 h.p. on the first installation, and yet other installations are to be added. Several other water powers of a minor character are located within commercial distance of the city. The promoters of the Long Sault dam project promise hundreds of thousands of horse-power for Eastern Ontario and Quebec. It would, therefore, seem that there need not, for a long time to come, be any trouble in obtaining all the hydraulic development necessary to operate the industries of the city, and to electrify the various railway terminals.

It is estimated that by 1920 Montreal will have over 1,000,000 inhabitants. There seems no reason at present to doubt that this prediction will be fulfilled. Industries of all kinds and with enormous requirements for employees are being added year by year. Undertakings of a magnitude undreamed of until lately are calling for immediate attention. Railway and canal construction, harbor and river improvements, rapid transit requirements, hydraulic power construction, underground conduit systems for the reception of overhead wires, better electric lighting and telephone service, more efficient fire protection, including proper provisions for the construction of modern fireproof buildings; increased water supply and a filtration system on a large scale, sewage disposal—all these are problems which Montreal is now facing or will have to face within the next few years. There is work for the engineer.

NEW FOUNDATIONS FOR THE C. P. R. LACHINE BRIDGE.

In the finishing of the foundations for the above bridge on or about December 1st of this year, the heaviest piece of construction encountered on the Farnham Section of the Canadian Pacific Railway in its double tracking, is completed.

The old bridge was located about two miles above the well-known Lachine Rapids, and was a single track structure 3,657 ft. 6 in. long between abutments, with three 80-ft. deck plate girder spans, one 120-ft., two 270-ft. and eight 240-ft. deck truss spans, and two through truss spans about 408 ft. centre to centre of piers, supported on two abutments, two land piers, and thirteen river piers. The work of extending the lines to accommodate the double track of the bridge involved the extension of the existing piers and abutments, and the construction of four new river piers to allow the replacing of four of the original 242-ft. spans by eight 121 ft. spans.

All of the new piers and the extensions to the old, are of rock-faced limestone ashlar with concrete footings carried down to bed rock, at a maximum depth of 37 ft. below water level. This bed rock was covered with from three to sixteen feet of gravel and large boulders, and large bodies of riprap deposited from time to time around old pier.

A current of from eight to ten miles per hour had to be contended with, and the force of the current can be better appreciated by the fact that the pressure against the caissons for the deep water piers was estimated to be no less than 100 tons.

For the construction of the four new river piers, open cofferdams with puddled walls were used. The overlying sand and gravel was dredged off and the cribs, after being carefully fitted to the irregularities of the rock bottom, were sunk in the required position. The rock in puddled chamber was then cleaned off with divers. Sheeting was driven and the space between the two walls filled with puddle clay. The cofferdam was then pumped dry, permitting the rock to be cleaned off and the concrete deposited in the open.

C.P.R. St. L. R. Bridge. View of Piers on Highlands Side of River, Just Before Steel was Placed on the Down-stream End.

With the exception of seven of the piers, where the water was deep, the extensions to the existing piers were made in substantially the same manner. The cribs for these were closed in on three sides only and so arranged that the sides would overlap and fit closely against the old cofferdams used in the original construction of the bridge which had been left in place. After these joints had been carefully caulked by

divers, and the cofferdam walls puddled with clay, no difficulty was experienced in unwatering with 8-inch centrifugal pumps. Practically all of the leakage came from open joints in the old cofferdam.

The foundations for the extensions to the seven remaining piers, where the depth of water was from 20 to 27 ft., were carried down to rock by a combined pneumatic and open process. In order to reduce the current from 8 to 10 miles an hour, to about 2 or 3 an hour at each of the seven piers above mentioned, breakwaters were constructed on both sides of each old pier.

Showing Erection of Channel Piers.

A derrick boat equipped with grapples and an orange peel bucket were then used in removing the riprap and boulders to allow the pneumatic caissons to rest on a comparatively level bottom when they were sunk.

The pneumatic caissons were constructed of long leaf yellow pine. The walls were heavily cross-braced in the usual manner. A single shaft with the contractor's standard type of air-lock was used for both men and material.

It is customary to build caissons for river work on the shore, launch them in the usual manner, then tow to position. On account of the heavy current at this bridge site, it was considered advisable to build each caisson in place. Accordingly, the contractors constructed a pontoon of sufficient size to sustain the caisson without drawing more than a few feet of water. As fast as they were required for the work, the caissons were constructed in this pontoon and anchored with steel cables to existing piers. The temporary bolts in the pontoon were then withdrawn, allowing the pontoon to fill with water and the pontoon pulled from under the caisson as it settled in the water.

After a caisson was launched, the same pontoon was towed to the next pier. When launched, the caisson was located and was sunk to bottom of river. Walls of caisson were built up and caulked as caisson went down.

All pneumatic caissons were sunk at the end of the footings of old pier, which were rectangular in shape. There was therefore left two triangles to be filled up between pneumatic caissons and old foundations of old pier. These triangles were dredged out as near solid rock as possible, then a cofferdam was built on each side of extension attached to pneumatic caisson on one end, and old footing on other. Divers were then sent down to clean off bed rock. Concrete was deposited under water in the triangles for a few feet by means of a special submarine bucket. This cofferdam was then pumped out and huge I beams were then placed in concrete, one end resting on pneumatic caisson and the other on the old pier. All was then concreted to the elevation where the masonry started.

Material for piers Nos. 3 to 7 inclusive, where the water was shallow 4 to 10 ft., was delivered to the work by means of a tramway 1,000 ft. long. Derricks were attached to old bridge and two derrick boats used also.

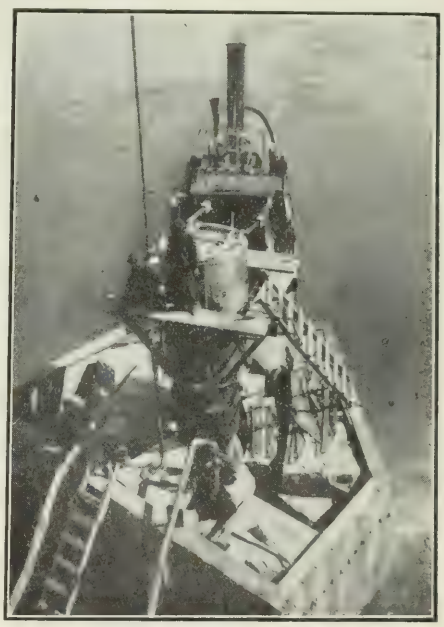
Material for piers Nos. 8 to 14 inclusive, was delivered to each pier from the south shore by means of scows and a tug. A large material yard with the necessary switching tracks connecting with C.P.R. main line and buildings built on south shore and a temporary deck built also.

Power house containing compressors, boilers, pumps and dynamo, was located on south shore. Air line was laid on old bridge.

The contractors for the substructure used the following plant on the job: 2 derrick scows, 1 concrete mixing scow, 7 material scows, 1 tug, 12 hoisting engines, 350 h.p. boilers, 2 concrete mixers, 12 derricks, 3 compressors, besides pumps, dynamo, etc.

Work was commenced in July, 1910, and finished December 1st, 1911.

The great difficulty in doing this work was principally in building and sinking caissons, and in moving scows, row boats and tugs around in the swift 10-mile current. The current was not uniform as the obstructions in the river made by the old piers produced a series of eddys, cross-currents and whirlpools. Even in deep water there were a lot of boulders lying near the surface. Operating floating equipment around in such a locality was an operation fraught with danger to both life and property.



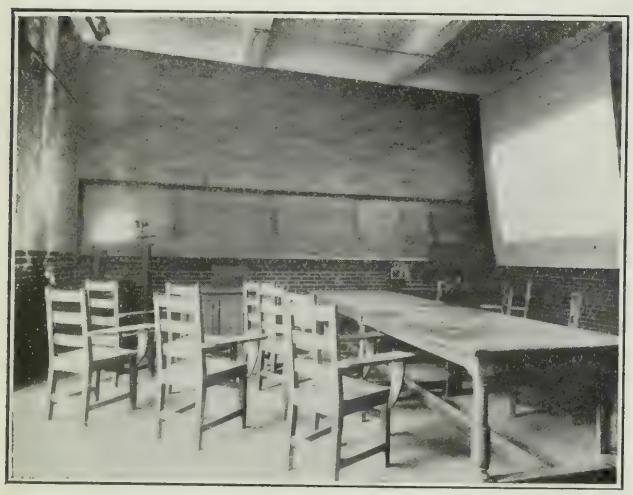
Sinking a Pneumatic Caisson at Down-stream End of One of Channel Piers.

The contract for the new substructure of the bridge was executed by The Foundation Company, Limited, of Montreal, under the supervision of Mr. J. M. R. Fairbairn, assistant chief engineer of the Canadian Pacific Railway. Mr. J. H. Barber was resident engineer on the work.

McGILL UNIVERSITY, COURSES IN THE FACULTY OF APPLIED SCIENCE.

By E. BROWN, M.Sc., M. Eng., Professor of Applied Mechanics and Hydraulics, McGill University.

The name of McGill University is known throughout the world, and not a little of the prestige of the city of Montreal is due to the great university, which occupies such a prominent position in its midst. The eminence of McGill in many branches of learning is well known to all our readers, but the work of the Faculty of Applied Science in training the young engineers who are going out to contribute to the progress of the Dominion is of special interest. The annual meeting of the Canadian Society of Civil Engineers, which takes place in Montreal shortly, will doubtless attract many of our leading engineers, and it seems appropriate to give some account of the work of McGill University in which they will find the greatest professional interest. We do not propose to give a history of the rapid development of the Faculty of Applied Science, interesting though that would be, nor to set forth the details of the numerous courses offered, but rather to explain in some measure the aims and objects of the training given, no matter what branch of the profession a student may enter. To this end it will be necessary to describe the training common to all courses, and then to proceed to show



Lecture Room, (Railway Department.)

its logical development in some special branch of engineering. Our readers will thus be able to realize more clearly the continuity of the work than if several courses were described inadequately. The particular features of the various specialized courses will be pointed out, after the general scheme of one course has been followed to its conclusion.

It is a striking feature of the work that the undergraduate body is drawn from all parts of the world, and this fact, in itself, bears eloquent testimony to the high position which the engineering school occupies in the academic and professional world. Of a total of 555 students enrolled in the present session, only 257 come from the Province of Quebec, and the remainder are distributed as follows: Ontario 108, Nova Scotia 17, New Brunswick 22, Prince Edward Island 11, Manitoba 12, Saskatchewan 5, Alberta 12, British Columbia 22, Newfoundland 4, England 31, Scotland, Ireland and Wales 2 each, British West Indies 15, United States 17, Mexico, Peru and South Africa 2 each, Republic of Colombia, Ecuador, Italy and Switzerland 1 each, unclassified 6. The graduates of McGill are likewise scattered all over the world, and occupy the highest positions in the profession. The name of McGill is thus widely known, and the courses attract not only those commencing their college training, but many who have graduated in other universities and find it advantageous to take an additional course of study and a degree in McGill University before commencing the practice of the profession in Canada. In this list may be included graduates of Cambridge, Edinburgh, Liverpool, Manchester and other well-known universities.

Courses of study extending over a period of four years and leading to the degree of Bachelor of Science are offered in the following ten subjects:—

Civil Engineering.
Electrical Engineering.
Mechanical Engineering.
Mining Engineering.
Railway Engineering.
Metallurgical Engineering.
Chemical Engineering.
Chemistry.
Metallurgy.
Architecture.

Seven of these subjects bear the distinctive title of "engineering," and in all of these the course of study is the same in the first two years. These courses will be considered first, and the courses in chemistry, metallurgy and architecture later. In all courses the work of the session extends from about September 1st to the end of April, thus leaving the summer months free for the student to engage in practical work.

Engineering Courses.—The fundamental principles underlying the various courses of study are as follows:—

(a) That a thorough grounding in mathematics, geometry, mechanics, physics, chemistry, and the elements of draughting, is essential to intelligent study in any branch of engineering, and in conjunction with the general and specialized work which follows, enables a student after graduation to adapt himself to the requirements of the various branches of the profession, if called upon to do so.

(b) That having had such a preliminary training, all engineering students require professional training in certain subjects, such as strength of materials, the elements of mechanical and electrical engineering, and surveying, coupled with specialized training which will fit them for some particular branch of the profession.

(c) That the professional training common to all branches of the profession should precede the specialized training of any one branch, so that the student may have as broad a view of these studies as possible, and that a considerable amount of time may be spent as continuously as possible in the specialized studies.

(d) That no subject of study in any course should be undertaken unless the student is properly qualified by previous study to appreciate the work, and to pursue it in a manner which will make it of real educational value to him, and not merely the opportunity for collecting a few disconnected ideas. This is ensured by a scheme of pre-requisites.

First Year Study (All Engineering Courses).—This includes algebra, trigonometry, geometry, mechanics, descriptive geometry, physics, English, freehand, mechanical drawing and shopwork.

Practically one-half of the total time is devoted to the first five of these subjects, these being regarded as of supreme importance in the course of fundamental training. The progress made in this work is tested from time to time during the first term, and although the final standing is not determined until the end of session, the regulations compel any student whose progress is unsatisfactory in any four of these subjects to withdraw from the faculty at the end of the first term. The class is thus freed automatically of any, who, either from incompetence or lack of application, are failing to profit from the instruction given, and are thereby imposing a needless burden, both on the instructors and on their fellow-students. The operation of this rule has a salutary effect and accustoms the class to the idea underlying the scheme of instruction as regards pre-requisite knowledge.

The course in physics, dealing with heat, light and sound, includes laboratory work, in which experiments, **mainly quantitative,** are made to illustrate the subject matter of the lectures. This is an important point, as engineering students spend much time in making quantitative measurements in the various laboratories, and in the practice of their profession. Such measurements are made frequently under difficulties and in circumstances in which errors must arise. It is well that in the preliminary scientific work a student should learn to appreciate the conditions for precise measurement, and to realize the relative importance of accuracy of measurement of the various quantities involved, in considering the probable degree of accuracy in the result they are seeking. Not only must an engineer know the probable degree of accuracy of his results, but he must be able to present them in a consise and accurate manner. The course in English composition is designed to stimulate ease and directness of expression, and in the preparation of reports on laboratory work carried out during the full course of study, and in the writing of theses on summer work, the student has an excellent opportunity for practice in the handling of available material. The course in English includes the reading of some five or six English classics during the first summer vacation, on which an examination is given on entering the second year.

The courses in shopwork, in the first and second years, are designed to give the student some working knowledge of materials and of methods of manipulation. Thorough manual skill can only be obtained by longer practice in engineering shops, but an endeavor is made to familiarize the student with shop equipment and methods, so that he may profit as much as possible by working in engineering shops later on. At the same time those who do not work in this way are not altogether devoid of sound ideas on such matters. Definite exercises are carried out in the first year course, in carpentry and wood turning, and in the smithing and foundry, and in the second year similar work is done in the metal workshop, and students are instructed in the use of the various machine tools, and in the preparation and care of tools.

The courses in freehand and mechanical drawing are designed to familiarize the student with sketching, and with the methods of preparing working drawings. Drafting room methods are explained and practice is given in the drawing of simple machine details, in lettering, and dimensioning of working drawings, etc.

After completing the course outlined above, the students leave about the end of April, the great majority obtaining work for the summer vacation. Some details of this work are given later, but it may be mentioned here that during last summer 85 per cent. of the students in Applied Science worked for an average period of 3.2 months.

All students entering second year courses are required to return to Montreal for the month of September to take a course of field instruction in the principles of surveying, as a preliminary to the work in that subject noted below.

Second Year. (All Engineering Courses).—The work in mathematics, mechanics, physics, mechanical drawing and shopwork are extended, the mechanical drawing course with a view to preparing the student for design work of the third and fourth years, and the shopwork as already noted.

In mathematics, courses in the calculus are given and are of the highest importance in the work of the year, being prerequisite to much of the late work. A course in analytic geometry is also given. The work in mechanics is done after progress has been made with the calculus course, and the work of the first year is extended to include many problems in variable motion arising in engineering practice. It may be pointed out that mechanics is taught as a separate subject through three years, and not as a part of the various professional subjects (such as mechanics of machines, dynamics of machines, strength of materials, etc.), to meet the bare requirements of any particular problem. The work is brought to bear directly on the professional subjects by carefully selected problems, and this adds interest to the work in mechanics, and minimises the amount of purely extraneous teaching in professional subjects.

The physics of the second year deal with the laws of electricity and magnetism, the laboratory work including quantitative measurements of magnetic fields, pole strength, current, resistance, potential, etc., and the calibration of measuring instruments. It thus provides the preliminary training required for a study of the elements of electrical engineering, which is taken as a part of the professional

Wood Workshop.

work by all students, for there is scarcely any phase of engineering activity at the present day, in which electricity does not play an important part.

The lectures and laboratory course in general chemistry familiarizes the student with the principles of inorganic chemistry, and gives some practice in qualitative analysis. It is desirable for all engineering students, and especially for those who intend to specialize in metallurgical, chemical or mining work. Concurrently with the chemistry course, a course on materials of construction is given, dealing with the principal methods of manufacture of steel, iron, the chief metal alloys, cement, etc. The uses of these materials, and of timber, masonry, etc., are considered, and some typical standard specifications are discussed.

As a preliminary to some of the third year work, courses in mechanics of machines and graphical statics are given.

The field surveying work carried out before the opening of session has been referred to above. It forms part of a

general course in the principles and practice of surveying, and includes the ordinary problems of chain surveying, the use of the level, theodolite, compass, etc. Detailed surveys are carried out and recorded, and the data so gathered are used in the preparation of detailed plans in the mapping course. The problems arising in ordinary practice are dealt with in a lecture course, and in this way a comprehensive idea is given of the field and office work necessary in the preparation of a surveyor's plan.

The students are again free at the end of April to take up practical work for the summer months, but are again required to attend a summer school course of four weeks before commencing the work of the third year. The work undertaken depends upon the branch of study which the student desires to enter upon, and is as follows:

(a) Field surveying for students in civil, mining or railway engineering.

(b) Mechanical drawing and design, physics, (including more advanced electricity and magnetism, and electrical measurements than that given in second year), and shop-work for students in electrical and mechanical engineering.

(c) Qualitative and quantitative chemical analysis for students in metallurgical engineering.

In addition to the above, all students are required to prepare an essay, preferably upon their summer work (or upon some prescribed subject), or to follow a course of reading in which an examination test is given. These essays are a distinctive feature of the work, and frequently reveal decidedly strong powers of observation. A similar requirement is exacted of students entering the fourth year, and many excellent essays result. Credit is given for excellence of material, successful presentation, originality, and literary style, and no essay prepared merely from books is accepted unless special permission has been granted. The high standard of many of the essays may be judged from the fact that very frequently a similar essay secures the prize given for papers presented by student members to the Canadian Society of Civil Engineers, the Canadian Mining Institute, etc. The class of work secured by students during the summer months and their ability to make good use of the opportunity afforded, are shown by the fact that it is no uncommon thing for a student to be refused permission to publish certain parts of an essay—such for example as cost data.

Mechanical Engineering Laboratory.

As an example of the summer reading prescribed instead of an essay it may be stated that Shadwell's "Industrial Efficiency" was the set book for the past year.

Third and Fourth Year Courses.—Having completed the above course, the student must choose some branch of engineering in which to specialize, and complete two years of further study. The whole of this time is not spent in specialized work, as all courses have certain professional subjects in common, such as strength of materials which is the basis of many calculations in all branches of engineering. The elements of mechanical and electrical engineering are also common to all courses. Alternative subjects are allowed in some fourth year courses. For example, one electrical engineer may wish to study electro-chemistry and electro-metallurgy, while another, more interested in power development, may wish to take up hydraulics. Provision is made for the exercise of such legitimate preferences, but the greater part of any course is fixed, so that a sound general training is assured. With seven engineering courses to be considered and many alternatives in each, it will be seen that no connected idea of the progress of the scheme of study can be given within reasonable compass, by attempting to describe all courses. Selection must be made, and for present purposes, the specialized work of the civil engineering student will be considered. The trend of the course of study in other branches will then be indicated.

The work of the civil engineer requires that he be specially informed upon such subjects as the strength and testing of materials, theory and design of structures, surveying, hydraulics, railroad engineering, etc., and the third and fourth year courses afford the training necessary.

Third Year Course (Civil Engineering).—An important part of the course is the study of strength of materials and the allied subjects of foundations and structural design, Lectures in strength of materials are given throughout the session, and laboratory work is added to familiarize the student with the various types of testing machines and method of testing. The students themselves carry out all the tests made to illustrate fundamental principles, and also make complete tests of cement, following standard specifications. They also witness demonstrations on the strength of timber beams, reinforced concrete, reinforcing materials, bricks, concrete, etc., and prepare reports on all laboratory work. (This course is taken by all engineering students.)

A lecture and draughting course in foundations runs concurrently with the strength of materials, work, and, as progress permits, simple designs are carried out. The graphical statics work of the second year is made use of in such problems as the stability of retaining walls. Practice is given in taking out quantities from working drawings and in preparation of cost data, and relative costs of alternative designs are considered in some simple cases. This work is only taken by civil engineering students, and is completed in the first term. The progress with strength of materials work then enables the course in structural engineering to be started, and this is also taken by all except electrical engineers. A combined lecture and draughting course deals with the design and structural details of columns and girders (as for a steel frame building), roof trusses, box and plate girders, reinforced concrete beams and columns, etc. Working drawings, with bill of materials, and cost estimates, in some cases, are prepared, and the student becomes familiar with much of the ordinary day to day practices. The course affords the necessary preliminary training for the more advanced design of the fourth year civil engineering course and gives to the students the necessary acquaintance with the elements of structural practice.

Another important group of subjects is surveying, railway engineering and mapping, for which the summer school work in surveying, already mentioned, is a prerequisite. This includes practice with and adjustments of level and theodolite, survey and location of a railway line; hydro-

graphic work, including measurement of river discharge; astronomical observations, etc. The data thus collected forms the basis of the subsequent mapping course in which the paper location of a railway line is drafted from the notes, maps and profiles are drawn, earthwork quantities taken out, etc. A yard and switch design is also made and drawn out. Concurrently with the mapping course and supplementing the work done in the field, lectures are given in railway engineering dealing with grade problems; effect of distance, grade and curvature on train-mile costs; economics of location; turnouts, yards, terminals, etc. The above work is taken by civil, railway and mining students. Students in the civil course take also a course of lectures in surveying dealing with the theory and use of instruments; mining, magnetic, hydrographic, trigonometric surveys; transition curves, etc.

Instruction is given in municipal engineering problems, and is continued in the fourth year. The third year work includes systems of removal and treatment of sewage; construction of sewers; field and office work in the preparation of plans, cost data, etc.; construction and maintennance of roads. This special work and that of the fourth year is in charge of an instructor engaged in municipal engineering practice.

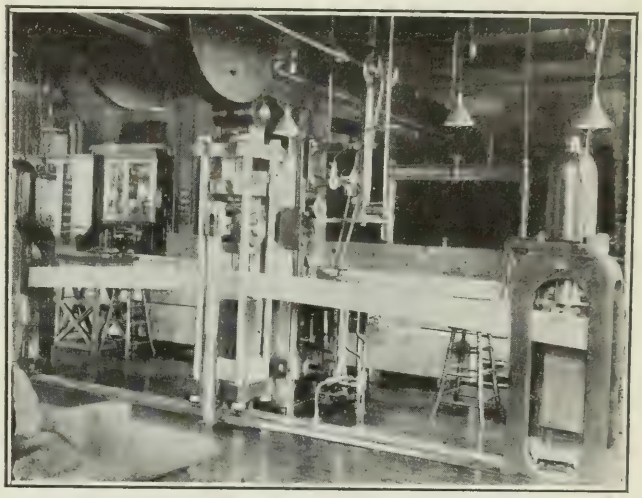
A course in mechanics dealing with the motion of rigid bodies is also given. Geology is treated in a course which is taken also by mining, metallurgical and chemical engineers. The course is a general one, including some mineralogy, and special attention is devoted to dynamical and historical geology and to the economic aspects of the subject. Field excursions are made in the neighborhood of Montreal, and practical instruction is given in the museums and by the aid of maps and models.

The remainder of the course includes (a) descriptive geometry dealing with perspective, plotting a photographic survey; spherical projection and map construction; (b) engineering economics including the subjects of money, credit, formation and organization of business companies, operating and fixed charges; specifications, contracts, etc.; (c) general course in mechanical engineering with laboratory work, dealing with the equipment and operation of power plants; (d) an optional course in differential equations.

The above concludes the work of the third year, and with the exception of elements of electrical engineering taken in the fourth year, along with electric railways, it may be said that the general professional work is completed, leaving the fourth year almost entirely free for more advanced study of those civil engineering subjects taken up in the third year, and for other specialized work. Summer work may again be obtained from the end of April to the end of August, the class being required to attend four weeks field course in surveying in September, after which the work of the final year of study commences. Students must also submit an essay of from 2,000-5,000 words, consisting preferably of a critical description of the work in which they have been engaged during the summer.

Fourth Year Course (Civil Engineering).—The specialized work of the final year falls into groups of subjects more or less related: (a) Theory and design of structures; (b) surveying; (c) hydraulics and municipal engineering (water supply); (d) railway engineering and electric railways, and a general course in elements of electrical engineering. In the theory and design of structures, the aim is to explain the fundamental principles of the determination of stresses in various types of structures, to apply the principles of strength of materials to the computation of the necessary dimensions of the main members of structures, and to develop a considerable knowledge of the detailing in design work. To this end, lecture and draughting work is taken concurrently, the latter bearing directly on the former, and as the work progresses designs for selected types of bridges are worked out in considerable detail, and working drawings are prepared. A large part of the time available is devoted to this form of practice, as it is thought that a sound knowledge of bridge design evolved from fundamental principles is the most suitable form of training for the whole field of structural design. A course in reinforced concrete dealing with the design of floor and column units for a large building, retaining walls, arches, etc., is also given, and includes draughting room work and laboratory tests on reinforced beams.

The work in surveying carried out in the summer school includes astronomical observations for latitude and longitude; base line measurements; precision levelling, special problems in track work, etc. This is followed by a course of lectures dealing mainly with the reduction of astronomical observations, measurement of base lines, large triangulation surveys, etc., and by a laboratory course in which instruction is given in the determination of errors and constants for surveying instruments in general. This completes the comprehensive course in surveying work which commenced in the second year.



Testing Laboratory, Beam Under Load in Wicksteed Testing Machine. Capacity 200,000 lbs.

In the hydraulics course the fundamental principles are developed and applied to problems on the flow over weirs, in pipes and open channels.. Turbines, pumps and other hydraulic machines are considered, the endeavor being in all cases to treat the problems from elementary principles, which enable the characteristics of various types to be understood. Concurrently with the lecture course a series of laboratory tests is carried out to illustrate the more important principles of the subject. The work of the municipal engineering course deals with problems in water supply and includes discussion of rainfall, evaporation, works for storage and distribution; purification; calculations for systems of supply mains, preparation of plans, costs, etc.

Problems in railway engineering practice which border on civil engineering work are dealt with, and include the organization of an operating department, construction, maintenance, renewals, train service, signalling, etc. The course supplementing the work of the third year in railway location, etc., gives a good foundation for more extended study, if a student is thrown into contact with such work.

A course in engineering law is given, the object being to present such an outline of the law as will be useful to engineers and business men. The main topics discussed are the general law of contracts; law of architect and

builder; statutes affecting labor; commercial paper; sale; lease; agency and partnership; joint stock companies; insurance carriers by land and sea. All students in the Faculty except electrical engineers take the lectures either in their third or fourth year course.

The remainder of the course is electrical in character and includes a series of lectures on the principles of direct and alternating current machines, systems of distribution of power, lighting, traction, etc. A laboratory course is given to supplement the lecture work, and when some progress has been made with the subject, a course in railway engineering dealing with the equipment, maintenance and operation of electric railways is added.

The student who passes successfully through the course described is granted the Degree of Bachelor of Science in Civil Engineering. It will be seen that a continuous endeavor is made to give a sound general scientific training, introducing specialization to a sufficient extent to ensure that a successful student may enter on the practice of the particular branch of the profession in which he has studied, well equipped to avail himself of the opportunities offered. At the same time the general training given is sufficiently broad to give him a good grip on subjects outside the strict limits of his own special branch of work, and to enable him to deal intelligently with problems in other branches of engineering which inevitably arise in the practice of any particular branch of the profession.

Specialized Work in Other Engineering Courses.—The above account of the work of the civil engineering course illustrates the principle underlying the development of the courses of study in all branches of engineering. After the training of the first and second years, which is the same for all students, and is mainly of a mathematical and general scientific character, the third year study includes professional work common to all students, viz., elements of mechanical and electrical engineering, structural engineering, strength of materials, etc., and some specialized work, professional or scientific, leading up to the more advanced work of the fourth year. The differences in training noted in connection with the summer school work, preceding entry to the third year, emphasise this specialization. We may note briefly some of the principal features of courses other than the civil.

On entering the third year the electrical student continues his study of physics, takes a more complete course in the elements of electrical engineering than that given to the general body of students, studies machine design instead of structural design, and if he is contemplating specializing in electro-chemistry and electro-metallurgy in his fourth year, an introductory course in this work is prescribed for the third year. Following this specialization the work of the fourth year develops along the same lines.

The student in mechanical engineering prepares for the specialization of the fourth year by taking a more complete course in mechanical engineering than that given to the general body of students, and studies problems in mechanism, thermodynamics, machine design, shop processes, etc. In the fourth year more advanced work follows, and such subjects as manufacturing, plant design, heating and ventilation, locomotive engineering, works organization, and accounting may be studied.

Metallurgical and mining students prepare for their fourth year by taking courses in quantitative chemical analysis, mineralogy, geology, and the subjects of ore dressing, fire assaying, metallurgy, and general mining are commenced, and are more fully developed in the fourth year. A special feature is the field class in mining, which all students of the course must attend. This consists of a six weeks duration, following the close of the third year work in college, and places of professional interest are visited, the party being in charge of the staff of the mining department. Time is devoted to geological field work, mining work proper, and to an examination of ore dressing and milling plants. It may be of interest to note that these parties have visited at various times British Columbia, Nova Scotia, Pennsylvania, Newfoundland, Michigan, and numerous places of interest en route to these distant points.

Metallurgical engineering students make similar visits to manufacturing plants in Montreal and at a distance, and a short lecture course is given in exvlanation of the processes to be studied.

The course in chemical engineering is designed to prepare the student for the duties of a managing engineer in a chemical factory. He must have some general engineering training and be conversant with chemical processes. The course includes the general work specified above for all engineering students, and a special summer course in chemical analysis precedes entry to the third year. Other subjects of study include geology, metallurgy, organic and inorganic chemistry and industrial processes with special reference to the branch of work to be taken up. Between the third and fourth years at least six weeks must be devoted to suitable work in a chemical factory or to equivalent laboratory work in the university.

Courses in railway engineering prepare students to enter (1) the operating department or executive offices; (2) the mechanical department; (3) the engineering department.

The Canadian Pacific, Grand Trunk, Canadian Northern and Intercolonial railways contribute to the support of the work of this department. Arrangements exist whereby students may enter the employment of a company during summer vacations as special apprentices. They thus acquire, under the direction of the officials of the company, a general experience which will fit them to fill higher positions after successful graduation. Full particulars of these arrangements are given in the Bulletin of the Department of Railways.

Students preparing to enter the mechanical department follow the same course as mechanical engineering students, but make a special study of locomotive construction and operation as part of their specialized work. Those entering the engineering department take the regular civil engineering course, but are required to engage in practical railway work during the summer months under the direction of the department of railways.

The operating and executive course includes, in the third or fourth year course of study, much of the general work common to all engineering courses (strength of materials, electrical and mechanical engineering, etc.). In the third year includes a more advanced course in economics than that given to the general body of students, and this is followed by a special course in railway economics in the fourth year. Courses in engineering law and in railway law are also given, and courses in English afford practice in the preparation and criticism of reports on stated subjects. Railway organization and accounting, freight and passenger service, and telegraphy are dealt with by officers of the railway companies engaged in these departments of work, and the course also includes instruction in railway mechanical engineering (locomotive design, operation, etc.), railway engineering (grade problems, train costs, economics of location, layout of terminals, yards, etc., organization of operating department, construction and maintenance of way, etc., etc.); railway operation and systems of signals; physical geography and shorthand.

The work of the department is developing steadily, and while it is not numerically as large as many of the older de-

partments, the success attained by many of its graduates who have entered the service of the companies which are co-operating in the work, proves that the work is developing along sound lines, and that the course affords the opportunity for efficient training along specialized lines outside the older recognized branches of the profession.

Courses in Chemistry and Metallurgy.—These differ from the chemical engineering and metallurgical engineering courses in that they are intended to train men for the purely scientific side of such work, i.e., to become analysts, or chemists, or metallurgists in a manufactory. Such engineering subjects as strength of materials, mechanical and electrical engineering, etc., are not taken, and the time devoted to these in the engineering course is given to more advanced study in chemistry and metallurgy. The general preliminary training resembles that of the engineering student, but the specialized work is purely scientific.

Course in Architecture.—Four years of study in the Department of Architecture lead to the degree of Bachelor of Architecture, and an increasing number of students are availing themselves of the facilities offered to secure a thorough grounding in those principles of architecture which tell later on in a professional career. The work done is also recognized by the Province of Quebec Architects' Association in that a graduate in architecture will be admitted to practice in the province, after spending one year in the office of a member of the association, and passing an examination in design. This office work may be made up of instalments during the summer vacations. The training also prepares the student for the examinations of the Royal Institute of British Architects.

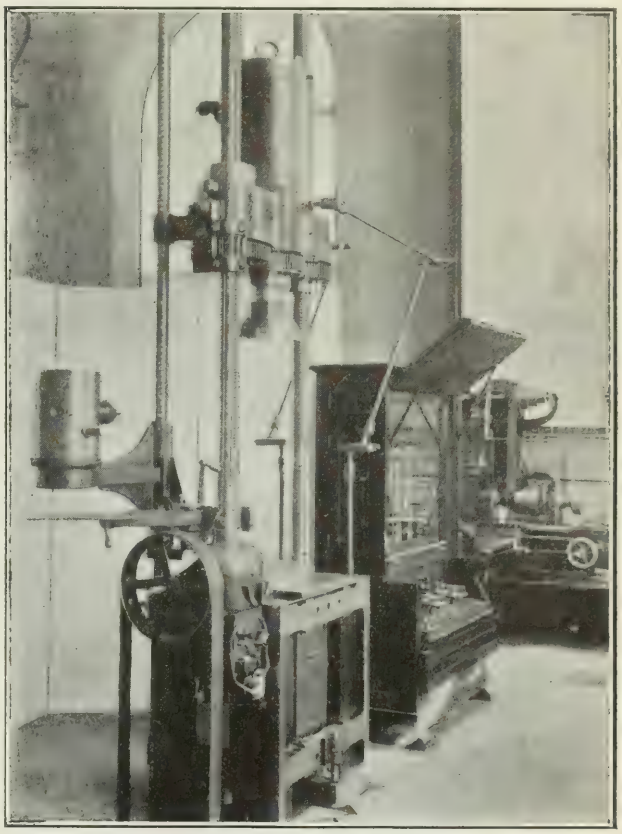
The course is under the direction of the Faculty of Applied Science, but in the first two years general culture courses in history, French, physics and mathematics are taken in the Faculty of Arts. Geometry and English are taken with the first year students in Applied Science and the professional work of the first year includes freehand and architectural drawings, modelling, and the elements of architecture. This work is intended to give the student practice in draftsmanship, and teach him the basic principles of design. Freehand and detail drawings are made of recognized types of forms and architectural details. The student is thus prepared for more specialized professional work of the second year in which design is given a prominent place.

Mathematics and general history are continued in the second year, and the courses in surveying, mapping, and graphical statics of the second year engineering course are included. The architectural work includes lectures and draughting practice in the following: Building construction and details; architectural history; ornament and decoration; modelling; theory of architecture. Continuous practice is given in the draughting room in the development of the principles explained in the lectures, and this is facilitated by the large number of reference books, etc., which are available. The reference library of som 300 selected books adjoins the draughting room, and the equipment of the department also includes some 2,500 large photographs, 5,000 plates and nearly 3,000 selected lantern slides. These are available for reference at all times.

The third and fourth year courses are almost entirely professional. Geometrical drawing and perspective are continued, and the course in engineering law previously referred to is included. Courses are given in graphical statics, structural design and details, hygiene, ventilation and heating, etc., and the architectural work includes theory of design and planning; history of architecture; ornament and decoraton; architectural practice and modelling. The draughting room work includes problems in composition requiring different treatment, and of increasing difficulty. In the latter part of the course a series of planning problems are set, some of which are worked out in detail, and the diploma design for graduation occupies the work of one term.

The summer vacations extend from the end of April to the end of September, but students entering the second year course are required to attend the field work in surveying during the month of September.

Instead of writing an essay, as prescribed for engineering students, students in architecture are required to read and pass an examination on certain books. The prescribed books for the past summer for students entering second year were "The Mistress Art," Reginald Bloomfield, and "Essentials in Architecture," by John Belcher. For third and fourth year students "The Mistress Art" and "Memories of Benvenuto Cellini" were prescribed.



Testing Laboratory. Emory Testing Machine. Capacity 150,000 lbs.

In addition to the above, students must either spend at least five weeks in the employ of an architect or contractor, or submit thirty-five free hand drawings of reasonable size. During the past summer 80 per cent. of the students worked for from three to four months in architects' offices or with contractors, and thus on graduation many will be ready for admission to the Architects' Association of the province.

Summer Employment.—The following information regarding summer employment may be of interest: All students entering the second, third and fourth years are required to state the nature and duration of their summer work. The information is not asked from the first year class, as they have not had any previous connection with the faculty.

The returns for the past summer show that 298 out of 350 students were engaged in summer work. Of these, 13 worked for one month or less; 62 for two months; 18 for 2½ months; 76 for three months; 24 for 3½ months; 78 for four months, and 27 for five months. This gives 85 per cent.

of the students engaged in practical work for an average of 3.2 months each. The varied nature of the work obtained is shown by the following return of the number of students engaged in different classes of work: Mining and geology, 32; surveying, 53; prospecting, 3; draughting and design, 21; machine shops, 48; construction and general contracting, 48; electrical work, 31; metallurgy, 4; chemistry, 7; architecture, 13; office work and railway operating, 30; farming and lumbering, 6; military work, 2.

The programme of the meeting of the Canadian Society of Civil Engineers, in Montreal, from January 24th to 26th, includes a reception by the president and members of council in the Engineering Building, which has been placed at the disposal of the society by the University authorities. The laboratories and workshops will be open for inspection, and no doubt the members of the society will avail themselves of the opportunity of becoming acquainted with the equipment of the faculty, whose work has been described above.

HIGH-HEAD REACTION TURBINES BUILT IN MONTREAL.

The Canadian Society of Civil Engineers will have an opportunity of examining the details of construction of high head reaction turbines during the annual meeting in Montreal. Allis-Chalmers-Bullock, Limited, is the only firm in Canada which builds turbines of this character, and has lately worked out some interesting features. Among the hydraulic turbines now under construction in the shops in Montreal are the following for Price Bros., Limited:

Four turbines in spiral casings, each 4,000 h.p., 225 r.p.m. under 264 feet head for driving pulpwood grinders.

Two turbines in spiral casings, each 3,350 h.p., 600 r.p.m. under 264 feet head, for driving electric generators.

Two turbines in spiral casings, each 600 h.p., 1,000 r.p.m. under 264 feet head, for driving centrifugal pumps, with governors, valves and other auxiliary apparatus.

The accompanying illustrations show many of the details of this style of turbine. The runners are always designed specially to meet the requirements which the conditions call for, and, whenever possible, are made of bronze cast in one

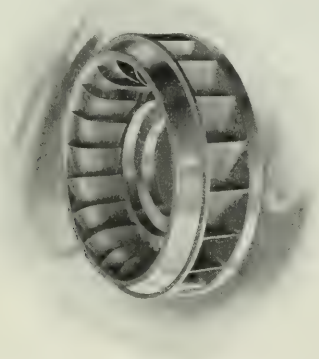


Fig. 1.—Bronze Runner.

piece, as shown in Fig. 1. The runner is bolted to a forged flange or steel hub, (shown in Fig. 2) and only machined steel bolts are used in reamed holes, to make the construction "fool proof" and safe. The guide vanes shown in Fig. 3 are made of forged steel in one piece, are made to gauge, and are interchangeable. Both runners and guide vanes are carefully machined and polished all over and all rotating parts are balanced by static and running methods. Every spiral casing is provided with a "speed ring" (shown in Fig. 4) made of cast steel. This ring is rigid in constructon and

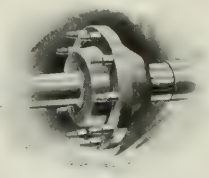

Fig. 2.—Forged Flange.

Fig. 3. Forged Steel Guide Vanes.

is designed to guide the water properly from the casing to the guide vanes and runner.

On all turbines with spiral casing the gate rigging (shown in Fig. 5) is arranged outside, so that it may be attended to without any interruption of operation. All bearings are lined with the highest grade babbitt, and are care-

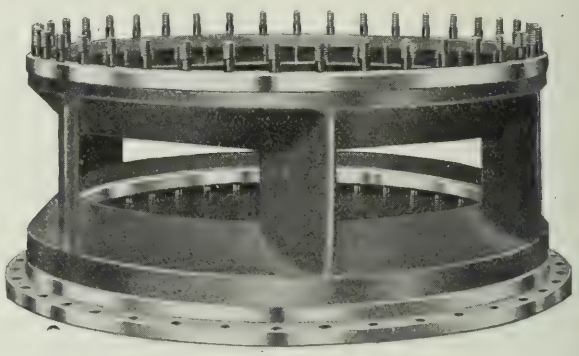

Fig. 4.—Cast Steel Speed Ring.

fully scraped to fit the shaft. The covers for places where water and moving parts come into contact are bronze or steel lined and machined accurately to gauge. Every turbine,

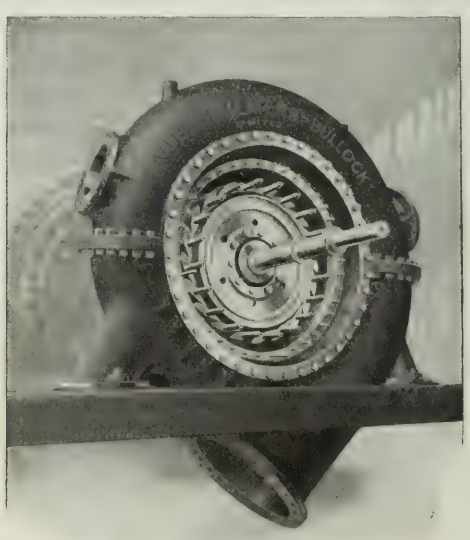

Fig. 7.—Guide Vanes and Runner in Position Within the Casing.

before shipment, is completely assembled in the shop and subjected to an overspeed test, as shown in Fig. 6.

This company has also developed a new oil pressure turbine governor. (Shown in Fig. 5). This governor is pro-

vided with all the modern appliances to make a quick and sensitive regulation possible.

The governor is of the self-contained type, and is designed for any operating conditions. Runaways are not possible with this design. The hand power control is combined with this governor and is ready for connection at any moment, without loss of time. No gears or racks of any kind are used with this governor. The oil pump is of ample capacity and well proportioned to operate without wear and tear. The space occupied for any setting is not more than four feet square. The governor body is of heavy design and neat in appearance. All enclosed parts are easily attended to during operation. The flyball is of the strongest possible design, and its construction is such as to make it one of the most sensitive on the market. The connection of this governor to the turbine is of a very simple construction. The governor is designed in such a way that the turbine gates can be operated either:

1st—By governor operated.
2nd—By hand hydraulically.
3rd—By hand mechanically.

These three operations can be changed at a moment's notice by touching one lever.

There was an impression for many years that it was necessary to go to Europe for high-class hydraulic turbines of this class, but Allis-Chalmers-Bullock, Limited, has shown

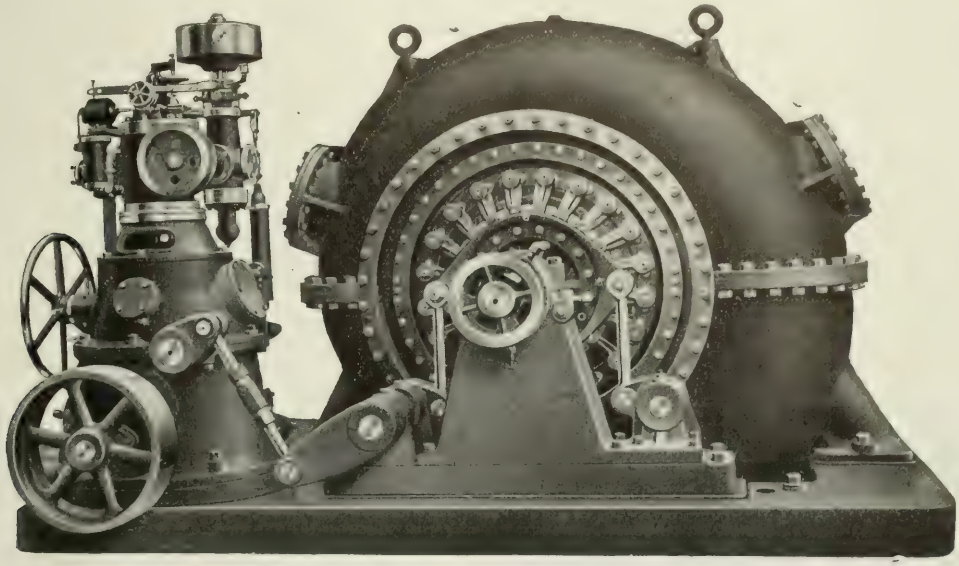

Fig. 5.—New Oil Pressure Governor and Outside Gate Rigging.

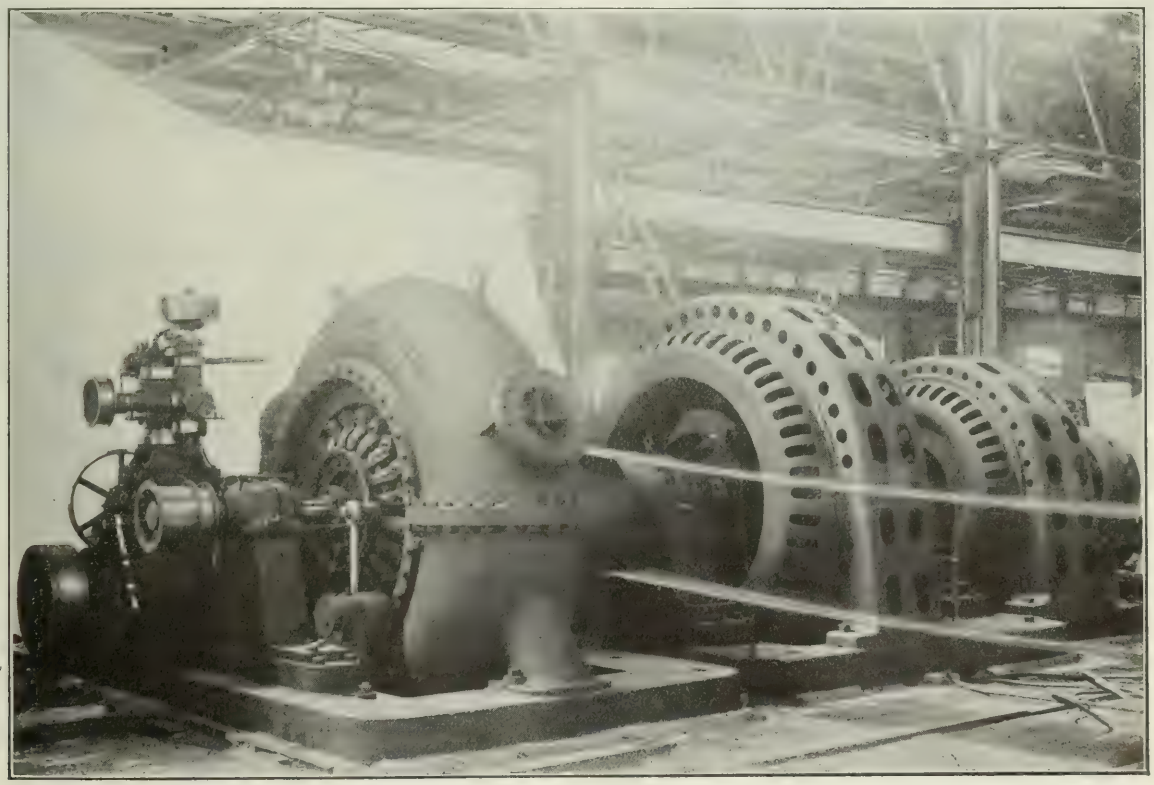

Fig. 6.—1,600 h.p. Turbine Motor Generator Set under Runaway Speed Test in the Shops Before Shipment.

that this is no longer the case. In fact the efficient design and thorough workmanship shown in the turbines which they have built have recently kept in Canada orders which formerly went abroad.

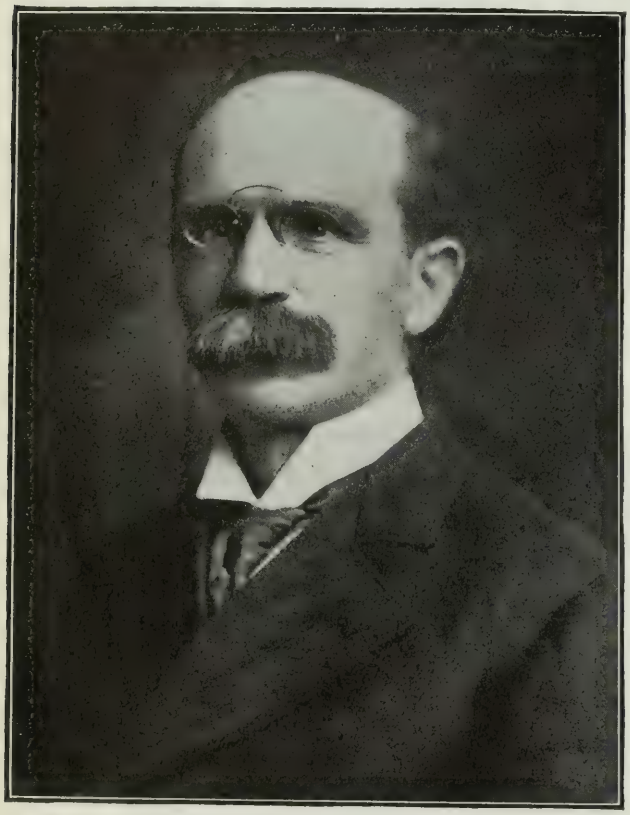
CANADIAN SOCIETY OF CIVIL ENGINEERS.

By E. A. James, B.A.Sc.

This year the Canadian Society of Civil Engineers held their annual meeting in the city of Montreal. Ever since the society was organized Montreal has been the home of the head office.

The objects of the society are to facilitate the acquirement and interchange of professional knowledge among its members and to encourage original investigation.

The term "Civil Engineer," as used in this society, means all who are, or have been, engaged in the designing



MR. C. H. RUST,
City Engineer, Toronto, and President of the Canadian Society of Civil Engineers.

or constructing of railways, canals, harbors, lighthouses, bridges, roads, river improvements or other hydraulic works, sanitary, electrical, mining, mechanical or military works, or in the study and practice of navigation by water or air, or in the directing of the great sources of power in nature for the use and convenience of man.

The society consists of honorary members, members, associate members, juniors, students and associates, and was organized in 1887, having now a membership of over 2,700.

Mr. C. H. McLeod is secretary of the society, and headquarters are situated at 413 Dorchester Street West, Montreal.

During recent years there has been a movement among the members to encourage the establishment of branch societies. It was expected that each branch would have their own society quarters, library, reading room and weekly or monthly meetings. The movement was a popular one and already there are branches at Quebec, Toronto, Manitoba, Vancouver and Ottawa and steps have been taken to organize at least three more branches at other centres.

The forming of branch societies is the natural outgrowth of increased membership, and another evidence of strength and increased membership is the raising of standard of entrance. From year to year the council of the society have been more exacting than the year before and in the amendment submitted this year, still more exacting requirements are being inserted.

The steady upward movement in the qualification for admission does not indicate that the society are unanimous in wishing to make a close corporation, but rather that they recognize the responsibility which they are undertaking when they attempt to give status to members of the engineering profession who identify themselves with the organization.

The present qualification for election to membership is as follows:—

Honorary members shall be distinguished men, eminent in engineering or kindred sciences.

Every candidate for election as member must be at least thirty years of age, and must have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in some school of engineering recognized by the council. The term of twelve years may, at the discretion of the council, be reduced to ten years in the case of a candidate who has graduated in an engineering course. In every case the candidate must have had responsible charge of work for at least five years, and this not merely as a skilled workman, but as an engineer qualified to design and direct engineering works.

Every candidate for election as an associate member must be at least twenty-five years of age, and must have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in some school of engineering recognized by the council. In every case the candidate must have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years.

Every candidate for election as junior must be at least twenty-one years of age, and must have been engaged in some branch of engineering for at least four years. This period may be reduced to one year, at the discretion of the council, if the candidate is a graduate of some school of engineering recognized by the council. He shall not remain in the class of junior after he has attained the age of thirty years.

Every candidate for election as student must be at least seventeen years of age, and must present a certificate of having successfully passed an examination equivalent to the final examination of a high school or the matriculation of an Arts or Science course, and must be pursuing a course of instruction in some school of engineering recognized by the council, in which case he shall not remain in the class of student for more than one year after graduation; or be receiving a practical training in the profession, in which case he shall not remain in the class of student after he has attained the age of twenty-three years.

Every candidate for election as associate shall be one who by his pursuits, scientific acquirements, or practical experience is qualified to co-operate with engineers in the advancement of professional knowledge.

Engineering ethics is a question every engineer has to consider at some time or other. It may be that he debates the subject with himself or he may discuss it with other engineers.

The code of ethics assembled by the Canadian Society of Civil Engineers is a good one, and as the membership

approaches closer to both the spirit and letter of this code, the standing of the society will be improved and its influence increased.

The code of engineering ethics as given in the publications of the society is as follows:—

Every member of the society should perform the work he undertakes to do to the best of his ability and in the true spirit of his engagement, feeling it to be his duty to present all ascertained facts in their true light.

The civil engineer has a right to expect from his client the same consideration and deference to his opinion as is by their clients accorded to the members of other professions—law and medicine, for example—and without which the adviser should decline to advise. The surest way for the engineer to obtain such necessary consideration and deference from the public will be found in his manner of carrying himself.

The assistant engineer must loyally obey and support his chief, to whom it will be his duty to report directly on all matters relating to the work on which they may be jointly engaged. His report should be full and explicit on all important points, and exact to the best of the assistant's knowledge and belief, cloaking nothing, even though going to show that previous reports had been inaccurate or not duly weighed, in some particulars affecting the well being of the business in hand.

The assistant engineer is entitled to look to his chief for, and to receive from him, advice for his guidance in the proper performance of his duties, and, where right, to expect his support in matters in dispute between him (the assistant) and his subordinates, or between him and the contractors working under him. He is also entitled to the aid of the chief engineer's professional experience or counsel where unlooked-for or extraordinary difficulties present themselves, or changes of original plan may be called for in the work on which they are associated, so that responsibility may be fairly apportioned between them.

It is the duty of both chief and assistant, each in his department, to study proper economy in the doing of the work, the management of which they have undertaken, and in every way consistent with the maintaining of the good character of the work to make the client's interest the guiding object.

The engineer may legitimately suggest experiments with a view to improvement, whether in methods of doing the work which he oversees, or for raising its character; but such experiments should only be undertaken with the full consent and co-operation of the person, whether client or contractor, on whom the expense may fall, and on the understanding that to them will accrue all pecuniary benefit from the success of the experiment.

It shall be considered unprofessional for any member of this society to seek the position of an expert to report on any work that is in charge of a recognized engineer.

It shall be the duty of any engineer, before examining any work with a view to report thereon, to give the engineer due notice before going on with the investigation in order that he may have every facility to explain and sustain his methods of carrying on the work in question.

Interchange of professional assistance between members, as tending to promote fraternal intercourse and mutual goodwill, is not to be discouraged, but neither is it to be considered obligatory on a member to respond to the request of a fellow member for professional counsel or assistance. Service so rendered must be entirely voluntary on the part of the member whose aid is sought.

The civil engineer may, consistently with professional status, take out patents for new inventions or for improvements on old ones, and may sell or otherwise dispose of the patents for his own advantage. He may undertake surveys and the engineering of works by contract, or he may take contracts for the construction of works on a percentage of their cost. Advertising with a view to attracting business should, where resorted to, be as far as possible free from egotistic or self-laudatory references, and expressed in language not derogatory to the dignity of the profession.

The civil engineer, whose advice is sought in respect to the usefulness, practicability, and cost of work, should, before expressing his opinion, obtain reliable information on all points involved in the matter submitted to his judgment, including the probable paying capacity of the contemplated undertaking. He must be cautious how he recommends large preliminary outlay, should avoid connecting himself with schemes or projects of merely speculative character, always bearing in mind that his professional reputation will be to a great extent judged by the inherent merits and commercial

COL. H. N. RUTTAN,
City Engineer, Winnipeg, and Immediate Past President of the Canadian Society of Civil Engineers.

value of the undertakings with which his name may come to be associated.

The Canadian Society of Civil Engineers contains among its members leaders in every branch of engineering in Canada. Each year membership in the society is more eagerly sought, and in four years the society should double its membership and quadruple its influence.

NOVA SCOTIA MANGANESE.

Much interest is shown in the new manganese mine at New Ross, Lunenburg, N.S. For upwards of a year, the work of development has been going on, new buildings erected and machinery installed for fitting the ore, which is of a very high grade, for the consumer. In a few weeks the company will be in a position to market the finished product in quantities. In this mine the manganese occurs in fissure in the granite, and in this respect is unique It has been practically proven that the product is eminently suited to the requirements of the glass makers and varnish manufacturers, as apart from its high chemical grade, its physical characteristics give it a long-continued high efficiency.

THE BUILDINGS OF McGILL UNIVERSITY.

By T. W. LUDLOW, B.Sc., M.A., Professor of Architecture, McGill University.

McGill University, like all the older seats of learning on this continent, owes its foundation to a private endowment. The Honorable James McGill, who died in 1813, bequeathed his property of Burnside, consisting of forty-six acres of land, with the dwelling house and other buildings, and a sum of £10,000 in money to found a college, in a provincial university, the erection of which had already been provided for by the British Government. Owing, however, to a disagreement among the trustees, the idea of a provincial university was abandoned; but application was made at once for a Royal Charter for the independent establishment of McGill College, along the lines laid down in the bequest. The charter was granted in 1821, and the Royal Institution for the Advancement of Learning, a body which was incorporated in 1802 to encourage universal education in the province of Quebec, proposed to take possession of the estate. Owing to protracted litigation, this was not surrendered to them until 1829, when the work of teaching was begun in two faculties, Arts and Medicine. The record of the first thirty years of the University's existence is an unbroken tale of financial embarrassment and administrative difficulties, and, with the exception of the Medical Faculty, became almost extinct as a body. In 1852 a revised and less wieldy charter was secured, and in 1855 a new era of progress and prosperity opened.

This second period of the University's history, that is from 1855 to the present day, may properly be called the formative period, as it has been marked by a very rapid growth both in aims and teachings of the institution, an expansion in all branches of learning, the establishment of new faculties (Law in 1853, Applied Science in 1878, and Agriculture in 1907), and the erection of new and modern buildings in which to properly carry on the work of instruction; so that to-day, with fourteen buildings, without counting those of the Agricultural College at Ste. Anne de Bellevue or the affiliated Theological and other schools, brings the University to the dawn of an era of maturity.

The fourteen buildings under discussion are:—

Molson Hall or the Arts Building.....1862
Peter Redpath Museum 1882
Macdonald Physics Building 1893
Redpath Library 1893
Macdonald Chemistry and Mining Building 1898

Molson Hall, or The Arts Building.

Royal Victoria College 1899
Strathcona (Old) Medical Building 1901
Conservatorium of Music 1904
Macdonald Engineering Building (New) and
Workman Engineering Building .....1893 to 1907
McGill or Students' Union 1907
New Medical Building 1911
Observatory.....
Strathcona Hall (Students' Y.M.C.A.).....
Power Station .....

The above buildings divide themselves, architecturally, into three groups, which reflect the prevailing taste at the time when each of the structures was built. These are:—

1. The Greek Revival or Neo-Grecque.
2. Romanesque.
3. The Early Renaissance of Elizabeth's England.

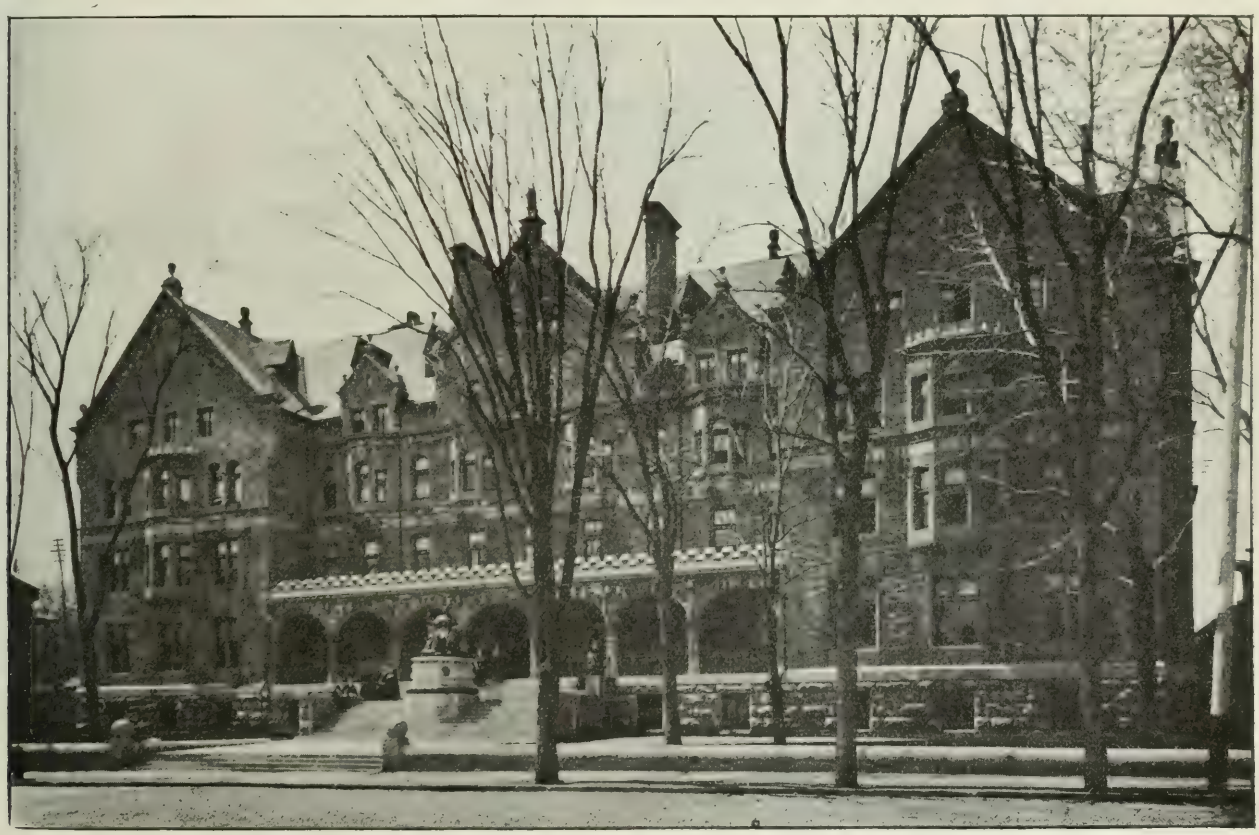
The Greek Revival is a recognized style in the history of architectural development, that owes its origin to the rediscovery of Attic forms by Messrs. Stuart and Revett in the first half of the XVIII. century. The character of the other two groups is based on the modernization of historic forms to suit present day conditions, and they are considered rather in the light of adaptations than styles.

To the first group belong Molson Hall and the Redpath Museum, the two oldest buildings of the University. The older of these, Molson Hall, is, with possibly the exception of the New Medical Building, the finest of all McGill's structures. This Hall is a long, low edifice with a commanding situation on the side of a hill, closing the long vista at the end of the shady driveway from the main entrance to the college grounds on Sherbrooke Street. It consists of a central and two end pavilions of three stories each and connecting wings, joining them two stories in height. The whole is built of local gray stone, which is so admirably suited, from the aesthetic view point, to the low color tones of Montreal's atmosphere. The central pavilion is naturally the focal point of interest; it consists of a very nicely proportioned, cubical building, crowned with a low roof, above which rises a well-arranged lantern. A porch of four Greek Doric columns, supporting the entablature, that does not follow too closely classical traditions and a very low pediment, forms the main entrance to the building. This feature is raised on a high base, and is approached by an imposing ramp of steps, equal in width to the porch itself. The arrangement of the end pavilions and connecting wings shows the same dignified simplicity that marks the central motive, they also show an interesting variety of treatment of window openings, that harmonizes perfectly with the main lines of the composition, yet differ materially one from the other. This is an excellent expression of true symmetry, one where the main masses agree, considered in relation to a central axis line, yet they are sufficiently varied in their individual parts to place this structure in a class above the so-called symmetrical buildings that are characterized by a repetition of parts. Unfortunately, as much cannot be said about the interior.

Directly in front of Molson Hall, situated on a plot of grass at the head of the driveway, is the burial monument of McGill's founder. It was moved to its present suitable location, together with the earthly remains of the Hon. James McGill, from the Protestant Cemetery in 1875. The monument is late Georgian in style and possesses all of the delicacy, charm and quaintness that characterized the funerary architecture of that period.

The second building of this group, the Redpath Museum, was built some twenty years later than Molson Hall, and its style reflects the change of taste even in that short decade. The treatment lacks entirely the vitality of the older structure. Here the front consists of a high central bay flanked on either side by lower wings, in much the same manner as the nave and side aisles of a church. The whole structure is raised on a high base and is approached by a broad flight of steps; above the base the facade is divided into two parts, a low one and a higher one above it. The main entrance is through a doorway in the central bay, above which there are two Corinthianesque columns in antis; this feature is crowned by a pediment. From the decorative point of view this edifice is particularly unfortunate, as the architect was evidently laboring under the impression that all that was necessary to make a good building was to use on a naturally limited surface all of the ornamental forms that he knew, as here one sees, especially on the main front, the whole grammar of classical Greek and Roman motives used indiscriminately, alike as to position, fitness and scale.

The Library, Chemistry and Physics Buildings form the Romanesque group, and they are all the work of Mr. Andrew



Royal Victoria College for Women. Mr. Bruce Price. Architect.

T. Taylor, who for many years was a leading practitioner in Montreal. He may briefly be summarized as a decorative architect, that is, one who designs his buildings around decorative forms, instead of having them grow out of a logical arrangement of parts. This must not be taken in the light of a severe criticism, as Mr. Taylor's work possesses many good points beside a charming decorative arrangement of the exterior.

The Library is the most worthy of this trio of buildings. It, like Mr. Taylor's chief works, is in a style adapted from the rich Romanesque of Southern France, which is known by its picturesque grouping of masses, low circular headed openings, a pleasing arrangement of doors and windows, and interesting decorative details. All of these features are well emphasized in the building under discussion, which has for its focal point a richly proportioned tower on the north front, on either side of which there are two wings, the one to the east containing the main reading room, while the one to the west houses several special reading rooms and the administrative offices. Stretching off to the south, back of the offices and a corner of the general reading room, are the

The Macdonald Engineering Building. View from Southwest.

Prof. P. E. Nobbs, Architect.

stacks. The different functions of the interior are well expressed in the exterior arrangement of this structure, as the long triple windows in the east front of the main reading room and the closely grouped small windows of the stack and offices illustrate.

The decorative details which adorn the exterior are in character with the architectural treatment of the whole. They consist mostly of low relief carvings of vegetable and geometric forms, on the mouldings around the door and window openings, and well sculptured gargoyles at intervals on the cornice.

The interior, reached through a doorway in the tower, has a very nice tone throughout, with the interest chiefly centred on the main reading room. This room is of generous proportions, being 110 feet long, 44 feet wide and 34 feet high, and will easily seat one hundred and fifty readers. The walls are wainscoted in light panelled oak to a height of about eight feet, and an open oak beamed ceiling covers this vast space with pleasing effect. In the east wall there is a group of three long, narrow windows that are filled with good stained glass, in which rich blues predominate. The arrangement of the leading in the other windows shows a carefully studied variety in handling and is well worthy of notice.

The stacks, arranged in four and five stories in the modern seven foot high steel units, have a working capacity of two hundred and fifty thousand volumes, although at present they shelve only about one hundred and thirty thousand books, but the total collection consists of about thirty thousand more pamphlets, maps, and photographs. Of especial interest may be mentioned the Redpath collection of works on English history, and the Griffin library of Canadian history.

Next, in general excellence of design as well as in date, is the Macdonald Physics Building. Mr. Taylor had a much more difficult task here to harmonize the severely technical instruction given within these walls with the picturesque grouping that the style demands, and as is so well exemplified in the Redpath Library. The great laboratories and their adjuncts required for convenience of operation a rectangular building, and the result is an admirably disposed structure on an axis running east and west, with the main front turned towards the south. This building is five stories in height, and is crowned by a well proportioned roof. The ornament is concentrated on the lower and upper stories, in architectural forms, with panels of purely decorative ornament under the windows of the intermediate floors. The architectural ornament on the main floor consists of an elaborate projecting semi-circular porch, which admirably exhibits the characteristics of the Romanesque style. The central portion of the building breaks back above the porch, dividing the facade up into a composition of two end pavilions and a connecting link. This motive of composition is emphasized by a balcony supported on brackets at the level of the upper story, which connects the two pavilions. On the back of the building a similar composition is used, only the connecting balcony is of a different and perhaps more pleasing design.

The interior throughout is simply finished with red brick walls, with plaster or wooden ceilings. The doorways, in many instances, are circular headed and are moulded in terra-cotta with geometric or vegetable patterns, after the Romanesque manner.

There is a finely wrought mantel in the entrance hall with the fitting motto "Prove All Things" cut in its central panel. The delicately carved foliage of the capitals of the supporting shafts and the mouldings of this feature are well worthy of notice, and certainly would excite more attention if the hall were not so small.

The main lecture theatre is up half a flight of stairs from the entrance hall, on the left hand side. It is a fine, high room, finished in light oak and red brick, with a good, heavy flat beamed oak ceiling, and a gallery running across the back and along one side. It will seat at individual chair desks about two hundred persons, and it is fitted with every scientific device for instruction in mathematical physics. The great care exercised to obtain perfect results is shown by the fact that the foundations of the demonstrating desk are carried down to solid rock.

Five years after the completion of the Physics Building and the Redpath Library, the Macdonald Chemistry & Mining Building was opened. This structure is placed between the Physics and Engineering Buildings; thus the group of structures devoted to the use of Applied Science is separated distinctly from the buildings of the other faculties. In style this edifice does not follow the Romanesque form as closely as Mr. Taylor's earlier work, but rather shows a treatment adopted from a later French school, that of the just developed Renaissance, which has more the appearance of being influenced by Spanish, than Italian models.

In this case, as in the one just cited, the structure rises from a rectangular plan to a height of five stories from the main floor, while in the rear, at a considerably lower level, extend shops for the miners and metallurgists to the north and south, making in this way a "T" shaped plan.

Notwithstanding the very ornate entrance motive and the richly moulded cornice at the roof line, this building is

simpler in general treatment than either the Library or Physics Building; the lower story is plainly rusticated and is lighted with arched windows, the intermediate stories are almost severe, with square headed, unornamented openings, while the upper story is somewhat relieved by wall arcades framing the windows. Above the cornice some nicely proportioned ornamental dormers break the sky-line, standing out as they do from a rather low roof. The treatment of the southern face differs from the other sides in that it is divided vertically into a series of bays by buttresses, which terminate under the cornice in inverted scrolls.

The interior contains a lecture theatre, seating about two hundred and fifty students, and several large chemical, assaying, ore dressing and other laboratories. These are all treated more from the utilitarian view point than from one of architectural pretension.

Besides the three buildings already described, Mr. Taylor was the architect of the old Macdonald Engineering Building, which was completely destroyed by fire on April 5th, 1907, the Thomas Workman Mechanical Engineering Building, and the old Strathcona Medical Building, which was partly destroyed by fire on April 16th, 1907.

The remaining buildings of this group show a complete change of style from his other work, being severely plain in their treatment, depending upon an exceedingly well proportioned fenistration rather than decorated mouldings and panels for their chief effect. Looking casually at the old Medical Building, this effect is somewhat lost owing to the wretched colored yellow paint that has been used on the mullions, transom bars and window frames.

After the fire of 1907 two stories were added to the Workman Building. These are easily distinguished from the older work, because they are in dressed stone, which forms a pleasing contrast with the rougher stone work below. More will be said about this later.

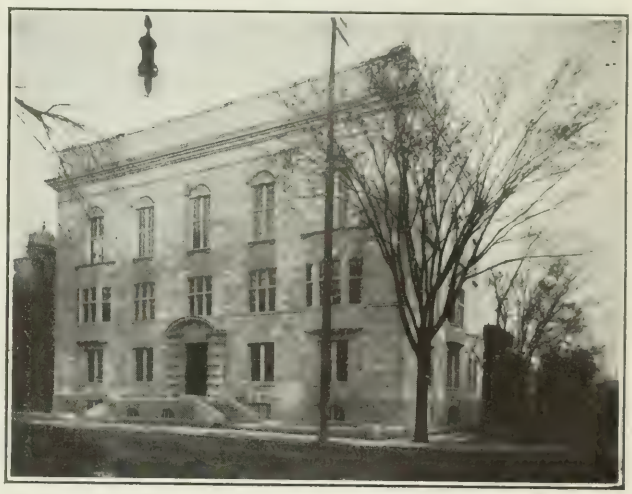
The third group, comprising those structures built in the style of the Early English Renaissance, includes such buildings as the Royal Victoria College, the new Macdonald Engineering Building, the McGill Union and the new Medical Building. These are unquestionably the finest of the McGill edifices, and they show what systematized study has done for the development of modern architecture; built under diverse conditions by men who received their training either in the Old Country or in the larger centres of the eastern States, they show a remarkable homogeneity in style and fitness to their surroundings.

The oldest of these, the Royal Victoria College, the academical and residential hall for McGill's women students, was made possible through the generosity of Lord Strathcona and Mount Royal. This building, opened in September, 1899, was erected from the designs of the late Mr. Bruce Price, formerly a well known architect of New York. Mr. Price is familiar to all Canadians because of his very excellent work in designing the Place Viger Hotel and Terminal Montreal and the still finer Chateau Frontenac at Quebec.

This structure, situated on Sherbrooke Street at the head Union Avenue, just east of the main college campus, has commanding situation that shows the fine design off to the best advantage. The composition consists of two end pavilons joined by a connecting link, which is subordinated the pavilions only by the fine seven-bayed arcade, which rves at the same time as a porch and the joining link. The uilding rises to a height of four stories and an attic, above low basement, and is approached by a broad ramp of stairs qual in width to the three central bays of the arcade. In e centre of this ramp there is a fine pedestal with bronze rnamentations, which is surmounted by a graceful and well esigned seated bronze statue of Queen Victoria.

Each of the end pavilions terminates in a gable, which marks the height of the ridge of the roof of the main building, the eaves line of which is broken up by one major and two minor gables, of similar proportions but smaller than those of the pavilions. Oriel windows, extending through two stories in the pavilions and one story in the body of the building (the connecting link) form the chief decorative note outside of the arcade, on this facade, which depends upon subtile proportions rather than ornamentation for its chief effect. The roof is broken up in an interesting manner by a series of small dormer windows and chimney stacks.

The treatment of the interior is very simple, but the deposition of parts is convenient and good. On the entrance floor there are the offices of administration, lecture rooms, students' common room and a spacious dining room in a separate wing projecting to the north; on the floor above there are more lecture rooms, a library and reading room and the largest assembly hall in the University, in the wing over the dining room; while the two upper floors are devoted entirely to suites of rooms for the resident students and tutors. A well equipped gymnasium service and kitchens



The McGill Union, Sherbrooke Street Front.
Prof. P. E. Nobbs, Architect.

are on the basement. The whole building is well but not luxuriously furnished, and has a comfortable, homelike appearance that is alike beneficial for the student and the visitor.

The new Macdonald Engineering Building, built to replace the former structure which was destroyed by fire in 1907, rises from the old foundations. This handicapped the architect, Professor Percy E. Nobbs of the Architectural Department, now practising under the firm name of Nobbs & Hyde, architects, at the very outset of his task, and made the final solution all the more creditable to him. The main lines of the composition follow those of the Royal Victoria College, that is, the building is composed of two end pavilions and a connecting link, but at this point the comparison must stop, as every line and window of the Engineering Building reflects the serious character of the work carried on within it. This structure rises from a high rusticated base, above which there are four stories in the pavilions and three in the connecting link. The roof is moderately high and is broken up by small dormer windows and some large chimneys at the ridge.

The entrance motive consists of a projecting vestibule, the chief features of which are the flanking rusticated pilasters and a broken curved pediment, above which rises a simple carved group symbolizing engineering. In direct elevation this entrance feature harmonizes very well with the

composition, but from the side the effect is somewhat spoiled by a too great projection. Nicely curved steps lead up to the doorway from either side.

This central decorative note is repeated on the next story in two sculptured panels bearing the arms of McGill, and on the story above by a small balcony carried on fine brackets decorated in low relief carving. At the third story level a second balcony runs across the facade connecting the pavil-

McGill Union, Students' Lounge on Second Floor.
Prof. P. E. Nobbs, Architect

ions; this is interrupted in the centre by an edicule framing a small window and a niche, which runs up and breaks the line of the main cornice.

The ends and the back repeat the treatment of the main front, as far as it is possible to do so, and at the same time join on to the Workman Mechanical Building.

The two upper stories of the Workman Building—the lower one consisting of a high arched motive surmounted by a story with small rectangular openings—is also the work of Professor Nobbs, with its most charming feature to be seen in the far projecting concrete cornice.

The Engineering Building was erected as the permanent home of the Department of Civil Engineering, Architecture and Transportation, but until other structures can be erected the Departments of Electrical and Mechanical Engineering are given here temporary accommodation. The space is allotted as follows:—The great laboratories for the Civil, Electrical and Mechanical Engineers are in the basement and have a clear height of twenty-three feet, which gives ample room for the most interesting experiments. The first floor is devoted chiefly to the Agricultural Museum, the Museum of the Railroad Department, the Engineering Reference Library, and locker space. On the floor above are the architectural draughting and lecture rooms and reference library, the private offices of the professors and the faculty room; while the two upper floors are given over to large draughting rooms and lecture halls.

No special interior architectural effect has been sought after in this building, the dominant note being security against fire, as each of the floors is divided into sections by unplastered brick fire walls, with great copper fire doors operating automatically with a fusible link to isolate any conflagration that might start.

The halls, lecture and draughting rooms and museums are finished in a lovely rich buff yellow brick, laid up in various bonds. In some cases the brickwork is four-foot wainscot only, in others it goes up to the ceiling; when the wainscot is used, the walls above are plastered and tinted an agreeable shade in a low key. The central portion of the second floor, used for administrative purposes, is more decorative than the rest of the rooms: here the corridor is wainscoted with mat glazed white terra cotta tiles, with at intervals decorative panels in terra cotta, symbolical of the different departmental activities. In the faculty room there is a fine but simple moulded ceiling, with a great elliptical panel in the centre, framed with a rich band of fruits and flowers in low relief. The walls are tinted a delicate green, and the hangings are a dull orange buff. The finish of the furniture blends in color with the hangings, giving to the whole room a warm and attractive aspect.

The furniture throughout the building was also designed by Professor Nobbs; it is particularly interesting on account of its variety, the excellence of the substantial designs, the fine workmanship and beauty of finish.

The most beautiful of Professor Nobbs' buildings is the McGill Union, situated just off the college campus on the corner of Sherbrooke and Victoria Streets. It is a rectangular structure 91 feet long by 71 feet deep, and rises in three well proportioned stories above a low basement. The upper story is terminated by a nicely moulded cornice, which is crowned with a high plain attic. The chief decorative features of the main front are the entrance and two oriel windows on the second story at either end of the composition. The doorway consists of a pleasing shallow porch, formed by a group of three rusticated pilasters, crowned by a curved pediment, in the tympanum of which there is a shield bearing the arms of McGill. In the centre of the Victoria Street elevation there is, also on the second story level, an oriel window which is flanked by two slightly projecting decorative chimneys which break through the cornice in a pleasing manner. The windows of the upper story are considerably higher than those of the stories below, and thus fittingly express on the exterior the great hall within.

New Medical Building. Front Elevation from Upper Campus.
Brown & Vallance, Architects.

The arrangement of the interior, which is given over entirely to social intercourse between the students of all faculties, is very simple, but well laid out; it is further a splendid expression of the proper handling of different colored materials to obtain a rich and harmonious effect. On the entrance floor, beside a commodious hall, there are the dining and grille rooms; on the second floor there is a splendid lounging gallery, running across the whole front of the building, 88 feet long by 21 feet wide, back of which are billiard, news and reading rooms, a library and a study. The top floor is given over to the great hall in front—a room 88 feet long by 45 feet wide—and several small rooms for society meetings. The interior is too rich and varied to be properly described within these limits, but particular attention must

be called to the delicate moulded plaster work of the ceilings and cornices, the grace and variety of the wrought iron details, the interesting heraldic devices, the fine joining of the panelling and furniture, and the varied and harmonious color scheme of the whole.

The last of the English Renaissance group forms the latest addition to McGill's equipment. This is the New Medical Building which was completed only last spring from the designs of Messrs. Brown & Vallance, architects, Montreal. This structure is without question the finest building of the University and one of the finest in the whole Dominion, the great pity being that its situation at the corner of University Street and Pine Avenue, although excellent on account of its proximity to the Royal Victoria Hospital, is unfortunate from the view point of the observer, as besides being somewhat screened, the sharp rise in the ground from the Milton Street level to the building makes it very difficult to see more than a portion of the composition at any one time.

New Medical Building. Rear Elevation from Royal Victoria Hospital, Showing North Wings.
Brown & Vallance, Architects.

In plan this building is of the conventional "E" type with the three wings projecting to the north. The body of the building to the south recalls the northern divisions in the main masses, and joins them by recessed stair towers, which are built out from the lower story, to form the entrances. The central portion is given over to the library and stack, the reading room being on the top floor, while the other two floors above the basement are devoted to the storage of books and supplies, and for administrative purposes. The east and west wings, to the south, are occupied by smaller departmental laboratories and lecture rooms; while large laboratories, the museum and an assembly hall fill the northern wings.

The interior disposition is exceedingly well expressed in the arrangement of the outside, the library, for instance, with its three oriel windows; the stack below by slit openings, while the great laboratories and halls are shown by large finely proportioned windows.

The interior is treated with the same simple harmony that characterizes the exterior, and is so designed that the first impression is one of spaciousness and light. The halls, corridors and many of the rooms are finished with a mat white terra cotta wainscot, the dead whiteness of which is relieved by shields bearing the names of famous men of medicine in red or gold letters, or colored heraldic devices.

The Museum, three stories in height, occupies the central northern wing. It is a cross in plan, with a low glass dome over the central rotunda. The faculty room on the ground floor with its fine mantel, and the reading room on the top floor, show the refinement and simplicity to which this style lends itself.

Of the other buildings Strathcona Hall, the home of the University Young Men's Christian Association, on Sherbroke Street, just opposite the college gate, and the new power station, back of the Arts Building, are the most interesting. Strathcona Hall was built from the designs of Messrs. Finley & Spence, architects, of Montreal. It is a rectangular building of the modified French type, five stories in height. The two lower floors are given over to social purposes, while the upper ones afford residential accommodation for about sixty students. The interior is nicely finished, but is not as rich or varied as the interior of the Union.

The Power Station, the work of Professors Nobbs and Durley, has a splendid equipment, which includes boilers of 1,000 h.p. and engines and generators of 600 kilowatt capacity. The heating distribution is partly by tunnel and partly by underground conduit, and is utilized in the New and Old Medical, Engineering and Workman, Chemistry & Mining, and Physics Buildings. The electric current for light and power is distributed through cables in vitrified clay conduits to all of the above structures as well as to the Royal Victoria College, the Union and Strathcona Hall.

In conclusion, the general impression left on the mind by the McGill group is one of homogeneity and repose. The diverse styles of the individual units is lost in the spaciousness of the campus, which at the same time separates yet binds the buildings together. Out of this whole, two buildings stand forth prominently, Molson Hall and the New Medical Building, the older one dominating the lower campus, the newer one the upper campus. Two other buildings also claim attention, the Union and the Royal Victoria College, but on account of their isolation they lose in comparison with the main group.

A NOVEL METHOD OF POURING CONCRETE BRIDGE FLOORS.

In the construction of the main viaduct of the McAdoo Tunnel extension into Newark, a very interesting method was used in pouring concrete bridge floors, which are trough-shaped and each 13 ft. wide, 11½ in. thick, and laid in sections 250 ft. long with expansion joints between.

The forms are built complete several hundred feet in advance of the concrete, and the reinforcing steel is set and tied by the force of the steel contractor before a run of concrete is started. Concrete is then placed by two traveling plants on the deck of the viaduct. One consists of a 7-ft gauge car carrying a 1-yd. Ransome mixer and timber feeding bins.

It runs on the temporary track mentioned at one side of the slab which is being placed. This track has three rails to accommodate standard-gauge and the 7-ft. gauge. A locomotive crane on the track accompanies the traveling plant and supplies its bins from material cars standing on one side of the outer freight tracks below. Concrete is delivered from the mixer to any part of the slab on the opposite half of the viaduct by a sectional chute, and is tamped in place by the concrete gang. Under this plan of operation 250 ft. of single track slab is placed in an 8-hour day and at times two sections, or 500 ft., have been laid, the time required being 14 hours. On a part of the work, in placing the second track-slab, a second mixing plant has been installed, consisting of a mixer on a flat car, with the material cars coupled at the ends. This traveling plant moves over the completed first track and operates similarly to the other described.

THE GREAT NATIONAL PORT OF CANADA.

Features of the Important Extension Works in Progress in Montreal Harbor.

By FREDERICK W. COWIE, Chief Engineer for the Montreal Harbor Commissioners.

The first attempt to make a harbor for ocean vessels at Montreal was in 1830.

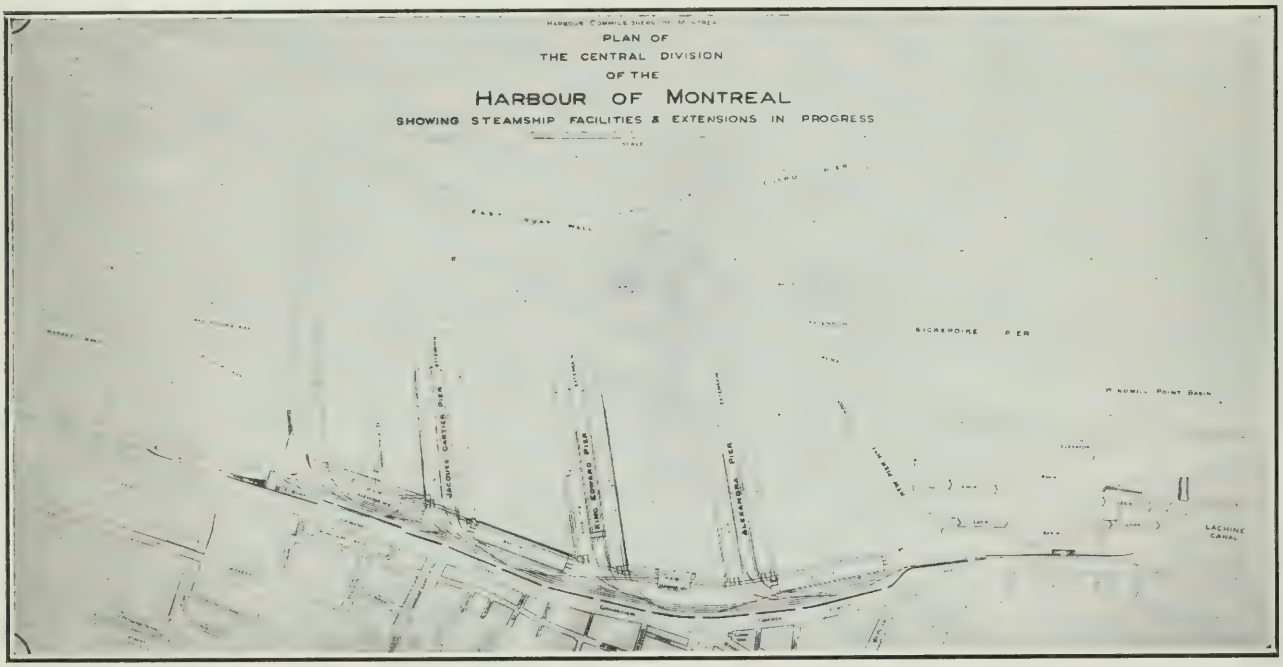
The Canadian inland canal system, connecting the Great Lakes of the central part of the North American continent with the St. Lawrence at Montreal, had just been opened. The physical features of the locality, the trade situation, and the position as a point of interchange between ocean and inland vessels was recognized.

The city of Montreal was fast becoming a commercial and manufacturing centre, and the situation for warehouses and trade was excellent.

From 10 feet in 1850, the channel had been deepened in 1888 to 27½ feet at ordinary low water, over a length of river requiring dredging of about 50 miles, the work being carried on departmentally by the Harbor Commissioners of Montreal.

In 1888 the Government of Canada, recognizing the St. Lawrence as the national route of Canada, assumed the debt incurred with respect to the channel and opened the waterway free to the shipping of the world.

The government, in 1899, undertook the task of deepening the channel about four feet to obtain a depth of 30 feet



Plan of Central Division, Montreal Harbor.

Eastward was the mighty St. Lawrence, with its clean water and permanent river bed, passing through Lake St. Peter and on 160 miles to Quebec, and 800 miles farther to the Atlantic Ocean.

Navigation to Quebec was an accomplished fact for all classes of ocean vessels, but at Lake St. Peter, half way up to Montreal, there was only a depth of 10 feet at low water.

The River St. Lawrence Ship Channel.—Commencing modestly, as it would be considered at the present time, but on right lines, the Montreal far-seeing business men undertook to construct a harbor and to deepen the channel through Lake St. Peter.

Their lessons were gained from the successes in taking navigation up the Clyde, which, before being improved, had been a shallow stream, but with the deepening of the river had resulted in creating the port of Glasgow.

Dredging on the St. Lawrence commenced in 1850. The plant was designed and the machinery made in Scotland.

of the lowest stage of river level recorded, and of widening, straightening and marking the channel with the most modern system of aids to navigation.

In 1907 the channel was opened to commerce with a depth of 30 feet, the actual lowest recorded depth that season being 31 feet 10 inches, and having a magnificent system of lights, buoys, signal service and swept channel.

The standard curves are easy and the width ample, as compared with any other artificial navigable waterway of the world.

Montreal harbor and the St. Lawrence has had a bad name. It is unfortunate that in Canada misfortunes are often unduly advertised. The facts and actual records show to the contrary, and the St. Lawrence should be known as the most advantageous route in the world.

The St. Lawrence, as well as the whole of the Great Lakes navigation, amounting to 70,000,000 tons per annum, is closed by ice from December to April of each year. This situation is accepted for the present, but the future may

bring about great changes, both on the Lakes and the St. Lawrence.

During the navigation season the St. Lawrence has splendid weather conditions, and is notably adapted to navigation. Fogs are very rare in the whole of the contracted part of the river between Murray Bay, 235 miles below Montreal, right up to the harbor.

In 30 years only two ships have been totally lost between Quebec and Montreal.

Groundings, which are so well advertised, are not frequent. The reports of 1906 state that between Montreal and Quebec the loss due to navigation accidents did not amount to $1,000. During the season just closed only one marine accident of any importance happened in the ship channel, when a large freight ship grounded a short distance below Montreal and was released by tugs after lightering part of the cargo. None of the accidents whatever in recent years have been due in any measure to the channel.

Montreal Harbor.—In the consideration of Montreal as a position for a great port, except for its winter season, it would be regarded as an ideal situation, according to the best British and Continental practice.

1. It is as far inland as it is possible for ocean navigation to go.

2. It has a splendid channel approach and dredging plant organization at least equal to any in the world.

3. The navigable conditions are excellent.

4. It is on the direct lines of the great summer trade route of North America.

5. It is the nearest and most advantageous ocean port for a large section of the North American Continent's most productive area.

6. It is a route which, with its up to the present meagre facilities, has successfully held its own with the Buffalo-New York route.

7. It is the eastern terminus of the St. Lawrence Canal System, giving 14 feet navigation, from Montreal to Port Colborne.

From Port Colborne the depth is 20 feet to Buffalo, Cleveland, Detroit, Chicago, Sault Ste. Marie, Fort William and Duluth, a total distance of 1,400 miles.

8. Montreal is the railway centre of Canada, trunk lines extend in every direction and three transcontinental lines first reach ocean navigation at Montreal.

9. Physically, Montreal is favorable for the construction of a port.

10. The water is free from sediment and constant dredging is not required.

11. The whole of the water front and river bed is controlled by the port authorities.

12. The harbor is in the heart of the business section of the city.

13. The railway connections with the docks are the best on the continent.

14. The great transportation companies of Canada, both rail and water, have their headquarters in Montreal.

15. The trade by the St. Lawrence to and from Montreal is now 25 per cent. of the total foreign commerce of Canada.

The total length of wharfage is 38,097 feet, or 7.215 miles.

The total shed area is 35 acres.

There are no tonnage dues on vessels.

The revenues are chiefly derived from wharfage rates on the goods, rentals of sheds and space, storage and handling of grain and operation of harbor railway terminals.

Payment of pilotage to the port is compulsory, and it is controlled by the Government of Canada.

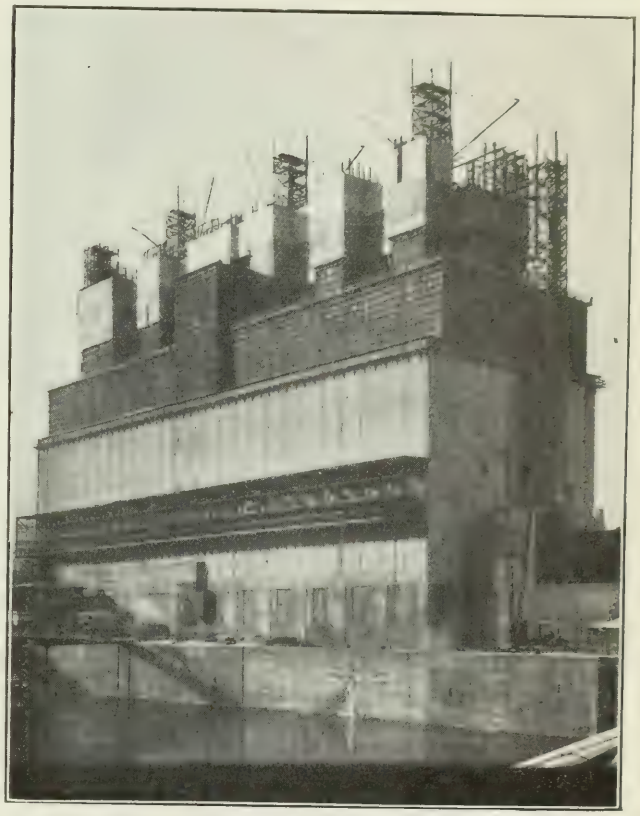
Physical Description of Montreal Harbor.—The jurisdiction of the harbor commissioners extends over the whole of the River St. Lawrence, with the exception of the ship channel, from Bout de l'Ile to above Victoria Bridge, a distance of 17 miles. This area comprises all the land under water and the beaches up to high water mark, including the whole of Ile Ronde. Thus the whole of the water front on both sides of the river is under the jurisdiction of the commissioners, who hold it in trust and administer it for the Government of Canada.

The total water area is 12,000 acres.

The total land area, improved, is 200 acres.

The present harbor represents a development of 80 years.

There is no rise and fall of tide, but the river level fluctuates to an extent of about 12 feet from high water in the spring to low water in the autumn. During the winter, due to ice shoves, the water occasionally rises to an extreme of 28 feet above the low water level.



Elevator No. 2 Under Construction for Harbor Commissioners of Montreal.

An artificial embankment, parallel to the shore, about one and one-third miles long, protects the whole of the upper part of the harbor, including the entrance to the Lachine canal, from not only the currents of the river, but from ice shoves. This constitutes the protected tidal basin in which the water rises and falls with the river level.

It has not been necessary to purchase any land above the high water mark on the beach, as all piers and wharves have been made artificially by building out into the shallow water, and the berths formed by dredging.

The Storage and Handling of Grain.—Montreal harbor being the farthest inland ocean port on the Northern Continent, and also the terminus of the inland Canadian canal

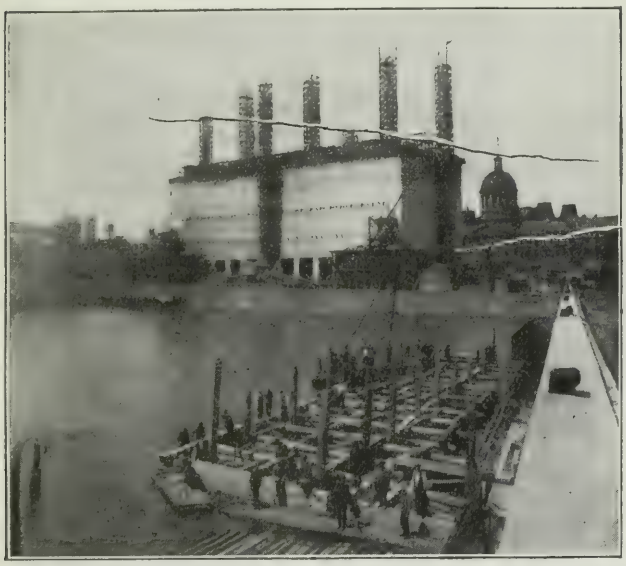
and railway routes, it is an important factor in the grain-carrying trade of the northern part of the continent.

A few years ago the bulk of Western grain came to Montreal in barges. These vessels, without machinery and with small crews, could afford to hold grain in storage until the ocean ship was ready for it, and the grain was then transferred from the barges to the ships by floating elevators.

With the enlargement of the canals, much of the grain now comes to Montreal in steamers capable of carrying about 2,500 tons on the present 14-ft. draft of the Welland and St. Lawrence canals. These vessels cannot afford to wait, but must unload their cargo at once, otherwise they will not choose this port.

Grain coming from Georgian Bay ports by rail must also be unloaded quickly, as even now, during the grain rush, there is a constant railway car shortage.

In the last few years, therefore, the storage and handling of grain has become a new problem in harbor economy. In order to solve it, the harbor commissioners in 1903 erected a modern storage elevator, having a capacity of 1,000,000



Victoria Pier, Showing Construction of Cribwork Substructure New Finished Concrete Quay Wall.

bushels. The G.T.R. leased a site from the harbor commissioners and also erected an elevator, in 1904, having a capacity of 1,000,000 bushels. Other elevators having a capacity of 2,100,000 bushels have been principally occupied with local business.

Elevator No. 2.—Additional storage capacity being urgently required, the construction of Elevator No. 2 was commenced in 1910. The site chosen was on the bulkhead wharf, opposite Jacques Cartier Square, between Jacques Cartier and Victoria Piers. Although planned in 1909 to have a capacity of 1,000,000 bushels, the designs were made in 1910, by order of the commissioners, for a capacity of 1,750,000 bushels, and the elevator was commenced. The grain congestion in 1911, being even more acute than in 1910, the commissioners decided in July, 1911, to enlarge the storage capacity of the elevator under construction to the total of 2,600,000 bushels.

The unique feature with regard to the handling of grain in Montreal harbor is the placing of the elevators in such positions that by a system of conveyors the grain can be carried direct to the ships at their different berths and delivered without interfering with their ordinary loading and unloading.

The construction of the marine tower jetty, the new quay wall in front of the elevator, the excavation for the site and the railway tracks were undertaken directly by the harbor commissioners' engineering department.

The elevator designs and construction were given to the John S. Metcalf Co., Ltd., as designing and constructing engineers for the commissioners.

The illustration showing Elevator No. 2 gives an idea of this immense structure and its progress towards completion.

It is not claimed to be the largest elevator in the world, but it will be the most completely equipped and connected with the most extensive conveyor system ever put into operation.

The elevator, while designed primarily for car business, will have two unloading berths for vessels and, with a receiving capacity of 250 cars of grain per 10 hours with an equal quantity by vessel, it should take a foremost place in the Canadian equipment for the storage and handling of grain.

The new elevator is built of reinforced concrete throughout. It is a structure 456 ft. long by 100 ft wide. The receiving elevator is 314 ft. long by 100 ft. wide. The bins have been completed and the frame work of the cupola has been carried up almost to the top. The portion of the elevator, 142 ft. long by 100 ft. wide, which will be used for storage purposes only, has not yet risen above the surface of the ground; the driving of concrete piles for this portion being now in progress.

The working elevator is built on wooden piles cut off at low water level, which is about 25 ft. below the top of the wharf. In order to get the elevator pits to the necessary depth, a deep basement is required and for that reason the excavation is carried down to low water mark and wooden piles driven. For the storage addition, where no basement is required, concrete piles with their tops 17 ft. above low water level are used.

The wooden piles beneath the working elevator are covered with reinforced concrete slab 3 ft. thick. On top of this the piers and walls of the foundation are built up to approximately track level. The first story consists of large reinforced columns and girders supporting bins. The bin walls are of reinforced concrete 90 ft. high with walls 8 in. thick. Total number of bins in the building is 205. The bin bottoms are of reinforced concrete of a design originated especially for this elevator, which affords a large amount of head room in the first story. On top of the bins the cupola is built. This consists of reinforced concrete column and girder work, with floors, roofs and curtain walls of concrete. The top of the bins is 113 ft. above track level, and the cupola is 107 ft. high above the top of the bins, making the total height of the building 220 ft. This elevator is, therefore, one of the very highest reinforced concrete buildings ever constructed in any country, about as high as a 16-story office building.

In the construction of the bin walls of the elevator moving forms were used. They were raised by means of 1¼ in. threaded steel rods imbedded in the concrete, on which a special nut carriage is used. This nut carriage is turned by means of steel bars and as it climbed the rods the forms moved upward with it. The bins were constructed in two units. Progress on the first unit being at the rate of about 4½ ft. per day, and on the second unit of over 6 ft. per day.

The new elevator marine towers and galleries will be operated by electric motors, as are the present elevator and galleries. The new motor equipment will total about 5,500 horse-power, and a very efficient and complete system of telephones and electric signals between the shipping gallery and

elevator and between various parts of the elevator will be installed.

High Level Railway Tracks.—The railway tracks on the wharves were formerly all located on what is commonly termed low level wharves. This level is above the level of floods during navigation season, but during the winter and spring floods is always submerged. In 1898 the wharves in the central part of the harbor were raised to high level, that is, 24 feet above the low water. These high level wharves have only been submerged on two or three occasions during record spring floods.

The high level wharves, up to the year 1910, were only included in the central part of the harbor, and between Victoria Pier and the eastern limit of the harbor railways that were constructed at low level and, therefore, not only put out of business in winter, but required a great deal of work for repairs and removal of ice in spring in order to prepare them for traffic.

In 1910 the harbor commissioners authorized the construction of high level railways from Victoria Pier eastward, for the purpose of facilitating traffic all year round and for the abolition of level railway crossings.

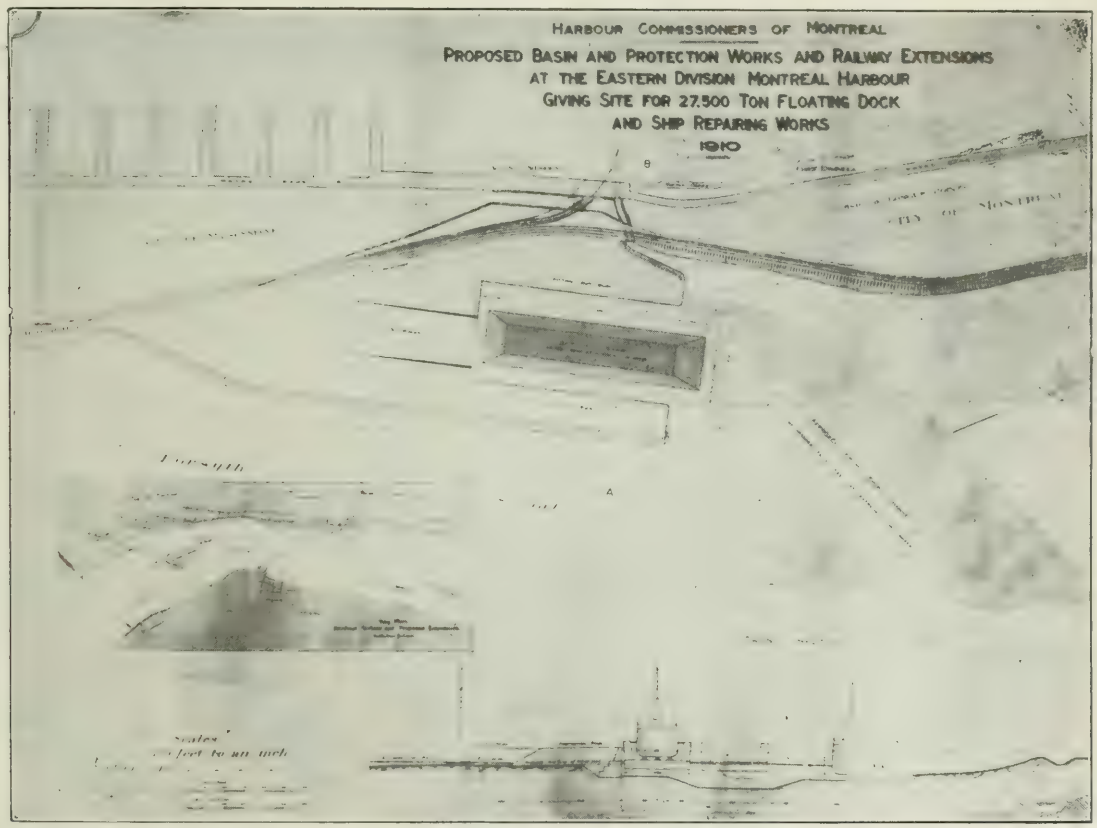
The method of raising the level consisted in the construction of an earthwork embankment, the track being elevated to an extent of about 14 ft. to a level which would be above extreme spring floods.

At 11 of the most important connections with city streets subways were constructed with permanent concrete abutments and steel bridges. At the two important city approaches, opposite Bonsecours market and Berri Street, opposite the subways leading to the harbor, switching railways on the low level were completely abolished and the wharves permanently paved. This now permits the large number of passengers and carriages appoaching to or coming from river steamers to pass without danger from the greatly increased railway traffic along that important railway thoroughfare. At the Longueuil Ferry, another important passenger landing, the low level railway track was also removed and another safe and convenient access between the ferry steamers and the city streets provided.

The construction of this high level railway embankment was commenced in 1910, and was fully completed during the past season. In the construction of this embankment about 650,000 cubic yards of material were used.

Twelve miles of new railway track were laid, eleven steel bridges were constructed, and 520 tons of rock ballast were used.

The harbor railways, which are operated directly by the harbor commissioners' traffic department, now extend from the foot of the Lachine Canal eastward to Racine Pier, along a water front of 5½ miles. Railway connections are given to the G.T.R., the C.P.R., the C.N.R., and the Montreal Locomotive Works.



HARBOUR COMMISSIONERS OF MONTREAL
PROPOSED BASIN AND PROTECTION WORKS AND RAILWAY EXTENSIONS
AT THE EASTERN DIVISION MONTREAL HARBOUR
GIVING SITE FOR 27,500 TON FLOATING DOCK
AND SHIP REPAIRING WORKS
1910

General Plan, Dry Dock Site.

Victoria Pier and Market Basin.—In the scheme of extensions, designed in 1909, every consideration was given to enlarging the steamship accommodation in the central part of the harbor, to connect with the present shed system and the successful grain equipment already in operation and proposed for this season.

At the same time, it was recognized that river and passenger and market vessels should have a location convenient to the city transportation systems and the Bonsecours market.

The improvement of the old Victoria Pier was proposed on the same lines as the old pier, except that the upper and outside quays should be high level for steamships, and the whole of the inner basin quays low level, fitted with slips and exclusively devoted to vessels of the river class.

As most urgent, this was one of the first items of work commenced in 1910. It involves construction in the most congested part of the harbor, while passenger and general market and shipping business is being carried on.

The high level steamship portion will give berths for five ocean vessels, where permanent sheds, railway and grain shipping facilities will be available. The completion of it will involve the widening of the ship channel to 700 feet, the diversion of the guard pier to give the necessary room and protection and compensation by enlarging the channel for the outlet of a portion of the flow of the river, south of St. Helen's Island.

Construction Work, Dry Dock Basin.

The present three piers, which are too short, may then be lengthened according to the plan of extensions.

The market basin, designed for river vessels, will provide 4,000 feet of quays, or 20 berths, averaging 200 feet each. This wharf is all to be constructed at low level, with slips in the concrete quay walls for the convenience of this class of vessels, most of which load and discharge by gangways.

At the close of the season of 1911, 600 ft. of high level quay wall had been completed, and 300 feet advanced sufficiently so as to be capable of completion in May, 1912.

The contract was let for the construction of the first permanent transit shed, which was designed to be similar to the 14 two-story fireproof sheds already erected. By the close of the present year foundations will have been completed for this shed and erection of the steel work commenced, and it is hoped that this first permanent berth in connection with the present scheme of extensions may be sufficiently advanced to be occupied early next season.

The special engineering features in connection with this large work of construction are the wooden cribwork founded 37 feet below low water level, and strong enough to carry a solid concrete wall 24 feet high from low water level to cope; the filling of the interior of the wharves and the putting in of a system of reinforced concrete piling through the newly filled ground to hard bottom, for permanent sheds; and the means taken to make the concrete walls, when constructed in water, able to withstand the disintegrating action of weather and frost.

Dry Dock Site.—One of the most important items of construction work in connection with the progress of the harbor improvements is the important work of providing a site for a floating dock in the eastern division, below St. Mary's Current.

A glance at the chart will show, at the boundary line between the town of Maisonneuve and the parish of Longue Pointe, near the outlet of Molson's Creek, a natural bay. This bay, where the water is very shallow, and which is of large extent, appears to have been admirably adapted by nature for the purpose of a dry dock or shipyard. There is ample room between the ship channel and the shore. No streets or railways intersect the site. The river is wide and the current very gentle.

The site is connected with the harbor commissioners' independent railway tracks, which themselves connect with all Montreal railways. The important main lines of the street railway service pass close to the site. The new and extensive works of the Montreal Steel Works or Canadian Steel Foundries, Ltd., which will be one of the most up-to-date steel plants on the continent, are rapidly nearing completion, just across Notre Dame Street, the extensive Locomotive Works, Structural Steel Works, National Bridge Co., and the Canada Cement Co., besides a host of other manufacturing industries attracted to this locality, are branching out and flourishing in this immediate neighborhood.

Considering, therefore, labor conditions, access by railways and steamships and the physical suitability of the site, the construction of the Dry Dock Works is meeting with unanimous approval.

The harbor commissioners are supplying the protected basin, wharves and deep water, as well as an area of 30 acres of made land for shipyard and subsidiary plant.

Messrs. Vickers, Ltd., the celebrated shipbuilding firm, of England, through the newly-organized firm of Canadian Vickers, Ltd., under contract with the government and the harbor commissioners, are to construct and maintain the floating dock and a magnificent shipyard and repair plant.

"Sir Hugh Allen" Towing Dredge from Quebec to Montreal.

The unusual features in connection with this construction job are the deep dredging; the tremendous amount of filling in, disposing of the dredged materials so as to make valuable land for the ship yard, and the construction of 2,500 feet of standard cribwork and concrete quay walls.

General Items of Construction.—Two reinforced concrete one-story transit sheds are under construction on the Tarte

Pier, and are sufficiently advanced to assure their availability early next season.

A new ferry wharf, a locomotive round house and shop, a new 10-ton electric hoist and dredges under construction will, in addition to the larger items of construction, be of interest to civil, electrical and mechanical engineers.

With the exception of buildings and steel hulls, all the harbor commissioners' construction and repair work is carried on departmentally, and plant belonging to the organization consists of a very complete and up-to-date equipment.

The new and powerful tug "Sir Hugh Allen," built for the harbor commissioners in 1911, completely fulfilled the expectations and requirements. Received in July, this tug was immediately put to work towing scows up the St. Mary's Current, towing the floating crane between Montreal and Sorel and Quebec, and handling and towing dredges.

This tug, strengthened for ice work, made a record by sailing from Montreal to Pointe-aux-Trembles on New Year's Day, 1912, the river being still open.

During the season a total of 1,805,340 cubic yards were dredged; a total of 28,934 cubic yards of concrete were constructed by the departmental force of the commissioners; a total of 3,290,470 cubic feet of crib work constructed; a total of 1,229,620 cubic yards placed in the embankments and reclaimed land areas by derricks and 2,562 lin. feet of quay wall constructed.

A maximum number of 1,233 men were engaged, not including work being carried on by contract or the special force engaged on Elevator No. 2.

The important items of material were all purchased by public tender, including 12,300,000 ft. B.M., of timber; 42,000 tons of broken stone; 24,000 tons of unbroken stone; 31,490 cubic yards of sand and gravel; 82,000 barrels of cement; 275 tons of steel and iron castings; 2,000 tons of steel and iron bars; 16,000 tons of steam coal; 700 tons rails and fastenings, and 325 tons of wharf spikes and nails.

The season of navigation for 1911 opened by the arrival of the first trans-Atlantic steamship, the "Royal George," of the Canadian Northern Steamship Co., and navigation is still open, the commissioners having made an inspection of the harbor on January 1st, 1912.

PROGRAMME OF THE TWENTY-SIXTH ANNUAL MEETING, CANADIAN SOCIETY OF CIVIL ENGINEERS.

The annual meeting for the election of officers and members of council for 1912, and for the transaction of business, will be held as follows in the rooms of the society, 413 Dorchester Street West, Montreal.

Wednesday, January 24th.—10 a.m. Meeting for the nomination of scrutineers, receiving the report of council reception and discussion of reports of committees, and transaction of the general business of the society.

1 p.m. Adjournment for members' luncheon in the Windsor Hotel, Montreal, to which the visiting members are invited by the members resident in Montreal.

3 p.m. Continuation of the business meeting for the discussion of reports, etc.

4 p.m. An address by the retiring president, Mr. C. H. Rust.

8 p.m. Address by Dr. H. T. Barnes on "Iceberg Detection in Navigation," in the lecture hall of the Chemistry Building, McGill University.

9.30 p.m. Reception by the president and members of council in the Engineering Building, McGill University, and inspection of the laboratories and workshops.

Through the courtesy of the Board of Governors of the University, the building has been placed at the disposal of the society for this evening. Members and ladies accompanying them are invited to the reception and lecture. Cards will not be issued.

Thursday, January 25th.—Two parties will be formed for the purpose of visiting engineering works.

(a) The Angus shops. By the courtesy of the Canadian Pacific Railway Company, a special train will convey this party to the works, leaving the Windsor Station at 10 a.m. Dining cars will be attached to the train, and luncheon will be served during the inspection of the works.

(b) The works of the Dominion Bridge Company and the Canadian Car and Foundry Company. By the kindness of the Montreal Street Car Company, cars will be in waiting at the Windsor Hotel, and will leave there at 10.30 a.m. sharp, for Dominion. The Bridge Company will lunch this party at 1.30 p.m., and the works of the Canadian Car Company will be visited on the return journey.

8 p.m. Annual dinner in the Windsor Hotel.

Friday, January 26th.—10 a.m. Meeting for the reception of reports of scrutineers and conclusion of the business of the annual meeting.

3 p.m. Meeting of council.

By the kindness of the railways of the Eastern Canadian Passenger Association, members and their families who have paid a full one way first-class fare going to the meeting in Montreal, will be returned free on presentation of a standard convention certificate signed by the ticket agent from whom a ticket has been procured at the point of commencement of the journey. The certificate is to be endorsed by the secretary of the society, and to be vised by a special agent of the Passenger Association who will be in attendance at the meeting from 3 p.m. to 6 p.m. on Wednesday and Friday, January 24th and 26th. A fee of 25 cents will be charged by the Passenger Association in each case.

The Canadian Pacific Railway and the Canadian Northern Railway will grant a further extension of time to persons residing west of Fort William, making this free return available for 15 days after the close of the meeting; the ticket to Montreal having been purchased at any time and receipt obtained therefor on the standard convention form as above.

Tickets to the luncheon may be purchased at the rooms of the society. Prices: Luncheon $1.50 to resident members, dinner $3.00. C. H. McLeod, Secretary.

THE WINDSOR STATION OF THE CANADIAN PACIFIC RAILWAY AT MONTREAL.

When a company has 75,000 employees on its pay rolls it becomes a big problem to keep strict account of their doings, and when, as in the case of the Canadian Pacific Railway, these employees are scattered over practically the whole world, the office space required to properly tabulate information regarding them is enormous. In the earlier days of the C.P.R., when a ten per cent. dividend, as well as the hundred millions earnings per annum were a matter of years, the office problem was of not so serious a nature, but within the last decade the volume of business passing over the company's lines has been so great, and its many side interests have paid so handsomely, that its staff has increased by the thousands, necessitating a corresponding increase in office space. We have had an example of this only recently in Toronto, where the C.P.R. is erecting a sixteen-story building at the corner of King and Yonge Streets.

Another example is afforded in Montreal. In this city alone, there are 12,000 people in the employ of the C.P.R., and while these do not all work under the same roof, it has

been found necessary to build a huge extension to the Windsor Street station, in order to properly look after the work and general conduct of the company's employees.

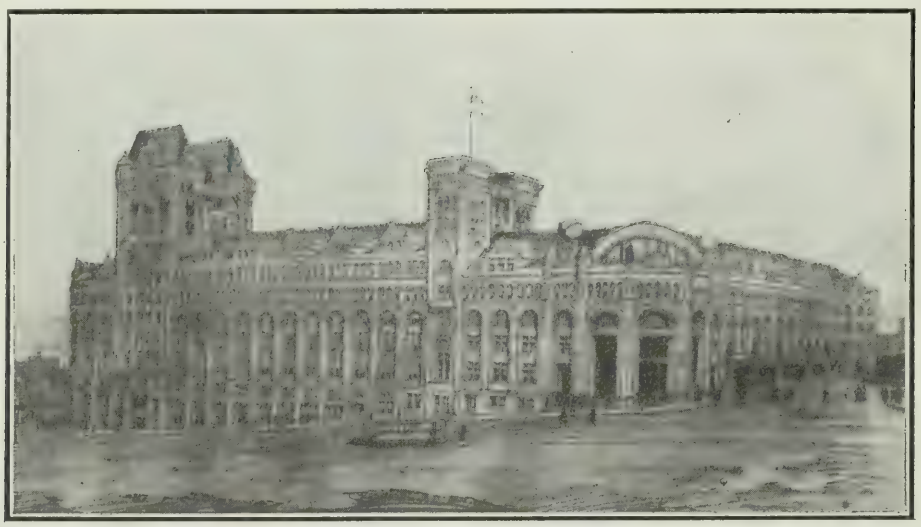
The history of the Windsor Street station is practically the history of the C.P.R. itself. The first and original Windsor station, erected in 1889, was only a small affair, but as the company's business grew it was added to until this, the fifth extension, will make it the largest and most complete railway station in Canada.

The present building is situated on the southwest corner of Windsor and Osborne Streets, and the extension is being built just south of this, so that the new station extends from Osborne Street on the north to St. Antoine on the south, and from Windsor on the east to Mountain Street on the west. The extension proper has a frontage on Windsor Street of 293 feet, and on Osborne of 850 feet, so that taking into consideration the offices now occupied by the Dominion Express Company on Osborne Street, the station, as it will be when the extension is completed, will have the following frontages: on Windsor Street, 493 feet; on St. Antoine, 175 feet; on Osborne, 850 feet. This gives the station a ground floor area of 77,000 square feet.

crete work has also been completed, including the building of a huge viaduct for the carrying of the tracks. This viaduct was rendered necessary by the Windsor Street grade, the tracks having to be brought in at a height of about forty feet above St. Antoine Street, in order to have them on a level with those now in use. The foundations of the building are the heaviest ever built in Montreal, the concrete piers going down forty feet to solid rock.

Plans for the whole interior of the building have not as yet been completed, but in this connection considerable remodeling will be done in the present structure. At present the main entrance is on Osborne Street, but this will be moved directly to the Windsor Street corner, and there will also be main entrances at the foot of the tower and at the St. Antoine Street corner. The offices now used by the ticket sellers will be moved to another part of the building, and they will be greatly enlarged, and other sweeping changes will be made.

Entering from the St. Antoine Street corner the main floor can be gained either by two huge passenger elevators, or by the marble stairways on either side of the doorway. These will admit of a direct entrance to the concourse, which



Windsor Station, Montreal.

In point of height the new building is the highest in the British Empire. When the new C.P.R. offices in Toronto are erected it may possibly have a rival in this respect, but until that building materializes, Montreal has the highest building. This is Montreal's first sky-scraper. They have several of the ten-story variety, but this one is sixteen stories. In reality it has three heights. Starting at Osborne Street, Windsor Street slopes down to St. Antoine at an angle of about twelve degrees, and the building has been planned to conform with this slope, the present height of 60 feet at the corner of Windsor and Osborne. being retained, while at Windsor and St. Antoine the height is 105 feet. About half way between Osborne and St. Antoine is the tower, and here is where the greatest height is, the building towering up 214 feet from the pavement to the base of the flag pole. For sight-seers this will prove a splendid site for a panoramic view of Montreal, and long stretches of the St. Lawrence river will be visible from its upper stories.

Before work on the extension could be started, the land had to be cleared. This was a work of some dimensions in itself, as there were a number of large brick buildings on the property. Good progress was made with the work, however, and now the extension of the building is practically completed. The con-

will include the present concourse, giving it a total floor area of about 8,000 square feet. It will be 26 feet high, and will be beautifully finished. On one side of the general waiting room will be a long row of ticket offices, and from here, too, access to the ladies' waiting room will be gained. This room will be fitted up in the most up-to-date manner, and south of it will be the ladies' retiring room, the nursery, and the women's pay and free toilets.

The dining facilities will be unsurpassed. That part of the concourse floor directly over the St. Antoine Street corner will be the dining room proper, and opening onto this from the Windsor Street side will be the officials' dining room with the kitchen looking out on St. Antoine Street. Next to the kitchen will be the lunch room. This room will be about sixty feet square, anl will have a large accommodation to the space between the lunch room and the concourse.

Below the concourse floor will be the store rooms, engine rooms, and immigrant quarters. Entrance to the latter will be gained by a large elevator from the concourse and by a side entrance.

Unique heating, lighting and ventilating systems will be installed and the company is arranging for its own supply of drinking water. The architecture of the extension will conform with that of the present building.

THE MONTREAL HARBOR.

It will be a matter of regret to many of the visiting engineers representing every important centre in Canada, that during their coming visit to Montreal, to the annual meeting of the Canadian Society, the important construction works in connection with the harbor extensions will be practically closed for the winter.

The engineering features in connection with Montreal Harbor and the continuous progress of its improvements are matters which interest engineers and all other Canadians interested in the building up of this country.

A meeting in the summer season would afford an opportunity of visiting the important works in connection with the improvements to the River St. Lawrence Ship Channel and the modern aids to navigation being vigorously advanced by the Department of Marine and Fisheries of Canada, as well as the splendid scheme of extensions in full swing in Montreal Harbor.

We have asked Mr. Frederick W. Cowie, chief engineer for the Montreal Harbor Commissioners, who for many years had charge of the River St. Lawrence Ship Channel, to prepare an article on the Montreal Harbor extension works. This article will be found on another page of this issue of The Canadian Engineer, and is recommended to the attention of all those who intend to be present at the annual meeting next week, as well as to those who will not have this pleasure.

THE MONTREAL MEETING OF THE CANADIAN SOCIETY OF CIVIL ENGINEERS.

The Canadian Society of Civil Engineers again hold their annual meeting in Montreal, the birthplace of the society and home of the head office. Last year the meeting in Winnipeg, the first to be held west of the Great Lakes, was a splendid success, and it is to be hoped that this home-coming will also prosper.

The Canadian society has done a great work in drawing together and developing the social and ethical sides of the engineering profession. It comprises in its membership the best from coast to coast, and these men have striven to raise the standard of the profession to the highest point.

The engineering profession has become to-day what might be called a public utility service. The engineer, to be professionally competent, must, as Professor James Scherer so pithily puts it in a recent address to the American Institute of Electrical Engineers, be a man of affairs, versed in business usages, in economics and the history of political reform. Processor Scherer says: "The helpful engineer must be nothing less than a publicist; must not only know his own profession, but must know politics; be in touch with the spirit of the times and able to assist in a proper direction of political reform; but beyond that and above all that he must, in order to do his great work, be, to an extent required of no other profession to-day, a man of known unimpeachable integrity. When you come to the very crux of the matter, the real obstacle in the pathway of your helpfulness to the public is the stumbling-block of doubt, or lack of confidence, on the part of the people in your incorruptibility. I do not question that the character of the average engineer is far above that of the average man in the street; my point is that you must have an extraordinary hold upon the people in order to win their confidence, so that they will give into your hands the solution of obscure and complex problems with which you alone are com-

petent adequately to deal. The very nature of your profession," he continued, "should make possible the attainment of an extraordinarily high standard of character. Take your vocation in comparison with the 'three learned professions,' as they used to be known. The physician necessarily juggles with the credulity of his patient, and plays upon his foibles in order to relieve him of imaginary ailments; thus the physician is open to subtle temptations that may undermine absolute truthfulness of character. The lawyer, by the very nature of the case, must consider solely his client's point of view and become a special pleader, committed by duty to prejudice. Even the clergyman, in order to harmonize the entire body of scriptural teaching, is in danger of quibbling with his exegesis. But it is yours to seek the clear, cold truth, and to declare it without fear or favor. This is the chief glory of science, high priestess of our modern civilization."

It must be the aim of all members of the Canadian Society of Civil Engineers to foster such sentiments as the above. When the individual engineer appreciates that his character and his work must be above the breath of suspicion, then the profession will begin to come into its own. The Canadian society has done much towards raising the ethical standard, but there remains room for still greater effort.

EDITORIAL COMMENT.

We have received a copy of the first issue of the Journal of the Canadian Peat Society. We are glad to welcome this new publication into the technical journal field. Its object is to disseminate information regarding the status of the peat industry in Canada. This society and its organ deserve the support of every power user and fuel user, as well as the owners of peat lands and the manufacturers of machinery for making peat fuel.

* * * *

Moosejaw has appointed a Commissioner of Public Works. Among the applicants for the position were some of our most capable Canadian engineers. However, Moosejaw, with the characteristic loyalty of so many of our public-spirited cities and towns, chose a man from St. Paul, Minnesota. Their appointment of a city engineer will now be awaited with interest. No doubt the gentleman from St. Paul will be able to furnish them with a competent man.

* * * *

The question of an Engineering Standards Committee for Canada is suggested in a letter by Mr. Alfred S. L. Barnes. We agree with Mr. Barnes that it is time such a committee was formed. It is our impression that the Canadian Society of Civil Engineers have been working along this line for some years past. In fact, the Dominion Government, before the last election, acting on representations of the Canadian society, had given assurances that they would establish a Department of Standards and a testing station. There is no doubt that the need of a central organization is urgent, and it is to be hoped that the matter will not be dropped.

* * * *

The letter of Professor H. T. Barnes, printed in this issue under letters to the editor, is of special interest at this particular season. As Professor Barnes states, many of the large hydraulic power companies operating in Canada have little or no provision for ice protection. In the early days of hydro-electric installations, when plants were small and customers few in number, continuity of operation was not so important as it is at the present time. Some of these companies have hundreds of power users and many public utilities dependent on them. Whether it is floe ice, anchor ice or frazil ice conditions, there is usually little or no excuse for serious trouble. With reasonable care in design, by the covering of racks by the provision of ice runs and curtain walls, and by good judgment in the location and design of intake, little trouble need be experienced. It can only be classed as criminal negligence when cities and towns are without car service and light as a result of troubles due to inadequate design.

GENERAL NOTES.

The table shows for fifteen stations, included in the report of the Meteorological Office, Toronto, the total precipitation of these stations for December, 1911:—

	Depth in inches	Departure from the average of twenty years
Calgary, Alta.	0.2	—0.34
Edmonton, Alta.	0.3	—0.50
Swift Current, Sask	0.7	—0.02
Winnipeg, Man.	...	....
Port Stanley, Ont.	3.2	+0.12
Toronto, Ont.	2.85	+0.24
Parry Sound, Ont.	3.0	—1.66
Ottawa, Ont.	3.1	+0.39
Kingston, Ont.	3.5	+0.66
Montreal, Que.	4.4	+0.58
Quebec, Que.	3.6	+0.44
Chatham, N.B.	3.3	+0.12
Halifax, N.S.	3.4	—0.29
Victoria, B.C.	2.8	—3.47
Kamloops, B.C.	1.6	+0.78

CORRECTION.

In the issue of The Canadian Engineer dated December 7th, we published an article on Molybdenum. The material for this article was abstracted from a bulletin of the Geological Surveys Department of Canada, by Mr. T. S. Walker. Through inadvertence on our part, full credit was not given to the Department and to Mr. Walker. We take pleasure in making this explanation now.

SHUTDOWNS DUE TO ICE TROUBLES.

The Editor:

Sir,—In your issue of January 4th you call attention to the "shut down" of the Dominion Power and Transmission Company from anchor-ice at the intake. For some time I have wanted to draw your attention to the culpable lack of provision made at so many hydraulic works for handling ice. No producer of power has a right to have his works inoperative even a few hours a year when the comfort of human beings is jeopardized. It was sad to see so many valuable plants rendered useless this year by the sudden advent of the cold weather, but this happens year after year with painful regularity. With all that has been said and written on this subject one still sees the exposed rack bars inviting trouble from anchor-ice, and a head race or canal plugged with frazil. How long, may I ask, will it take these big companies to realize the practical value of the modern theories of ice formation, and that

preventive measures based on these are proving such a success in so many places. Careful readers of your valuable journal are certainly not kept in ignorance of modern developments in dealing with the ice question. To-day no power house properly equipped need fear a "shut down" by anchor-ice, frazil or any other kind of ice.

H. T. BARNES, D.Sc., F.R.S.

McGill University, January 8th, 1912.

MOTION PICTURES FOR ENGINEERING LECTURES.

The Editor:

Sir,—Re your editorial comment of 4th inst. on the use of motion pictures to illustrate a recent lecture of the Canadian Society of Civil Engineers, you mention that this is probably the first time they have been used for such a purpose.

It may interest you to hear that this method of illustration was used some seven years ago by the Glasgow Association of the Institution of Civil Engineers, of which association I was a member of council.

At that time moving pictures were not so efficient as they are to-day, but I still retain a most vivid recollection of the works displayed then, and can strongly endorse what you say as to the excellence of the method, especially from the point of view of a man who is trying to teach. Yours faithfully,

R. D. BROWN. City Engineer,

St. Catharines, Ont.

ENGINEERING STANDARDS COMMITTEE.

The Editor:

Sir,—Will you allow me to suggest through the medium of your paper that it is time that Canada had an "Engineering Standards Committee" of her own, something like that which has been in existence in London since 1901?

For the information of those of your readers who are not acquainted with the work and constitution of the British committee, it may be stated that it is supported by H.M. Government, the Institutions of Civil Engineers, Mechanical Engineers, Naval Architects, Electrical Engineers, and the Iron and Steel Institute, as well as by nearly all the leading railway companies, engineering and shipbuilding firms of Great Britain. The India Government also makes a yearly grant.

The work of the committee covers a wide and ever-enlarging field, as the following selection of the titles of some of the already published reports will show:—

Specifications and Sections of British Standard Tramway Rails and Fishplates.

British Standard Tables of Pipe Flanges.

British Standard Specifications for Portland Cement.

British Standard Specifications and Tables for Telegraph Material.

Tables of British Standard Whitworth Threads.

Tables of British Standard Fine Threads.

Tables of British Standard Pipe Threads.

British Standard Specification for Cast-iron Pipe for Hydraulic Power.

The committee also recognizes the necessity of keeping abreast of the times, as is made clear in the following extract from its "Report on Work Accomplished," dated 1911:—

> " . . it is necessary to review from time to time the original standard specifications, and unless this be a recognized part of the work of the committee, the process of standardization might lead to undesirable stereotyping of procedure, checking inventions and impeding improvements."

From Canada's point of view the extract below from the same report is of great significance:—

> "A comparatively new branch of the committee's activities is the co-operation which it has been asked to extend to the subject of International Standardization, and the secretary has attended, in an advising capacity, congresses held at Copenhagen, Brussels and Paris. **One salient feature which has been evident at these Congresses is the advantage which this country enjoys over most of the Continental countries in the possession of a central organization on which all the interests concerned are represented, and to which reference can be made and information obtained as to the reasons which led to the determination of the present British Standard."**

The italics are the writer's, and are employed to give emphasis to the opinion expressed in this portion of the paragraph, more especially in view of the fact that a Canadian Committee of the International Electrotechnical Commission is now in existence and has held its first meeting.

This country, so far, has been content, and perhaps unavoidably, to adopt standards made by other countries without question, but the time is coming, if it be not already here, when there will be British Standards for one thing and American Standards for another, with perhaps a few international ones thrown in. No one will know the why or the wherefore of the Standards. and it is not unlikely that by means of such a haphazard kind of selection the standards which would be the best for this country will, in some instances, be the very ones that are not adopted.

It will not, in many cases, be essential, if an Engineering Standards Committee be formed here, that such a body should itself go over the whole ground of discussion and experiment which has led to the adoption of standards in other countries, but it could, after due consideration of the existing standards of other countries—and having in mind any requirements peculiar to Canada—decide whether to adopt an existing standard or to frame a fresh one. The writer believes that this subject has already been mooted in some quarters, but, as far as he is aware, it has not yet been given any publicity. The proper time for the formation of such a committee is now; its work will be much harder five, or even two, years hence. Government support, both Dominion and Provincial, should be asked from the commencement, and also that of all leading railway companies, engineering societies and manufacturers, telephone and telegraph companies, etc., in the Dominion, as each of them would derive very great benefit from the labors of such a committee.

Another reason for the necessity of prompt action in this matter is the proposed formation of various Provincial Commissions to take charge of "public utilities." These Commissions will probably each begin to formulate their own standards, and in a few years there will be in existence a state of "confusion worse confounded."

Your correspondent would be glad to do anything in his power to further the formation of such a body. Yours faithfully,

ALFRED S. L. BARNES,

Room 512, Continental Life Building, Toronto.

FOUNDATION WORK IN MONTREAL.

By ALEXANDER ALLAIRE, M.E., Manager of The Foundation Company, Limited.

In designing foundations for heavy structures, the engineer has before him in each specific case two problems; first, that the type finally selected shall fulfill all the necessary conditions, and second, that this shall be accomplished with a minimum expenditure of money.

In arriving at the result, both of the above are governed by the following:—

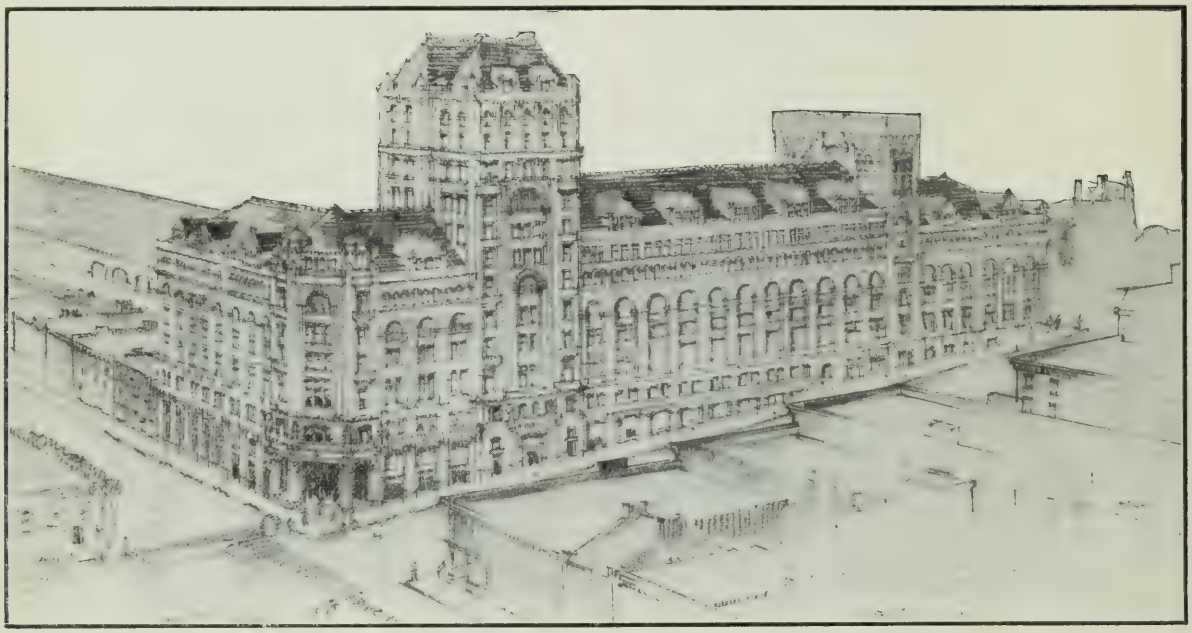
1. The nature of the soil.
2. The depth of rock or satisfactory bottom.
3. The magnitude and distribution of the loads to be supported.
4. The elevation of water level.
5. The depth of the general excavation.
6. The surrounding conditions, including the possibility of future disturbance.
7. The value of the structure to be supported.

precautionary method usually consists in carriyng the foundation to a depth sufficiently great to preclude any possibility of future disturbance.

The recognized types of foundations may be grouped in well defined classes. These are essentially as follows:—

Class 1.—Spread Footings.—Under this head we have (a) timber grillage; (b) plain concrete footings, and (c) reinforced concrete footings. These comprise the ordinary building foundations.

Class 2.—Piles.—This is divided into (a) wooden piles; (b) concrete piles, both those moulded in the ground and those built up and allowed to set before driving; (c) steel pipe driven, interiors cleaned out and filled with concrete. This kind of work is more expensive than the previous class, but often permits building where under the former it would be impossible.



General View of Windsor Station.

The careful consideration of these seven factors must be considered as essential to the successful working out of a proper design.

In item number "six" we have a point to which enough thought is often not given. Frequently the study of the foundation for a structure shows that two types may be used, often one less costly than the other.

Here the fact that apparently the result may be obtained with a smaller expenditure of money would seem to govern. A further investigation of the surrounding conditions, however, often shows that the apparent first saving is not the governing element. The modern tall building, costing as it does, hundreds of thousands and often millions of dollars, makes it imperative that this large investment shall not be jeopardized. When, therefore, the examination of the adjoining properties and neighboring streets indicates the probability of future operations which may endanger the stability and safety of the structure, it is often necessary to accept what appeared to be at first the more expensive design. This

Class 3.—Open Method—Which may be sub-divided into (a) cofferdams of wood or steel sheeting; (b) open excavation followed by timber lining; (c) timber or steel box built up above ground and sunk, (d) monolithic concrete caissons built up above ground and sunk. The foundations are often carried to considerable depth below the ground line.

Class 4.—Pneumatic Method.—(a) Caissons of timber or steel filled with concrete before sinking; (b) monolithic concrete caissons built up before sinking. These foundations are usually carried to rock.

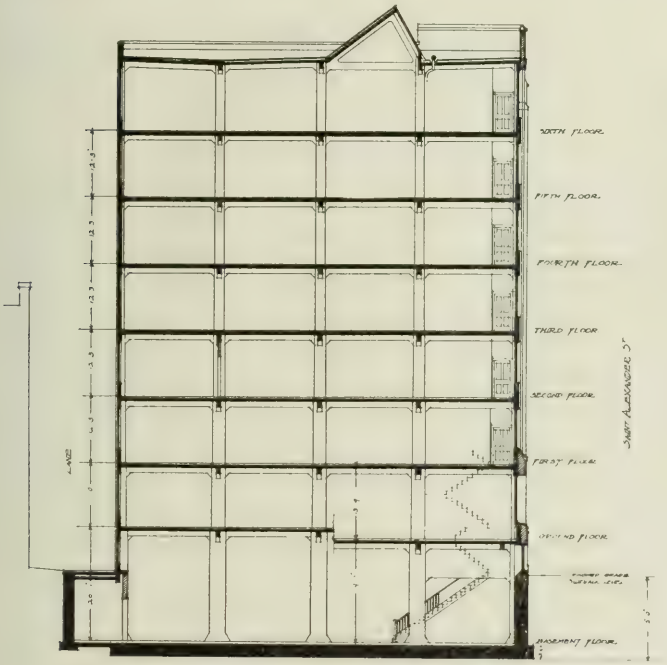
Class 5.—Which consists of a combination of two of the above classes, usually II. and III., or by starting with III. and finishing by means of the pneumatic method.

The city of Montreal, lying in good port between Mount Royal on one side and the St. Lawrence River on the other, presents to the engineer soils of widely varying character. We are told that ages ago this section of the country formed a part of the Gulf of St. Lawrence, and at that period the water level was practically at the top of Mount Royal. As

the centuries passed this water receded, during certain periods more or less rapidly, while at others it remained practically stationary. The periods of stationary and falling water levels were clearly shown by well defined beach or shore lines found in recent investigations.

As a result of the above, the blanket of earth, covering the rock underlying Montreal, is not a uniform quality over the whole area of the city. Usually the rock is found to be overlain with a shallow layer of boulder clay left from the glacial period, while over this the soil is of various natures, depending upon the localities. Excavations in various parts of the city show this to consist of loam, sand, gravel, soft and medium clays, as well as quicksand and a silty clay resembling quicksand.

The upper stratum of limestone underlying the city is also worthy of consideration. In constructing the foundations for certain buildings, whose weight made advisable the carrying of the piers to rock, The Foundation Co. found the upper surface of this rock to be badly shattered, necessitating the excavation of same in some instances for a number of feet



Section Through Herald Building, Montreal.

before a satisfactory bottom could be secured. This, geologists tell us, is due to the upheaval at the time that Mount Royal, formed by some volcanic eruption, burst its way through the overlying rock strata.

As a result of the varied character of soils to be encountered in the different parts of the city, we find many different types of foundations. A great majority of the buildings having moderate height and loading are carried on spread footings. These are to be seen daily in the course of erection and need no further comment.

There is one type of structure, however, which while it comes under this class, is not common to Montreal. This is exemplified in the Herald Building. The building in question is carried on what is known as a floating foundation; that is, the columns, instead of each being carried on an individual footing, are all set in one immense footing or mat, which covers the whole area of the lot. The reinforced concrete mat, 2½ ft. thick, at the Herald Building is built on a bed of gravel overlying black sand of considerable depth. The idea of spreading the footing, as mentioned, was to reduce the load per square foot, the loading of the soil in this case being estimated at one ton per sq. ft.

In certain sections of the city wooden piles have been used in the foundations, as these were thought to meet conditions satisfactorily. Along the harbor front several structures are carried on concrete piles, both the moulded in the ground and built-up types having been used.

At the Montreal General Hospital we have a more difficult class of foundation work. Here the open method was

Driving Steel Sheeting, General Hospital, Montreal.

used, steel sheeting being driven and the excavation made inside same down to hard pan. These piers were circular in form, though of varying diameter. The sheeting was driven to depth with both steam and drop hammers. To facilitate handling these and the pieces of steel sheeting, four stiff-leg derricks were set up at different points on the lot. On this work the average distance from the lot, as excavated, to the hard pan on which the piers were started, was approximately 30 ft.

The Windsor Street extension is another example of the open method, differing, however, in manner of execution from that just described. This work comprised the construction of approximately 300 piers, a few rectangular but most of them circular in form. The Foundation Co. started on this work the latter part of November, 1909, and finished

Windsor Station Extension, Work in Progress.

about June 1st, 1910. This is particularlyy noteworthy when the season of the year, during which the work was carried on, is considered.

The pier excavations in this instance were made by open digging and lining the sides of the wells with wooden lagging, which was held in place by iron bands. The material was hoisted to the surface in buckets by means of a revolving winch head mounted on a tripod at the top of each well. The pits were excavated in sets of from 7 to 9, each row having a hoisting engine, which by means of an endless cable, furnished the power to turn the winch heads. Five complete outfits of hoisting engines and tripod sets were used, so that while 4 rows of holes were being operated a fifth could be prepared. This precluded any loss of time as the gangs coming out of the completed piers immediately started in on the row of holes which had been made ready.

On this site, as the excavation of a great number of piers was completed, and the rock bared, it was found that its upper surface was broken up by very noticeable cracks. It was, therefore, necessary to remove this faulty material down to a sound strata. In some instances the excavation was carried to a depth of twelve feet before a satisfactory bottom was secured.

At the Dominion Express Building, corner of St. James and St. Francois Xavier Streets, we have an example coming under Class IV. Here The Foundation Co. sank pneumatic

Dominion Express Building, Montreal.

caissons to rock, each forming a pier on which rested one of the building columns. These caissons were built with wooden walls filled with concrete. As the work was carried on during the winter of 1910-1911, these walls protected the concrete from the cold weather. The setting up of the concrete was further aided by hanging salamanders, in which fires were kept burning, in the interior of the caisson shaft. The total number of caissons sunk was 42.

The depth of rock was found to vary somewhat over the lot, the deepest caissons reaching same at a distance of 90 ft. below St. James Street curb. The extreme dimensions of the lot were 120 ft. by 95 ft. It was bounded on three sides by streets and on the remaining side by the Royal Bank. On account of the columns along the Royal Bank being very close to the building line, it was necessary to set these caissons back the necessary distance to clear the wall. The new columns then being thrown off the centre of the piers, were cantilevered by means of girders composed of 24-inch I beams extending from these caissons to those in the next row from the building.

On account of the excavation having to be carried below the footing of the Royal Bank, it was necessary to take care of the building while the work was carried on. This was very successfully done by means of long inclined pushers, these being adjusted to preclude the possibility of any settlement.

At this building, also, the upper surface of the rock was found to be badly fractured at a number of the pier sites. This condition did not extend over the lot, being confined to the northeast corner. Wherever this was found to exist, however, the rock was taken out under air by means of blasting, assisted by bull points and wedges.

The modern tall building, representing, as it does, such a large investment of capital should receive very exhaustive study before any particular type of foundation is decided upon. It is in this connection that the taking of careful borings or sinking of test pits is strongly recommended. In underground or sub-aqueous work the unknown is always likely to prove a large factor. Borings or test pits carefully made and the records obtained carefully read, will often cut down the unknown contingencies and thus aid in the design of a proper and lasting foundation.

MEETING OF CANADIAN RAILWAY CLUB.

The Canadian Railway Club held a meeting at the Windsor Hotel, Montreal, on Monday, December 18th, 1911.

Mr. E. B. Tilt, engineer of tests, Canadian Pacific Railway, read a paper on "The Work of the Testing Department of a Railway." In the opening of his paper he drew the attention of his audience to the early history of the steam railway and gradually working up to the importance of his title, showed that the management of the Canadian Pacific Railway had early recognized the value of a railway testing department, and since 1891, when W. Bell Dawson started the first laboratory, with Milton L. Hersey as assistant chemist, there has been a department of some magnitude, greater or less, depending upon what purchases of supplies were being made. Within the last few years there has been a division of the system into western and eastern lines, the former of which has had its own chemical laboratory at Winnipeg since 1905, which has specialized in water troubles with much success, in addition to doing the other routine work which comes to a railway chemical laboratory. The work on eastern lines is done conjointly, by commercial testing companies who do all of the foreign mill inspection; Dr. Milton L. Hersey and associates, of Montreal, who do all of the chemical work; and the testing department with laboratory at Angus shops, who do a portion of the domestic mill inspection, and who take charge of the routine sampling and inspection of materials received at the Angus shops, where are located the locomotive and the car departments and the general stores. The duties of the Angus shops testing department include also the preparation of suitable specifications, the investigation of the failures of materials and the studies of processes or special materials. The testing of devices is handled by the mechanical engineers of the locomotive or the car departments.

In the purchase of materials of such wide variety and origin as are required for the C.P.R. the question of economical inspection is important and the present organization has been found to be a satisfactory and cheap one.

The president, Mr. A. A. Goodchild, was in the chair.

THE MONTREAL FILTRATION WORKS.

By FREDERICK E. FIELD, Resident Engineer.

Historical.—The present water supply of the city is drawn from a shore intake about two miles above Lachine Rapids. It is a mixture of waters from the St. Lawrence and Ottawa Rivers, which above this point have a combined drainage area of about 570,000 square miles and a combined population of 172,000 contributing sewage to the rivers. The extension of the intake to a point 1,200 feet from shore is now under contract.

The water is conveyed to the low level pumping station at Point St. Charles, a distance of about five miles, by an 8½-ft. concrete conduit which parallels the power aqueduct which delivered water to the wheels of the original pumping station.

At the Point St. Charles pumping station five steam pumps are in service to elevate the present daily consumption of 44,000,000 gallons to the distributing reservoirs of the city. The municipal plant supplies a population of about 350,000, and the remaining 200,000 residents of the city are supplied by The Montreal Water & Power Company, a private corporation, which is now completing a filter plant of 20,000,000 gallons daily capacity.

Owing to the striking increase in the number of typhoid cases which happened towards the end of the year 1909, the newly-elected Board of Commissioners at the beginning of 1910 decided to confer with experts of high repute as to the study of the present and possible sources of supply of the aqueduct of Montreal. Meantime, on February the 8th, 1910, the treatment of the municipal water supply by hypochlorite of lime was started and has been regularly continued up to the present time.

On April 4th, 1910, Messrs. Hering & Fuller. consulting engineers, of New York city, were instructed to report on the best means of securing an improved water supply for the city.

On July 2nd, 1910, the consulting engineers submitted their report and recommended double filtration of the St. Lawrence River water. This recommendation was adopted by the city, and Messrs. Hering & Fuller were engaged to cooperate with Mr. George Janin, chief engineer, and Mr. T. W. Lesage, engineering superintendent of waterworks of the city, in preparing contract plans and specifications, and in supervising the construction of filtration works for the city of Montreal.

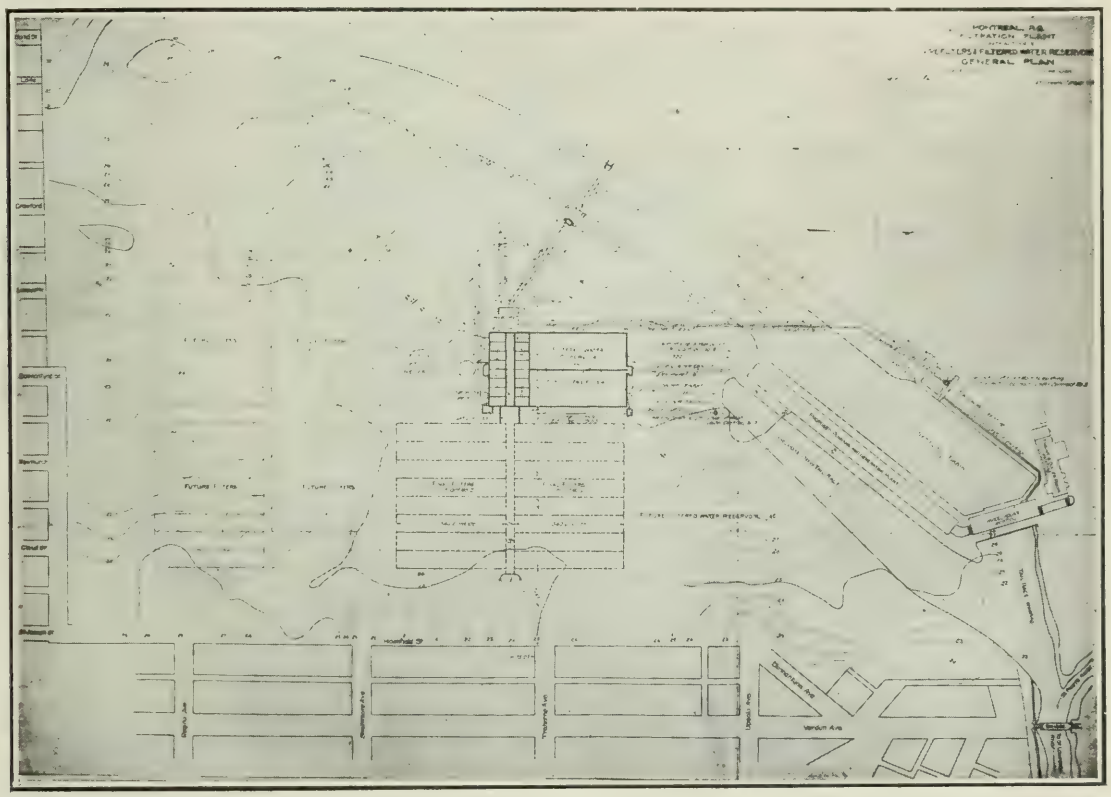


Fig. 2.

The work has been divided into four contracts, in order to facilitate the rapid and economical completion of the project.

Contracts.—Contract No. 1, for the pumping machinery, blower, and cranes was awarded on August 9th, 1911, to the British Electric Plant Co., of Alloa, Scotland, for the lump sum of $40,250.

Contract No. 2, for the final filters and appurtenances, was awarded on August 16th, 1911, to F. H. McGuigan, of Toronto, for the lump sum of $673,000.

Contract No. 3, for the prefilters, filtered water reservoir and appurtenances was awarded on 16th December, 1911, to F. H. McGuigan for the lump sum of $485,000.

Contract No. 4, for the pumping station, wash water tower, and the superstructures of the various buildings and gate chambers, has not, as yet, been placed under contract.

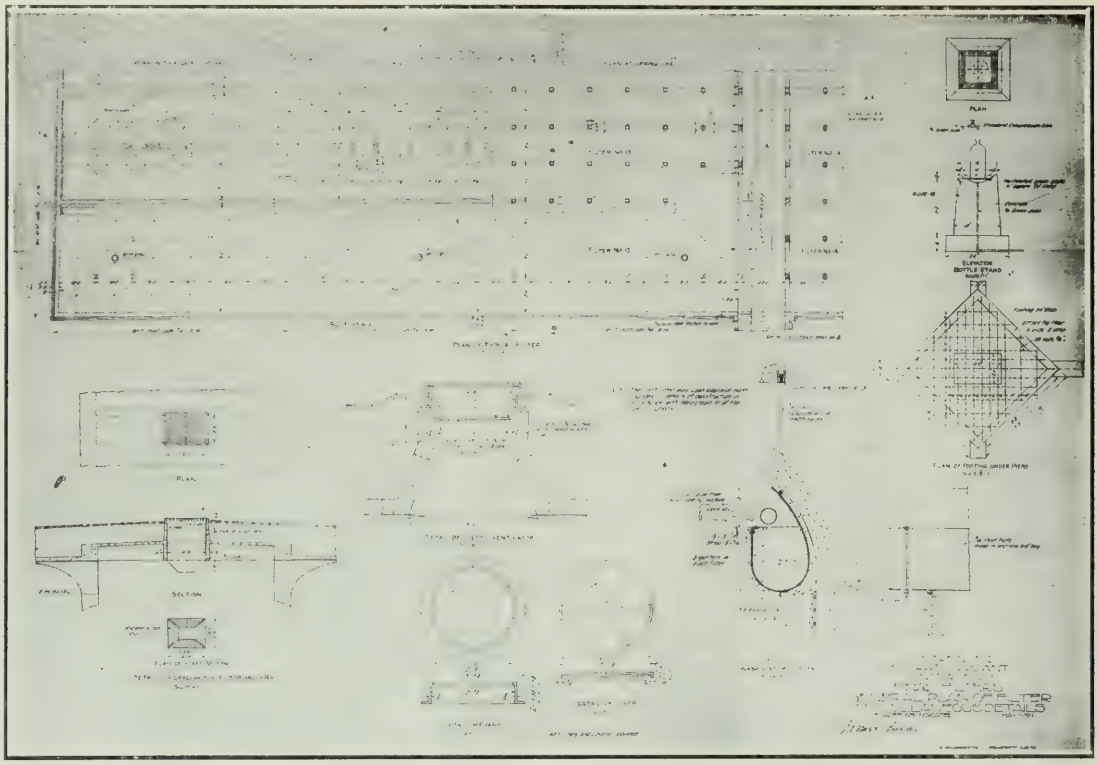
The work will be built on land in the town of Verdun and adjoining the city water works property at Point St. Charles. The general arrangement of the several parts of the work are shown in Fig. 2.

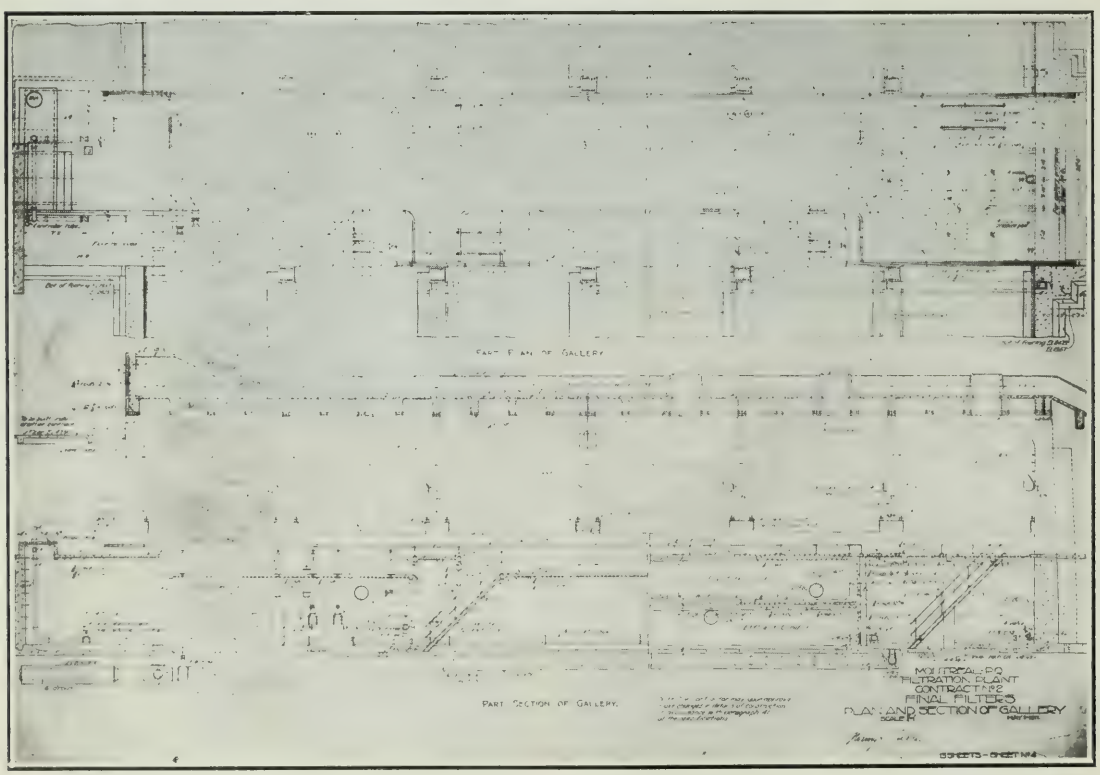
The present construction is designed for a daily capacity of 50,000,000 imperial gallons (60,000,000 U.S. gals.), and will serve about 350,000 people. Sufficient land has been acquired, and provision has been made in the present plans for enlarging the works, as required by future needs, to an ultimate daily capacity of about 150,000,000 imperial gallons.

Contract No. 1—Pumping Machinery.—This contract includes:—

Two raw water pumps, unit capacity 17,500 imperial gallons per minute.

Two raw water pumps, unit capacity 17,500 imperial gallons per minute.





Figs. 3 and 4.

Two raw water pumps, unit capacity 5,800 imperial gallons per minute.

Two wash water pumps, unit capacity 1,300 imperial gallons per minute.

Two sump pumps, unit capacity 330 imperial gallons per minute.

Two sump pumps, unit capacity 150 imperial gallons per minute.

One rotary blower, unit capacity 5,000 cubic feet of free air against five pounds pressure per square inch.

Two cranes, hand operated, each six tons capacity.

Switchboards, transformers and appurtenances.

All pumps are horizontal, except the sump pumps, and all, together with the blower, are driven by direct connected three-phase 60-cycle alternating current motors.

The voltage for the 8 largest pumps and the blower will be approximately 2,200. That for the remaining 6 pumps will be approximately 550.

The ordinary lift for the raw water pumps is 18 feet, for the wash water pumps 46 feet, and for the sump pumps 15 feet. The raw water pumps receive their supply from a connection with the present raw water conduit previously mentioned, and have no suction lift.

Contract No. 2—Final Filters and Appurtenances.—The final filters are 16 in number and are arranged in batteries of 8 on either side of an operating gallery. The filters are covered by groined arches, supported on piers spaced on 19 feet centres. The floor is flat and so constructed that the pier load is carried on foundation blocks, independent of the rest of the floor. The filters are 55 by 340 feet inside, with the short dimensions adjoining the gallery to accommodate the design to the use of the Blaisdell washing machines, which will run from the gallery to the extreme end of the filters upon tracks carried by concrete beams between the filter piers. The underdrainage system consists of two half-round 8-inch laterals in each bay, which discharge into a central main collector, 2½ feet in diameter, extending the entire length of the filter and below the filter floor.

The filtering material comprises 12 inches of gravel and 27 inches of sand.

The gravel will be placed in four layers. The lower layer, 5 inches thick, has particles varying from 2½ to 1½ inches in size.

The second layer is 3½ inches thick and varies from 1½ to ½ inch.

The third layer is 2 inches thick, with particles from ½ inch to 9/32 inch in size.

The fourth layer is 1½ inches thick and has particles from 3/16 inch to 5/64 inch in size.

The filter sand will vary from 0.25 to 0.36 mm. in size.

The filters receiving their supply from the prefilters to be built under Contract No. 3, will operate at a rate of 10,000,000 gallons per acre per day, thus giving each of the 16 filters an output of 3,750,000 gallons per day.

The operating gallery, with a clear span of 22 feet, contains the prefiltered and filtered water conduits and the necessary pipe connections to the filters.

The side walls carry tracks upon which a transfer table, for conveying the washing machines from one filter to another, will be operated.

The filters and gallery are lighted by electricity, and the gallery also has skylights for natural illumination.

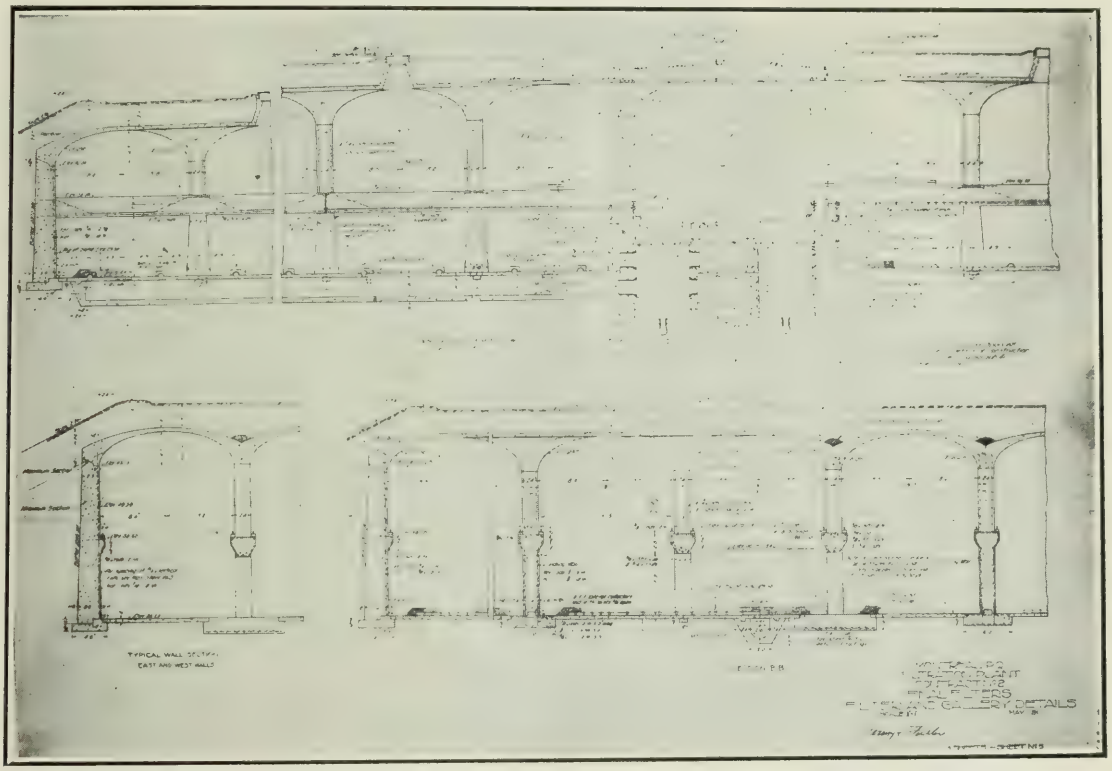


Fig. 5.

A heating and ventilating system will be installed to prevent the formation of skim ice on the filters during cold weather, and to make the filters and gallery hygienic for workmen at all times.

From a fan, with a capacity of 65,000 cubic feet of air per minute, installed in an adjoining gate house, the air electrically heated will be conveyed in plaster ducts along the end walls of the filters. Between each row of piers an opening with an adjustable door will allow the heated air to pass into the filter.

On each side of the gallery and in the arch of the filter roof a similar duct takes the air back to the fan.

Electric radiators are also provided in the lower part of the gallery to prevent the freezing of gauge and controller piping.

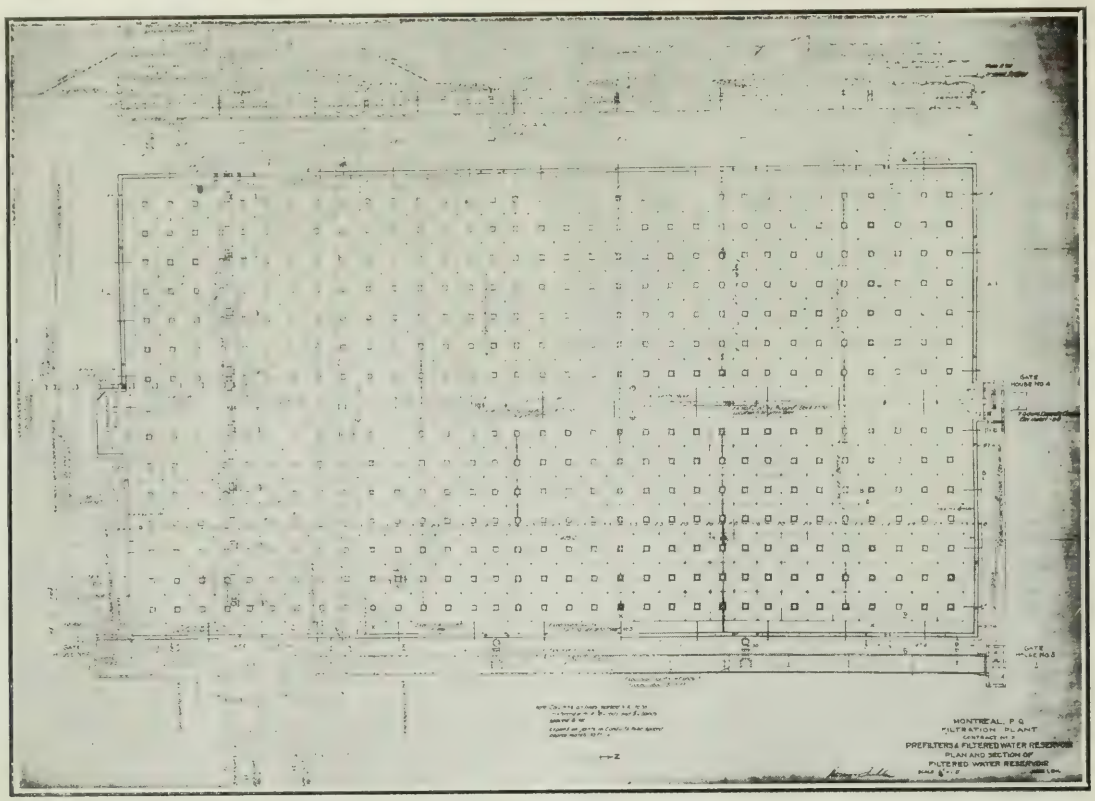
Figures 3, 4 and 5 give many details of the design of the final filters.

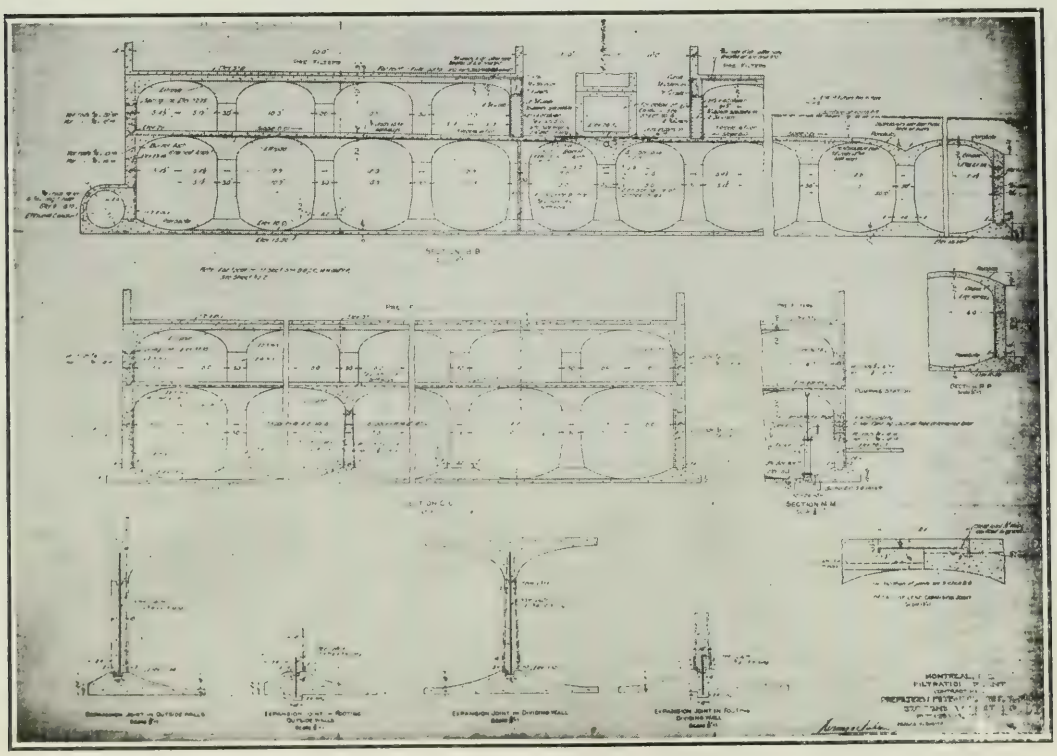
Contract No. 3—Prefilters and Filtered Water Reservoir.—The prefilters and filtered water reservoir are to be built just west of the final filters, and between them and the aqueduct.

The filtered water reservoir is of concrete, with groined arches for the roof and inverted groined arches for the floor.

ed on each side of the operating gallery, which is practically a continuation of the gallery of the final filters.

The floors of the prefilters are carried by a second series of groined arches, 8 feet above the roof of the filtered water reservoir.





Figs. 6 and 7.

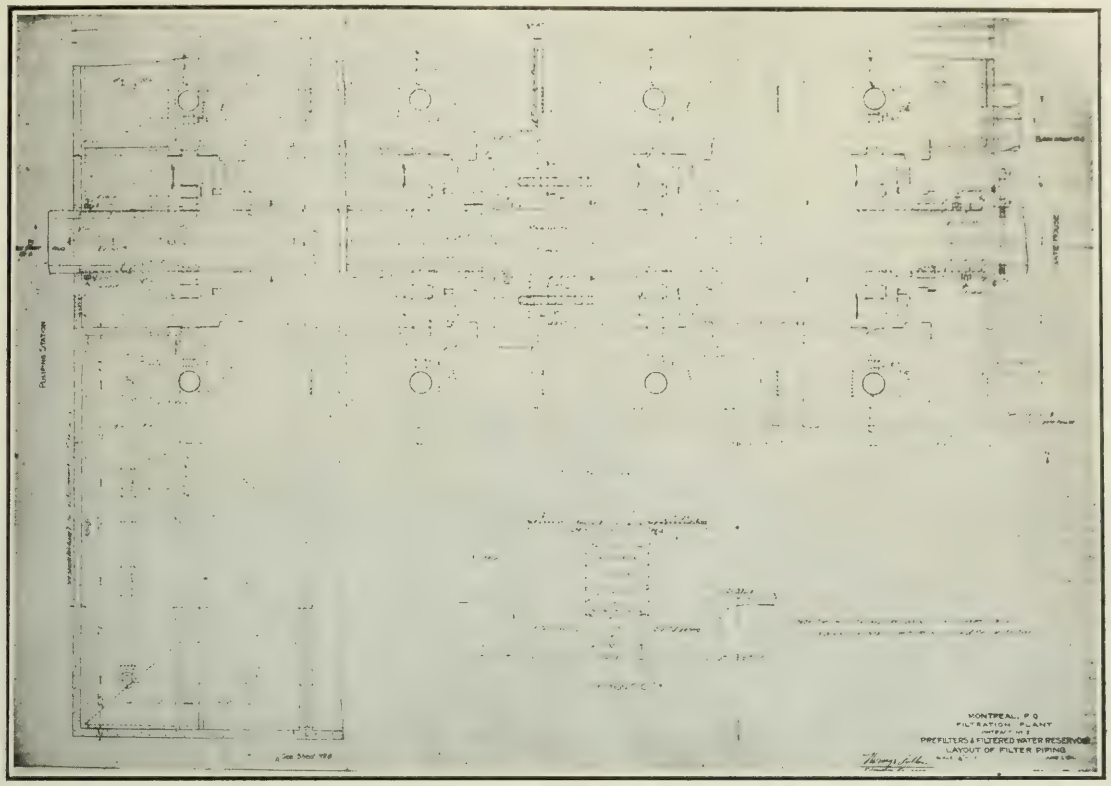
It is 429 by 232½ feet in size, and has a capacity of 7,500,000 gallons. The roof is designed to take the load of the present and future installations of prefilters. The prefilters now under contract are 16 in number, and are arrang-

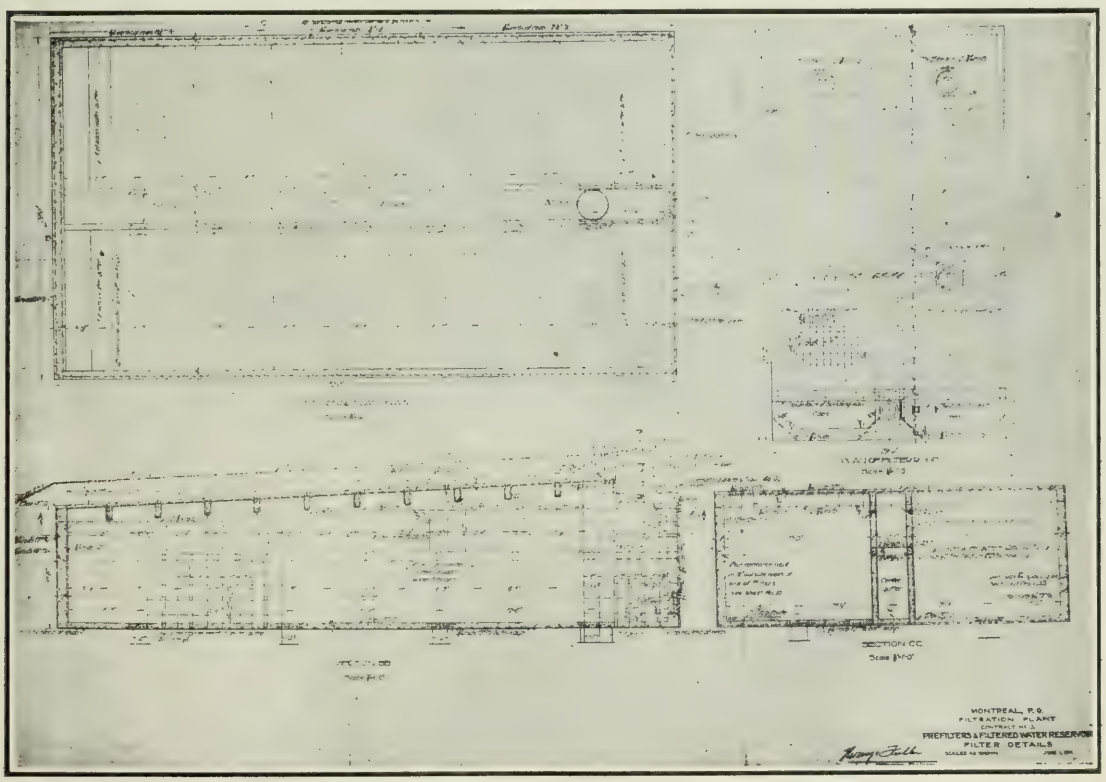
Each prefilter has an effective sand area 50 by 24 feet, which is divided longitudinally by a central wash water gutter, the sides of which extend above the normal water level of the filters.

Each prefilter has 8 lateral wash water gutters on each side of the central gutter.

The filtering material consists of 8 inches of gravel and 30 inches of sand.

Each prefilter will be equipped with a strainer and air system. Water for washing will be supplied from the wash water tower, to be built under contract No. 4, and fed by duplicate motor driven pumps, already mentioned under the





Figs. 8 and 9.

The gravel will be placed in four layers, varying in size from 1 inch in the lower layer to about 0.1 inch in the top layer.

The sand will have an effective size of from 0.50 to 0.60 mm.

description of Contract No. 1.

The air will be supplied by the rotary blower, previously mentioned.

The prefilters are designed to operate at a rate of about 136,000,000 gallons per acre per day. Each filter unit will

be equipped with a rate controller, which will allow the passage of 3,750,000 gallons daily, the same rated capacity as each of the final filters.

The operating gallery contains the influent and effluent conduits, piping connections, and the operating tables from which all operations for the regulation and washing of the filters are accomplished by means of connections to hydraulically operated valves.

On this contract as well as on contract No. 2, all piping or conduits larger than 30 inches in diameter, are of reinforced concrete.

All work has been designed with the idea of the greatest possible elasticity in operation.

Either the prefilters, final filters, or filtered water reservoir could be put out of service if desired, and the building of such extensions of the works as the future may require can be accomplished without affecting the capacity of the present plant.

Figures 6, 7, 8 and 9 give details of reservoir and prefilters.

Contract No. 4—Pumping Station and Buildings.—This contract, not yet executed, will include the pumping station, the wash water tower, and the buildings over the operating gallery of the prefilters and over the gate chambers.

The buildings will be of concrete or brick, with either red or green tile roofing laid upon roofs of cinder concrete.

The roof trusses will be of structural steel shapes.

In the wash water tower, equipment will be installed for the treatment of the filtered water with hypochlorite of lime, if such treatment is required after the double filtration of the water.

Part of the main floor of the pumping station will be fitted up as a chemical and bacteriological laboratory.

The building will be heated, if required, by electric radiators.

Associated Work.—A hydro-electric pumping station will be built on the east bank of the enlarged aqueduct, near the old wheel house.

This station will furnish electric current to run the pumps and machinery, and to light and heat the several units of the filtration works. It will also receive the filtered water from the works, and pump the same to the distributing reservoir of the city.

As all the filters and the filtered water reservoir are covered with earth and seeded, it is proposed to construct roads and paths about the works, plant trees and shrubbery, and, in fact, create a park which will compare favorably with the other parks in the city, and be beneficial to the people in this vicinity.

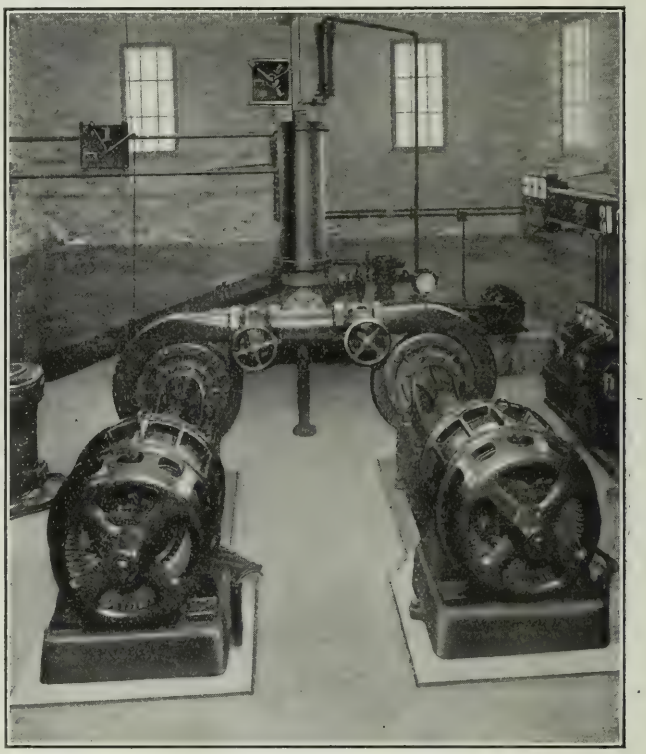
UNIQUE SEWAGE PUMPING PLANT.

One of the first obvious uses discovered for the centrifugal pump was the handling of water containing foreign elements that would either become lodged in the intricate passages of a reciprocating pump or be caught by the closing valves, allowing the pump to lose its suction. In modern sewage pumping stations, therefore, the centrifugal is preferred, as all foreign matter will readily pass through it.

The Sunnyside Avenue sewage pumping plant of the city of Toronto is unique. It is located at the foot of Sunnyside Avenue, on the lake shore, and drains a section of the city whose level is below that of the main trunk sewer running east and west. The difference in elevation between the bottom of the reservoir from which the sewage pumps take their water, and the main sewer is 44 feet, which requires, however, 620 feet of 8-inch pipe. The reservoir occupies the basement of the pump house, and is entirely under ground. It measures 18 feet by 18 feet, and is 10 feet deep, having a capacity of 20,000 imperial gallons.

It was possible to estimate closely the ultimate population which this station would ever be called upon to take care of, and the necessary pumps were installed in duplicate, in order that the station might never be shut down, in case one unit needed overhauling. The station being small and isolated, as far as similar city equipments are concerned, the plant was designed to (1) automatically prime its own pumps; (2) to start pumping when the water in the reservoir had risen to within one foot of the pump house floor, and (3) to stop the pumps when the reservoir had been pumped out

The main equipment consists of two 6-inch special centrifugal sewage pumps, built by the John McDougall Caledonian Iron Works Co., Limited, of Montreal. Each has a capacity of 800 imperial gallons per minute, and is direct connected to a 40 h.p. induction motor. These pumps are started and stopped by Cutler-Hammer relay starters, operated by floats that rise and fall with the level of the water in the reservoir. As the pumps operate automatically, it was considered good practice to provide considerable reserve power to allow for any possible variation in head.



Sunnyside Pumping Station.

Heretofore the city has used vertical submerged centrifugal pumps, but owing to the difficulty of reaching them if they ever required attention, and the desirability of having machinery where it could be frequently inspected, the engineers decided in favor of the horizontal type placed on a concrete floor above the reservoir, so that the motors would be in a perfectly dry location. As foot valves could not be used on the suction line to keep the pump primed, due to the fact that foreign matter contained in the water would lodge in the valve seats and prevent them from closing special device was designed which goes into operation just before one of the main sewage pumps, primes the pump, and holds the priming until the pump is in full operation. A discharge air chamber contains a set of floats which operate at the proper time, causing a small vacuum pump to exhaust

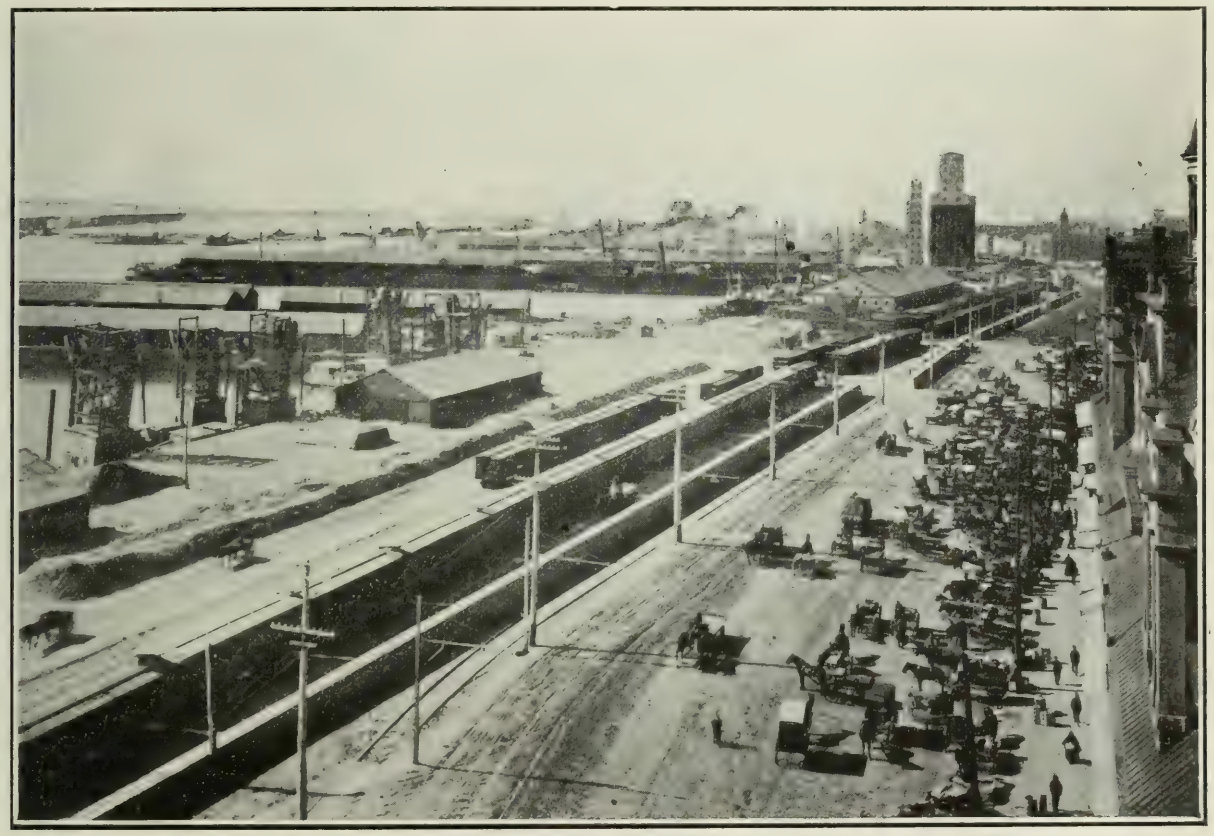
the air in the pup casings, thereby sucking up the necessary priming water from the reservoir below.

This station has now been in operation about six months and the only attention it has received is from an attendant who makes a daily inspection and sees that the oil wells do not run dry.

THE CANADIAN NORTHERN IN MONTREAL.

If a stranger were to inquire in Montreal to-day what had been the most interesting issue discussed during the year the reply would in all probability be: The Canadian Northern and its tunnel right of way into the city.

There is not any doubt about its being the most interesting piece of gossip bandied about among the odd half million inhabitants of the eastern metropolis, and it may also be fairly declared that the problem which the Canadian Northern Railway engineers have set themselves to solve is really the biggest to confront any railway in any city in Canada.



A View of Montreal Harbor.

The tunnel idea of an entrance had always, in the past, been accepted as but a remote possibility by the average railway engineer. True, the subject has probably been often discussed in the executive councils of other roads, but the thing seemed so stupendous an undertaking that it never advanced to the detailed stage, and the railways were quite content to do the best they could with the facilities they had. The Canadian Northern, however, fresh from the conquest of the western prairie, and with the determination born of a transcontinental idea urging on its men, faced the difficulty not with the "impossible" impression, but with the solid conviction that a tunnel was the only proper solution to the problem of an entrance into the heart of the city of Montreal. Mount Royal, while one of the city's most splendid assets, and prominent in Canadian annals since the very inception of the country, is undoubtedly also one of its greatest handicaps. It is not possible for any one to conceive of the city growing over the mountain, and consequently the latitude for growth had been always limited from that fact. The residences of its citizens may flank it but the limited speed of its surface traction line does not make this very desirable. The danger of congestion, for that reason became steadily more imminent.

When the first hint of the Montreal programme by the C.N.R. running into many millions was flashed over the wires to the inhabitants of that city, speculation and curiosity were born. But it is safe to say that no citizen of the eastern city dreamed even of the undertaking which is now taking shape for an entrance through the mountain. The problem was discussed in clubs, hotels, on the streets, and in every place where people congregate. It was, of course, impossible for the executives of the Canadian Northern to announce the beginning and the end of the Montreal scheme, for the difficulties always attending upon the securing of railway right of way, and of rights to do this or that, would have been increased tenfold. On no single occasion during the past year when it was necessary for Sir William Mackenzie, Sir Donald Mann, Mr. D. B. Hanna, or Col. A. D. Davidson to visit their city, did the representatives of the Montreal newspapers forget to ask subtly worded questions as to the scope of the programme which the Canadian Northern had in mind for the city. The direct answer, hoped for but hardly expected was never given, and even to this day it is not on the cards for the citizens of Montreal to understand fully the Canadian Northern entrance in detail.

As the case stands to-day Montreal without taking thought has been increased both in dignity and importance. Its borders have been enlarged and a new garden city is rapidly taking shape behind that beautiful mountain. Mr. F. G. Todd, a landscape surveyor of the city, noted for the

excellent harmony which he has worked out in other subdivisions both in the east and the west, is busy at the present moment working out in comprehensive detail, a beautiful suburb which is to stretch from Mount Royal through to the Back River. The residents of this new subdivision will undoubtedly be highly favored, for it will be quite possible when the tunnel is constructed for the business man to leave his office in the heart of the down-town district and be set down close to his home in anywhere from eight to fifteen minutes. Only the tube, which it is proposed to burrow beneath and through the mountain could make this possible, and in this connection it is safe to say that the sale of the land in question will go a long way towards meeting the initial outlay necessitated by such a large engineering programme. In the five thousand acres at the back of Montreal and in the city property which it was necessary to secure the Canadian Northern has already expended something like ten million dollars. The cost of the engineering work necessary on the tunnel, which is to be three miles in length, and for the elevated tracks in the city which will give the railway access to its steamship wharves, will probably run into ten or fifteen more, so that the entire Montreal undertaking may cost in the neighborhood of twenty-five million dollars. The engineering features consequent upon building such a long tunnel dwarf all the other details of the scheme.

In order that the Montreal project as an entity may be fully understood it is necessary to hark back into recent railway history, as far as this railway is concerned, and show some of the circumstances which have made some such proposition inevitable and imperative. The Canadian Northern Railway, proper, is located in the west, in that part of Canada which extends, roughly speaking, from Port Arthur, in Ontario, to Edmonton in Alberta. There are in those four provinces about forty-five hundred miles of road in actual operation. There are three main lines running east and west in the prairie provinces with a net-work of branch lines connecting these from the north and south, and the railway company has succeeded in girdling with steel the richest section of the western country. This road was born in 1896, and it may be said that at that time the vision of a transcontinental line connecting the Atlantic and the Pacific was also conceived in the minds of the two great founders of the Canadian Northern system. A few years ago the Canadian Northern started the construction of a line from Toronto to Sudbury—a thing apart from the western system, and apparently doomed to do only a local business. In Quebec the Great Northern Railway of Canada was taken over and extended until it connected the cities of Montreal and Quebec, under the name of the Canadian Northern Quebec, while the other line in Ontario was called Canadian Northern Ontario Railway. But these two were still widely separated in fact. Fresh in the recollection of Ontario people at least, was the awarding of contracts for a line of road connecting Toronto and Ottawa. Then there was another contract awarded to a Montreal contractor for a line skirting the Ottawa River and linking together the capital city of Ottawa and the port of Montreal. Both of these two roads should be completed during 1912, and through trains should be running between Toronto and Quebec, and from Toronto to Sudbury and beyond by the end of this year. Thus the process of welding the eastern units together has been proceeded with and the transcontinental idea takes on more definite shape.

Now the contracts to link up the lines between Sudbury and Port Arthur, and for another line to run westerly from Ottawa to connect with the Toronto-Port Arthur line have been awarded and work on both may be said to have fairly commenced. In the west construction men are already working on the remaining section of the transcontinental between Edmonton and Port Mann on the Fraser River. All of these contracts are to be completed by the close of 1913, and so much is the element of speed being considered that 9,000 men are engaged this winter on preliminary construction work in these two widely separated cities.

This brings us to the essential need of a proper terminal in Montreal City. In many interviews the various officials of the Canadian Northern have stated emphatically that the project in that eastern city would be finished by 1914. This means that the Montreal terminals will be ready for operation by the time through transcontinental trains will be running across the continent on Canadian Northern steel. The continuity of purpose marking the letting of all these contracts becomes at once apparent.

The terminal idea in Montreal was almost inspired. For a long time the company's engineers have been worrying over the securing of a plan in Montreal which would be in keeping with the dignity of a continent-wide line. The Mountain, to them was a very tangible obstruction, and it was felt that only under great difficulties would a suitable terminal be secured. Outside of Montreal surveys were run by the score, and it was only when desperation compelled that the idea of approaching the city from the Back River and tunneling under Mount Royal was proposed. To Mr. H. K. Wicksteed, the chief locating engineer of the Canadian Northern, will probably fall the honor of conceiving this radical venture. Colonel A. D. Davidson, Land Commissioner for the company, became enthusiastic over the project, and the possibility of the new subdivision back of the Mountain to the Back River was then born. This section of country would not only afford the company an ideal site for the location of terminal shops and yards, but it would also give to Montreal an opportunity for growth hitherto undreamed of.

Colonel Davidson, immediately the sanction of the executive was secured, began to plan the best methods of securing this territory and the necessary right of way in the city without exciting unduly the curiosity of the holder. The securing of this ten million dollars worth of property stands to-day as a remarkable achievement and is a striking testimonial to a man whose name is already writ large in land matters in Canada.

After all, the engineering difficulties will not be exceedingly great. The line will pass through the suburbs on a gentle rise of about forty feet to the mile, and from that entrance the tunnel will slope citywards at a gradient of about thirty-five feet to the mile, nosing out practically in the business district, for it will run at a considerable depth below what are now some of the principal streets of the city. The building of a palatial station and hotel are only incidents from the engineer's standpoint. The complete plan is not yet advanced sufficiently to allow a proper technical treatment in this paper, and will be considered in a later article.

PERSONAL.

Mr. W. D. Neil, recently of Calgary, has been appointed city manager of C.P.R. telegraphs at Winnipeg, Man.

Mr. J. C. Breithaupt has again been elected chairman of the Water Commission of Berlin, Ont., for the thirteenth term.

Mr. L. W. Rundlett, of St. Paul, Minn., has been appointed to the commissionership of Moose Jaw at a salary of $6,000 per year.

Dr. J. W. S. McCullough, provincial medical health officer, returned yesterday from New York, where he has been investigating the latest methods for water filtration and other matters.

Mr. Frank Swayze has been appointed general manager of the Niagara, Welland and Lake Erie Electric Railway. Previous to accepting this position Mr. Swayze held a position with the Niagara. St. Catharines and Toronto Electric Railway.

Mr. George A. Guess has been appointed to the chair of Metallurgy at Toronto University. Mr. Guess is a graduate of Queen's University, class 1894. His metallurgical experience covers some years spent with the Greene Cavanea Cooper Company, the largest concentrating and smelting concern in Mexico. He was also with the Tennes-

see Copper Company, a company in the States doing pyritic smelting, and with the Cerro de Pasco Mining Company of Peru, one of the largest metallurgical establishments in South America. All the large copper refineries and smelters of the United States have been visited by him.

Recent changes amongst Canadian Pacific Railway Telegraph officials include the following: W. J. Camp to be assistant manager of telegraphs, with headquarters at Montreal. F. J. Mahon of St. John, N.B., to be superintendent of the eastern division, with headquarters at Montreal. J. Fletcher of Vancouver to be superintendent of traffic, Montreal. J. F. Richardson to be superintendent of the British Columbia division, with headquarters at Vancouver. Wm. Godsoe of Halifax to be superintendent of Atlantic division, with headquarters at St. John. John Tait of Winnipeg to be assistant to the general superintendent at Winnipeg. John McMillan of Calgary to be superintendent of the Manitoba division, with headquarters at Winnipeg. R. W. Young to be superintendent of the Saskatchewan division, with headquarters at Moose Jaw. Donald Coons to be superintendent of the Alberta division, with headquarters at Calgary. Mr. Dan H. Bowen of London, Ont., to be assistant superintendent of Ontario.

OBITUARY.

The death occurred suddenly of Mr. G. H. Massey, a director and chief engineer of the Reid-Newfoundland Company, at his late residence, 4224 Dorchester Street, Westmount, Montreal. The deceased gentleman had been ailing for the past year. His death was due to heart failure.

Mr. Massey was born in Tullow, County Dublin, Ireland, came to Canada in 1871. He was engineer-in-charge of the Chaudiere bridge, Ottawa, the Canadian Pacific Railway bridge at Lachine, and also the Sault Ste. Marie bridge. He had been connected with the Reid-Newfoundland Company for the past 14 years. The deceased is survived by his widow and eight children.

THE ENGINEERS' CLUB OF MONTREAL.

The Engineers' Club of Montreal was organized and incorporated in 1903 by a number of Montreal engineers. While the by-laws were made broad enough to admit not only engineers and architects, but also others engaged in engineering work, the majority of the directors must be engineers. This qualification was included with the intention of preserving control in the hands of the engineers. The functions of the club are of a social nature. The charter members were about forty in number; there is now, however, a full membership of four hundred and fifty and a considerable number on the waiting list.

In 1905 the club purchased the Dow property on Beaver Hall Square, midway between up and down town. This is an ideal location for a club of such a character. On the property was located a fine residence, which, with a few additions and changes, was made into very homelike and comfortable quarters. The president of the club is Mr. H. H. Vaughan, and the secretary, Mr. Smith.

ANNUAL MEETING, PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

The Province of Quebec Association of Architects held their annual meeting in Quebec on January 13th. A dinner was held in the evening at Kent House, Montmorency Falls.

CANADIAN SOCIETY OF CIVIL ENGINEERS.

A meeting of the Mining Section was held on Thursday, 11th instant, at 8.15 p.m., in the society's rooms, 413 Dorchester Street Montreal.

A paper by Mr. James R. Pearson, managing director of the Asbestos and Asbestic Co., Ltd., was read by the author.

CANADIAN INSTITUTE MEETING.

The members of the Canadian Institute held their usual meeting at the library, 198 College Street, Toronto, January 13th, at 8 p.m. Professor Angus, of the Department of Mechanical Engineering, University of Toronto, gave an illustrated lecture on "Types of Steam Engines," including rotary and reciprocating.

MEETING OF WESTERN CANADA RAILWAY CLUB.

The monthly meeting of the Western Canada Railway Club was held in the Royal Alexandra Hotel, on Monday evening, the 8th inst., at 8.30 o'clock. There was a very interesting discussion on the paper read at the previous meeting on "High Speed Steel."

At the close of the discussion there was a short entertainment and New Year's reunion.

AMERICAN BOILER MANUFACTURERS' ASSOCIATION.

The 24th Annual Convention of the American Boiler Manufacturers' Association, together with its associate members, and the Supplymen's Association, will be held in New Orleans, La., March 12th, 13th, 14th and 15th, 1912, at which time some very important papers will be presented to the association and other important business of interest to all the boiler manufacturers in the United States and Canada, and supply houses dealing with the boiler and tank industry.

An extensive programme of entertainment has been arranged, and a large attendance of boiler manufacturers and supplymen from the United States and Canada are expected to be in attendance.

For further information relative to rates, hotel accommodation, etc., apply to F. B. Slocum, Secretary Supplymen's Association, of the American Boiler Manufacturers' Association, care of Continental Iron Works, Brooklyn, N.Y.

COMING MEETINGS.

THE ENGINEERS' CLUB OF TORONTO.—Wednesday, January 17th, 1912. 90 King Street West. Noonday address by Mr. Wyly Grier. Luncheon will be served promptly at 1.00 p.m., and members are requested to be in their seats before that time. R. B. Wolsey, Secretary.

THE CLEVELAND ENGINEERING SOCIETY.—January 23, 1912. Special Meeting, Chamber of Commerce Bldg., Cleveland, O. R. C. Beardsley, Hydraulic Engineer, will present an illustrated paper on "The Design and Construction of Dams," with special reference to recent failures. Secretary, F. W. Ballard.

THE CANADIAN SOCIETY OF CIVIL ENGINEERS.—Jan. 24. 25, 26, 1912, General meeting. 413 Dorchester St. West, Montreal. Prof. C. H. McLeod, Secretary.

CANADIAN FORESTRY ASSOCIATION.—February 7th and 8th, 1912. Forestry Convention Meetings held in the Railway Committee Room, Parliament Buildings, Ottawa. Secretary, Mr. James Lawler, Canadian Bldg., Ottawa.

CANADIAN LUMBERMEN'S ASSOCIATION.—February 6, 7 and 8, 1912. Annual Meeting to be held at the same time and place as the Canadian Forestry Association.

CANADIAN NATIONAL ASSOCIATION OF BUILDERS. — The Sixth Annual Convention will be held in Toronto, February 20, 1912.

ONTARIO GOOD ROADS ASSOCIATION.—Annual Convention to be held at Toronto, February 26, 27, 28. Secretary, J. E. Farewell, Whitby.

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, C. H. Rust; Secretary, Professor C. H. McLeod.

QUEBEC BRANCH—
Chairman, P. E. Parent; Secretary, S. S. Oliver. Meetings held twice a month at Room 40, City Hall.

TORONTO BRANCH—
96 King Street West, Toronto. Chairman, H. E. T. Haultain, Acting Secretary; E. A. James, 57 Adelaide Street East, Toronto. Meets last Thursday of the month at Engineers' Club.

MANITOBA BRANCH—
Secretary E. Brydone Jack. Meets every first and third Fridays of each month, October to April, in University of Manitoba, Winnipeg.

VANCOUVER BRANCH—
Chairman, Geo. H. Webster; Secretary, H. K. Dutcher, 319 Pender Street West, Vancouver. Meets in Engineering Department, University.

OTTAWA BRANCH—
Chairman, S. J. Chapleau, Ottawa; Secretary, H. Victor Brayley, N. T. Ry., Cory Bldg.

MUNICIPAL ASSOCIATIONS.

ONTARIO MUNICIPAL ASSOCIATION.—President, Chas. Hopewell, Mayor, Ottawa; Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

UNION OF ALBERTA MUNICIPALITIES.—President, H. H. Gaetz, Red Deer, Alta.; Secretary-Treasurer, John T. Hall, Medicine Hat, Alta.

THE UNION OF CANADIAN MUNICIPALITIES.—President, W. Sanford Evans, Mayor of Winnipeg; Hon. Secretary-Treasurer, W. D. Lighthall, K.C., Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer, J. W. McCready City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. E. McMahon, Warden, King's Co., Kentville, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secretary, Mr. Heal, Moose Jaw

CANADIAN TECHNICAL SOCIETIES.

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang; Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BUILDERS, CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Charles Kelly, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto. Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto.

CANADIAN ELECTRICAL ASSOCIATION.—President, N. W. Ryerson, Niagara Falls; Secretary, T. S. Young, Canadian Electrical News, Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, Thomas Southworth, Toronto; Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President. Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; J. Keillor, Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. Frank D. Adams, McGill University, Montreal; Secretary. H Mortimer-Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, T. A Starkey, M.B., D.P.H., Montreal. Secretary, F. C. Douglas, M.D., D,P.H. 51 Park Avenue, Montreal.

CANADIAN RAILWAY CLUB.—President, H. H. Vaughan; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, D. McDonald, Manager, Montreal Street Railway; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto, President, G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July, August.

DOMINION LAND SURVEYORS.—President, Thos. Fawcett, Niagara Falls; Secretary-Treasurer, A. W. Ashton, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, W. B. McPherson; Corresponding Secretary, A. McQueen.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President, Killaly Gamble; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian Members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain, and W. H. Miller, and Messrs. W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary, R. C. Harris, City Hall, Toronto.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C.B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, W. H. Pugsley, Richmond Hill, Ont.; Secretary, J. E. Farewell, Whitby.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, J. Whitson; Secretary, Killaly Gamble, 703 Temple Building, Toronto.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary J. E. Ganier, No. 5. Beaver Hall Square, Montreal.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, F. S. Baker, F.R.I.B.A., Toronto, Ont.; Hon. Secretary, Alcide Chausse, No. 5 Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Alfred T. de Lury, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Dr. A. McGill, Ottawa, President; Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, J. P. McRae; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Wm. Pierce, Calgary; Secretary-Treasurer, John T. Hall, Brandon, Man.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. Rosevear, 115 Phœnix Block, Winnipeg, Man. Second Monday, except June, July and August, at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc.
Printed forms for the purpose will be furnished upon application.

TENDERS PENDING.

In Addition to Those in this Issue.

Further information may be had from the issues of The Canadian Engineer referred to.

TENDERS.

Arcola, Sask.—The date for receiving tenders for addition to school building at Arcola, Sask., has been extended to Thursday, February 1st, 1912. Plans and specifications may be secured at the office of Storey and Van Egmond, Architecbts, Regina, Sask. Jas. R. Donaldson, Secretary S.D. 637, Arcola.

Brantford, Ont.—Tenders will be received by the Board of Education until January 27th, 1912, for the erection of a two-story schoolhouse on Chestnut Ave. Building will be comprised of basement, 84 x 112 feet, ten rooms, brick with reinforced concrete floors, concrete foundation, steam heating, electric lighting, etc., two dynamos (1½ h.p. and 5 h.p.), modern plumbing. Secretary, A. K. Bunnell, Brantford.

Calgary, Alta.—Tenders will be received until February 10th, 1912, for the supply of material and construction of a steel bridge, 30 feet wide, in three spans of 150 feet each, on concrete substructure, across the Bow River, within the city limits. (See advertisement on another page of this issue).

Chatham, Ont.—Tenders will be received until January 20th, 1912, for all trades in erection of a reinforced concrete brick and steel, fireproof building for the Chatham Gas and Electric Light Co., Ltd. Drawings, specifications, etc., can be seen at the offie of the architects, Jas. L. Wilson & Son, Chatham, Ontario.

Chesley, Ont.—Tenders will be received by the Department of Public Works, Ottawa, until January 31st, 1912, for the erection of a public building. Plans, specifications, etc., may be obtained at the office of Mr. Thos. A. Hastings, Clerk of Works, Postal Station F, Yonge St, Toronto; at the post-office, Chesley, Ont.; at the office of Foster & Clark, architects, Owen Sound, Ont., and at the office of R. C. Desrochers, Secretary, Department of Public Works, Ottawa.

Grandview, Man.—Wanted—For the Rural Municipality of Grand View, six (6) wheel scrapers, size two and one-half (2½). Tenders to be in by February 1st, 1912. Wm. Dickie, secretary-treasurer, Grandview, Man.

Halifax, N.S.—Tenders will be received until January 17th, 1912, for the installation of a new heating boiler in the city hall. Specifications, etc., may be obtained at the City Engineer's office. J. J. Hopewell, Clerk of Works.

Montreal, Que.—The city is contemplating an addition to the sewage farm at Back River, to cost $50,000. City Engineer, G. Janin.

Ottawa, Ont.—Tenders will be received until February 5th, 1912, for the erection of a wooden lighthouse tower at Lions Head, Lake Huron, Ont. Plans, etc., at the Department of Marine & Fisheries, Ottawa; at the post offices, at Lions Head, Owen Sound, Collingwood, and Wiarton.

Ottawa, Ont.—Tenders for the improvement of the public wharf at Petewawa, North Renfrew County, Ont., will be received at the Department of Public Works until January 31st, 1912. Plans, etc., obtained at the offices of J. G. Sing, Esq., District Engineer, Confederation Life Bldg., Toronto; on application to the Postmaster at Petewawa, Ont., and at the Department of Public Works, Ottawa.

Ottawa, Ont.—Tenders will be received until January 29th, 1912, for the supply of 650,000 tons of Bituminous Coal for the Intercolonial Railway, and 13,000 tons of Bituminous Coal for the Prince Edward Island Railway. Lois Lavoie, Purchasing Agent, Ottawa.

Regina, Sask.—Tenders marked "Tenders for Telephone Supplies," will be received until noon, Saturday, January 20th, 1912, at the office of D. C. McNab, Acting Deputy Minister, Department of Railways and Telephones, Regina.

Saskatoon, Sask.—Tenders will be received until February 16th, 1912, for the construction of approximately 125,750 square yards of pavements. Geo. T. Clark, City Engineer, Saskatoon. (Adv. in the Can. Eng.)

Saskatoon, Sask.—Tenders will be received until February 16th, 1912, for the construction of approximately 621,200 square feet of concrete walk and 100,950 lineal feet of curbing. City Commissioner, Geo. T. Clark, City Engineer, Saskatoon. (Adv. in the Can. Eng.)

Toronto, Ont.—Tenders will be received until January 31st, 1912, for the construction of concrete abutments and a steel bridge, 100-ft. clear span, and also for a reinforced concrete truss bridge, 50-ft. clear span, over the Burnt River, in the village of Haliburton, municipality of Dysart. Frank Barber, Civil Engineer.

Vancouver, B.C.—Tenders will be received by the undersigned up till January 27th, 1912, for the year's supply of the following articles: Cast-iron castings, cement, sand and gravel, sewer pipe and fittings, pig lead, lead pipe, galvanized pipe fittings, brass fittings, lubricating oils and greases, hardware, engineer's supplies. Specifications, blank tender forms and all particulars may be obtained from my office. James Stuart, City Purchasing Agent.

Victoria, B.C.—Tenders will be received until the 31st day of January, 1912, for the erection and completion of a large one-room frame school house at Johnston Road, in the Delta Electoral District, B.C.. Plans, etc., may be seen at the offices of the Rev. T. H. Wright, Secretary of the School Board, Cloverdale, B.C.; the Government Agent, New Westminster; and the office of J. E. Griffith, Public Works Engineer, Department of Public Works, Victoria, B.C.

Winnipeg, Man.—Tenders will be received until February 1st, 1912, for the manufacture and delivery f.o.b. Winnipeg of an electric vehicle. Further information may be obtained at the office of the General Manager City Light and Power Department, 54 King Street. M. Peterson, Secretary Board of Control Office, Winnipeg.

CONTRACTS AWARDED.

Lethbridge, Alta.—A new $20,000 hotel will be erected at Kipp, by Mr. J. V. Harrington, Kalispell, Montana.

Ottawa, Ont.—The contract for the construction of an extension to the protection pier at Gimli, Selkirk Co., Man., has been awarded to Messrs. Buchanan & Fraser, of Winnipeg, at $9,910.

Vancouver, B.C.—The British North America Construction Company, Bank of Ottawa Bldg., will begin shortly the construction work on a wharf, Carrall Street, for the Union S. S. Co., Carrall St. Cost, $70,000.

Vancouver, B.C.—Instructions have been given by the Grand Trunk Pacific to Foley, Welch & Stewart, that the main line from Tete Jaune Cache to Fort George must be finished by next fall. In consequence, sub-contracts have been awarded as follows:—H. E. Carleton & Company, Edmonton, 25 miles west from Cache; Messrs. Burns, Jordan & Company, of Spokane, 50 miles; Messrs. Sims Brothers & Keary, of St. Paul, 75 miles. There is still unlet to sub-contractors a gap of thirty miles.

Vancouver, B.C.—Messrs. Griffin & Wilson, Spokane, have received the sub-contract for the construction of the remaining thirty-five miles on the main line, from Tete Jaune Cache to Fort George, of the Grand Trunk Pacific. General contractors, Messrs. Foley, Welch & Stewart.

Vancouver, B.C.—The Portland Cement Construction Co. has let the contract for the immediate construction of a huge cement plant on Tod Inlet, Vancouver Island, to the McAlpine, Robertson Construction Company, Metropolitan Bldg. This concern is a branch of Robert McAlpine Sons, Glasgow and London. It is understood that the proposed plant will approximate very closely to $1,000,000.

Victoria, B.C.—The contract for the new plant of the Pacific Coast Cement Company on Saanich Arm has been let to the McAlpine, Robertson Construction Company, Vancouver, and work will be commenced immediately.

Winnipeg, Man.—The contract for the superstructure of the twelve-story office building for the Union Trust Company, to be erected on the northeast corner of Main and Lombard Streets, has been let to the George A. Fuller Company of Montreal, Chicago and Winnipeg.

Winnipeg, Man.—The contract for the superstructure of the new Osborne street bridge has been awarded to the Manitoba Bridge & Iron Works. Total cost of work about $116,461, will include cost of tearing down the present superstructure and re-erecting it over the Assiniboine River at Arlington Street. The whole work is to be completed within six months from the date of signing of contract. The Algoma Steel Bridge Company was the lowest tenderer, but as it asked for nine months to build the bridge, the tender was not accepted.

RAILWAYS—STEAM AND ELECTRIC.

Province of Alberta.—A report states that the Canadian Pacific have assumed complete control of the Alberta Central Railway, and will be responsible for all debts of that company. Work will be pushed ahead rapidly by the C.P.R. in the spring in order to have the line to the Brazeau coal fields finished next year, and it is also understood 100 miles of the line east of Red Deer will be built in 1913.

Province of British Columbia.—It is officially stated that the Canadian Pacific Railway will shortly operate its locomotives on its mountain division between Field and Kamloops B.C., by crude oil.

Calgary, Alta.—It is estimated that the yearly receipts from the Street Railway operations will amount to $391,000.00, of which nearly $120,000.00 will be profit.

Fredericton, N.B.—Sir Thomas Tait has acquired the control of the Fredericton and Grand Lake Coal and Railway Company. The plans for the development of the Grand Lake coal areas include the construction of the railway from Gibson to Minto, a distance of 30 miles, for the delivery of 10,000 tons of coal annually, which the C.P.R. will take. The construction work on the railway will be commenced early in the spring. At this session of the Dominion Parliament the Dominion subsidy for the road will be re-voted.

Montreal, P.Q.—Details of the proposed terminals of the Canadian Northern Railway include the following: A double tracked tunnel 3.3 miles in length from a point half a mile west of the C.P.R.'s Outremont yards to Lagauchetiere Street. An underground station on the Dorchester street site of the Joseph Estate. Elevated tracks from the tunnel mouth to the level of the present Brennan Street tracks. Elevated freight sheds between William and Wellington Streets, and Dalhousie and Nazareth Streets. Depth of the tunnel from 700 to 40 feet; elevation of the tracks from 16 to 20 feet. River front communication with the Moreau Street station and a spur line from the latter point to the proposed Dorchester Street terminal.

Ottawa, Ont.—The original plans of the Hudson Bay railway have been adopted, viz., from Pas Mission to Port Nelson. The contract was awarded to J. D. McArthur by the late government. It is understood that he will begin construction work at an early date.

Province of Ontario.—Conservtive members of the Ontario Legislature asked Premier Whitney yesterday to assist the Bruce Mines and Algoma Central Railway to extend its lines farther north.

Prince Rupert, B.C.—The Railway Commission have ordered the Grand Trunk Pacific to re-open Cameron Creek in a way to make it again navigable.

Quebec, P.Q. — The Ottawa, Abitibi and Hudson Bay Railway Company will apply to the Quebec Legislature for an Act authorizing it to construct and operate a line of railway within the Province of Quebec from a point near the City of Hull, Quebec, in a northwesterly direction, through the southwesterly part of the County of Wright; thence in a northwesterly direction through the County of Pontiac, via the Valley of the Coulonge River to Grand Lake Victoria; thence in a northwesterly direction to a point on the National Transcontinental Railway at or near Lake Mattagami; thence in a northerly by northwesterly direction to a point near James Bay.

Victoria, B.C.—The Victoria Harbor Railway Company will apply for an extension of time.

Vancouver, B.C.—At a largely attended mass meeting held at this city recently, a resolution was passed unanimously endorsing the project for a railway from Vancouver to the Peace River country. It was also decided to send a delegation to interview Provincial Premier McBride on the subject.

Vancouver, B.C.—The Great Northern Railway Company has been asking for bids for the dredging of the slips and approaches to its proposed piers on its 1,800 feet of Burrard Inlet waterfront in this city. The management was unsuccessful in its efforts to rent the Dominion Government dredge Mastodon for the purpose of doing this work and the contract may be awarded to a United States concern as there is only one privately-owned dredge in British Columbia waters, and it is declared to be of insufficient capacity to perform the improvement. It is estimated that about 150,000 cubic yards of sand, hardpan and rock will have to be excavated.

Winnipeg, Man.—Seven new locomotives have been delivered to the Grand Trunk Pacific within the past few days. The measurements are—length, 73 feet; weight, 200 tons; track power, 31,600 pounds; water capacity, 8,000 gallons.

York County, Ont.—Plans are developing for the extension of the Toronto Suburban Railway from the town of Weston to the town of Woodbridge. This distance is eight miles.

LIGHT, HEAT AND POWER.

Fredericton, N.B.—Repairs to the municipal power plant are a necessity, the pressing requirements are fifty new lamps at $24.00 each and a new armateur at $850.00. Owing to considerable trouble of late in the street lighting the Fredericton Gas Light Company are preparing a proposition to light the highways by gas.

Galt, Ont.—A committee has been appointed to look after the improvements in the lighting system of the library. Mr. Chas. Turnbull is a member of the Board.

Kingston, Ont.—On the advice of the Hon. Adam Beck the municipality will supply the Grand Trunk Railway with 500 electrical horsepower for use in their granite quarry. This supply is temporary.

For medium traffic and residential streets.

Dolarway Pavement

For permanent state highways, park roads, boulevards, etc.

IT IS PERMANENT BECAUSE IT IS CONCRETE.

What is Dolarway Pavement?

FIVE to six inches of Portland Cement Concrete provided with the necessary expansion joints. The surface is then treated with our adhesive Dolarway Bitumen and with coarse sand or fine gravel or screenings. This seals the concrete, prevents cracking and chipping, and produces a wearing surface which is clean, noiseless, resilient and similar in appearance to other forms of bituminous pavement.

What Does It Cost?

You can figure out what the concrete will cost per square yard in your vicinity. Add to this from 25 cents to 35 cents per square yard which represents the cost of the bitumen sand and labor, and the small royalty charged by our Company.

Great Economy Possible.

Sealing the surface of the concrete by our method makes it possible, for the first time, to construct a pavement or highway having a concrete base and a noiseless bituminated wearing surface at from 50 cents to $1.00 per square yard less than the cost of any other permanent pavement.

Low Cost of Maintenance

The Dolarway Pavement can be resurfaced when necessary at a price of from ten to twenty cents per square yard, thus making it as good as new and prolonging its life indefinitely.

Medium Traffic and Residential Streets.

Permanent, noiseless and dustless. Not affected by motor traffic. Ideal for the smaller cities, as no expensive machinery is required.

For Good Roads.

Wherever there is gravel or stone (hard or soft), you can build Dolarway Pavement cheaper than any other permanent roadway.

Notice to Contractors.

Correspondence solicited from responsible contractors to represent Dolarway Pavement for unallotted territory.

DOLARWAY PAVING COMPANY

95 Liberty Street,
NEW YORK CITY.

510 Title and Trust Building,
CHICAGO.

One of the methods of applying and spreading Dolarway Bitumen on Concrete Base.

Finished Dolarway Pavement.

Lakefield, Ont.—The Hydro-Electric by-law having carried, the town proposes to spend $8,000 on a distributing plant and sub-station. Mr. E. A. Tanner, reeve.

Quebec, P.Q.—The Saint Maurice Hydraulic Company will apply to the Legislature of Quebec for an act to construct storage and regulating dams on the Saint Maurice River and its tributaries.

Vancouver, B.C.—An addition unit of 10,500 h.p. is now running at the plant of the B.C. Electric Railway Company. The output of the plant at present is 43,500 h.p. To accommodate the new unit a stone and concrete fireproof extension of 60 feet was made to the power house on the shore of the North Arm. The unit represents an outlay of approximately $250,000.

SEWAGE AND WATER.

Calgary, Alta.—The report of the city engineer, Mr. Childs, calls for an expenditure of $405,000.00. He recommends a filtration system:

Costing	$200,000
New intake costing	90,000
Enlargement of reservoir	85,000
Sedimentation tanks	30,000

Edmonton, Alta.—The city commissioners have decided to construct two new intakes and a well on the river bank; also to abandon the present intake. The city engineer, Mr. A. J. Latornell, has been instructed to prepare plans, etc. Ice has seriously damaged the present intake.

Galt, Ont.—Hydro-electric energy will be used to operate the pumps at the municipal waterworks. P. W. Sothmann, of the Hydro-Electric Commission, has suggested the use of a 250 K.V.A. synchronous motor running at 2,200 volts pressure as the most satisfactory method of taking care of the power factor.

Galt, Ont.—The town council has between fifty and sixty men working, mostly on sewers, at the present time and it is likely that this number will shortly be increased to one hundred.

Guelph, Ont.—The by-law providing for the election of Sewerage and Public Works Commissioners was given its third reading and passed by the council.

Ingersoll, Ont.—The late council passed a by-law to purchase the waterworks for the sum of $125,000.00.

Montreal, P.Q.—The bursting of a water main on St. Nicholas Street caused serious loss to several tenants of the Coristine building. The damages are estimated at about $2,000.

New Westminster, B.C.—The Municipal Construction Company have presented an account to the council for $3,000.00 for repairing 700 leaks in the water mains leading from Lake Coquitlam. This firm has the contract for laying the main. The pipe was purchased by the city council in 1909, and the contract let in 1910. The fault was that the collars used were of a defective design and that they were in most cases too large. The contractors had to insert a flattened wire before they could caulk the joints. 150 leaks are due to loose rivets. A strict investigation will be held.

Toronto, Ont.—The Works Committee have recommended the municipal council that a sewer be reconstructed on Sorauren Ave. The cost of the work will be about $44,077 to be assessed against the property benefited to the extent of $11,148, and against the city to the extent of $32,929.

Toronto, Ont.—A new pumping engine with a capacity of 15,000,000 gallons a day, will likely be included in the estimates of the City Engineer.

Victoria, B.C.—The municipal council have passed a resolution in favor of increasing the sewage handling facilities.

DREDGING MACHINERY.

One of our subscribers would like to be put in touch with firms who make dredges suitable for drainage work of from five hundred thousand to one million cubic yards. The widths would vary from forty to one hundred feet. He says a dipper dredge would hardly be suitable, owing to the distance the earth has to be moved to clear the banks of the cut. Any information on this subject will be appreciated by the Service Bureau, Canadian Engineer.

BUILDING.

Baden, Ont.—The Baden Board of Trade are endeavoring to secure a Carnegie library. Mr. Gideon Bechtel is chairman of the Board. (Baden is near Galt.)

Brantford, Ont.—The Cockshutt Plow Company have purchased the plant and buildings of the Brantford Carriage Company. Large additions to the buildings are among the plans of the Cockshutt Company.

Fort William, Ont.—A new hotel for the Grand Trunk Pacific, to cost $750,000.00, is among the plans of building operations for 1913.

Fort William, Ont.—Work in connection with the erection of the addition to the G.T.P. elevator has commenced. The John S. Metcalf Contracting Company, Montreal, secured the contract. The sub contracts have been awarded to an Omaha, Nebraska, firm.

Frank, Alta.—The Keystone Portland Cement Company, capitalized at $600,000.00, will begin building operations at an early date. The plans call for the employment of 100 men and a daily output of 1,000 barrels. The president is Mr. A. Muller, of Frank and Paris, general manager of the Canadian Coal Consolidated Co. of Frank.

Galt, Ont.—The Katie Foundry will erect new premises in Galt. A site has been secured on the river front. The main building will be of brick and concrete, seventy feet square and an annex, 70 × 120 feet, will be built along the full length of the building. This will be a two storey brick structure. The latest appliances, including two five ton electric cranes, will be installed and modern methods of handling and storing the raw materials will be used. Mr. J. R. Ferguson, of Galt, is president of this foundry.

Province of Ontario.—The estimates of the Dominion Government include the erection of the following public buildings:—

Athens—Public building	$18,000
Aurora—Public building	6,000
Aylmer—Public building	15,000
Barrie—Public building, improvements of grounds	1,000
Bracebridge—Public building	18,000
Campbellford—Public building	15,000
Dominion—Public building, renewals, repairs, improvements, etc.	20,000
Dresden—Public building	12,000
Dundas—Public building	31,000
Durham—Public building	10,000
Elora—Public building	8,000
Elmira—Public building	5,000
Essex—Post-office	20,000
Fergus—Public building	8,000
Fort Frances—Public building	15,000
Fort William—Public building enlargement	11,000
Gananoque—Post-office	25,000
Goderich—Public building, addition	5,000
Hamilton—Examining warehouse, additions and improvements	10,000
Hanover—Public building	10,000
Harriston—Public building	19,000
Kemptville—Public building	10,000
Kingston—Post-office, addition to building and alterations	50,000
Kingston—Royal Military College, additional dormitory accommodation for cadets	75,000
Kingston—Customs House renewals and repairs to building	1,300
Kingsville—Public building	15,000

Kerr Turbo-Generators

FOR SMALL LIGHTING PLANTS

The Kerr Turbine is peculiarly suited to generator driving and our sets are made in suitable sizes to fill all requirements up to 500 kw. alternating and 350 kw. direct current. The operation is economical throughout a wide range of initial steam pressures, the steam economy is improved by superheat, and any exhaust conditions are permissible. When operating non-condensing, the steam consumption compares favorably with that of a high speed engine of the same capacity, while in condensing plants the economy at full loads equals that of the best compound engine and at fractional loads is much better.

A Kerr Turbo-Generator for lighting or small power or both is extremely profitable in any plant having power boilers, since the freedom of the turbine exhaust from oil makes reuse of the exhaust inexpensive and safe for boiler feeding or any other purpose where clean low pressure steam is desirable. See Bulletin No. 22.

Todd Inlet, B.C. — The Portland Cement Contraction Company has commenced operations on the erection of a million-dollar plant at Todd Inlet, Vancouver Island.

Toronto, Ont.—The City Engineer, Mr. C. H. Rust, has been instructed to find some one willing to remove a large wooden bridge on Toronto Island. The party will have the material for his trouble. The bridge is entirely wood construction and in a fair state of preservation.

Toronto, Ont.—The $600,000 appropriation passed by the Board of Control for the supplementary building estimates include:

New Schools.

Clinton Street	$ 75,000
St. Clair Avenue	55,000
Dovercourt district	60,000
Western Avenue district	60,000
Morley Avenue	115,000
Total	$365,000

Enlargements.

Malvern High School	$ 60,000
Brock Avenue or Kent	75,000
Alterations	55,000
Purchase of sites	45,000

Vancouver, B.C.—A report states that a ten-story steel and concrete office building will be erected for Messrs. Henry Birk & Sons, of Montreal, P.Q. The total investment will be approximately $1,000,000, of which $450,000 is for land value.

Victoria, B.C.—The municipal board of health have impressed the newly formed council with the necessity of erecting an isolation hospital at an early date.

Woodstock, Ont.—The mayor recommended the council to prepare a measure for the erection of a new city hall.

ROADS AND PAVEMENTS.

Aurora, Ont.—Sir William Mulock has made an offer to the town of Aurora to contribute $3,000 towards the expense of making Yonge Street in the town limits a first-class roadway, or as good as that planned by the "good roads commission." Aurora is not in the good roads zone.

Galt, Ont.—The Board of Works has been instructed to call for tenders for a new steam road roller.

Province of Quebec.—The provincial Minister of Agriculture announces that $300,000.00 will be spent during 1912 for road improvements within the province.

Welland, Ont.—The Welland Town Council held a meeting in the Town Hall on Friday evening, the 12th inst., when they instructed the town engineer to prepare at once plans for this year's pavement, said plans to be ready in four weeks, when tenders would be called for, to allow the work being commenced not later than 1st of May. Pavements are to be laid on East Main Street from Grand Trunk Station to Canal Bridge; on South Main Street from Canal Bridge to Michigan Central Station; and on West Main Street from Canal Bridge to Niagara, St. Catharines and Toronto Railway Station. Tenders will be called for three or four different kinds of pavements, and will cover an area of 40,500 square yards. It is further expected that the residents on Hellems Avenue, Division Street, Merritt Street, part of Shotwell and part of Elgin Street will petition at an early date for pavements.

BRIDGES, DOCKS, ETC.

Province of Ontario. — The estimates of the Dominion Government include the following dock expenses for this province. The appropriation for rivers and harbors for Ontario aggregates $1,122,275, of which $547,175 is to be revoted. The details are as follows:—

Brockville—Extension of Tunnel Bay dock	$ 9,000
Cobourg—To repair and reconstruct superstructure on east pier at north end	10,000
Detroit River—Protection of east bank in the Township of Malden, to complete	2,500
French River, Lake Nipissing—Regulating works at outlets	11,200
Goderich—Harbor improvements	150,000
Gravenhurst—Wharf on Lake Muskoka	9,000
Haileybury—Harbor improvements	10,500
Hamilton—Harbor improvements	54,000
Harbors, rivers and bridges, general repairs and improvements	50,000
Huntsville—Wharf extension	1,750
Kincardine—Extension to pier and dredgnig	25,000
Kincardine—Repairs to pier	1,000
Kingston—Royal Military College, renewing wharfs	16,000
Kingston—Harbor improvements	50,000
Leamington—Repairs to wharf	1,000
Lakeport—Reconstruction of wharf	1,600
Lion's Head—Dock extension and harbor improvements	6,000
Meaford—Closing of eastern entrance and removal of L of inner check water	34,000
Montreal River—Removal of boulders in flat rapids	3,500
Montreal River—Improvements above Latchford	35,000
New Liskeard—Harbor improvements	18,000
North Bay—Breakwater	16,000
Owen Sound—Harbor improvements	36,200
Owen Sound—Harbor improvements to repair sheet piling along west side of harbor	3,500
Peterboro—Wharf	13,500
Pembroke—Repairs to wharf and approach	2,500
Port Bruce—Extension of west pier and repairs to east and west piers	1,800
Port Burwell—Improvements to harbor works	50,000
Port Colborne—Urgent repairs to east breakwater	17,000
Port Hope—Repairs to and improvements to piers	9,000
Port Stanley—Harbor improvements	100,000
Providence Bay, Manitoulin Island—Extension wharf	16,500
River St. Lawrence—Improvement of Canadian channel between Kingston and Brockville	60,000
River Thames—Removal of obstructions, etc.	4,000
Rousseau—Wharf repairs	800
Saugeen River—Repairs to north and south piers	1,000
Sault Ste. Marie—Improvements to old Plummer Wharf and approach	32,000
Sault Ste. Marie—Wharf addition to return on west side	8,000
Sturgeons Falls—Completion of dock	1,000
Southampton—Harbor improvements	1,750
Toronto—Harbor improvements	195,000
Windsor—Landing dock and improvements	50,000

TRADE ENQUIRIES.

The following were among the inquiries relating to Canadian trade received at the office of the High Commissioner for Canada, 17 Victoria Street, London, S.W., during the week ending January 1st, 1912:—

A Liverpool firm who are large buyers of dried and pickled fish are open to hear from Canadian shippers.

A Welsh firm interested in a process for utilizing sawdust are desirous of getting into touch with Canadian lumber manufacturers.

Seven Great Money-Saving Packings

Engineers and machinists throughout the Dominion are saving thousands of dollars in *time alone* by using Goodyear Packings—*short cuts* to *RESULTS.*

Installed quickest and most easily. *Outlast* all others. Recognized by all who *know packings*, as the highest standard of excellence. Use one of these great

GOODYEAR Packings

Magnet Sheet Packing

Meets *every requirement*—Boiler Room or Machine Shop. Made of special compound that *resists heat*, hence the *only* packing thoroughly adapted for high pressure uses. Makes tight joint under air or hot or cold water pressure, *Unaffected* by oil, liquor, ammonia, or alkali. Retains elasticity.

Magnet Gasket Tubing

For high pressure. Like Magnet Sheet Packing this tubing is unaffected by heat, makes tight joint, can't *blow out.* Cut any length to fit any size manhole, hand-hole, plate or pipe flange. Put up in convenient boxes with rubber core and tape.

Round Duck Packing

Fine quality cotton duck with round core. Used like Hydraulic Packing, *only for lower pressure.*

Hydraulic Packing

Best Packing for pump cylinders, inside-packed plungers pumping hot or cold water, and hydraulic elevators. Unexcelled for boiling water and high pressure hydraulic work.

Cloth Insertion Packing

For cold and warm water pipes. Unexcelled in pliability, smoothness of finish and strength of cloth insertion. Made of heavier fabric than any other similar packing on the market.

Square Duck Packing

Good quality cotton duck and friction to stand cold water. Cut accurately into squares.

Square Duck With Rubber Back

Specially adapted for elevator use. Made of superior cotton duck, gum back Makes packing tight, practically no friction. Gives many times service of other packings of same nature.

Valves

Unaffected by oil. Used in hundreds of industrial plants. Specially made to meet specific conditions.

Goodyear Packing, Belting, Hose and other rubber sundries enable you to capitalize the brains and experience of the world's greatest rubber goods experts—the knowledge and skill that underlies our reputation as well as that of the Goodyear Tire & Rubber Company, Akron, Ohio, the best known plant of its kind in the United States.

A London firm of iron, steel and metal merchants desire to appoint an agent at Calgary.

A London firm manufacturing an extract of coffee desire to open up business in Western Canada.

A Staffordshire manufacturer of fancy earthenware is desirous of appointing Canadian representatives.

A London produce importer would like to hear from Canadian buyers of tomato puree.

A German commission house wish to get into touch with some good furniture dealers in Canada open to handle Russian made bentwood furniture manufactured in the Austrian style.

A Montreal firm of lubricating oil manufacturers make inquiry for the names of United Kingdom refiners of rape oil.

A Toronto firm desire to get into touch with a United Kingdom firm able to supply large regular shipments of castor oil.

A Winnipeg firm desire to get into communication with manufacturers of twist drill bits, such as are used by woodworkers, blacksmiths, etc.

A real estate agent stated to have been established for many years in British Columbia wishes to represent a first-class fire insurance company.

A Toronto firm desire to get into touch with a United Kingdom manufacturer of gasoline road rollers.

A Canadian firm desire to take up the representation of a United Kingdom manufacturer of whiting.

A firm at Toronto are desirous of obtaining the representation of English china clay merchants.

A firm in the Province of Ontario are contemplating the export of maple and basswood last blocks, and would like to hear from United Kingdom users or manufacturers of shoe lasts open to purchase supplies.

A Toronto firm wish to secure the representation of United Kingdom chemical manufacturers, and have an immediate demand for large quantities of sulphur and borax.

A Montreal correspondent is open to take up United Kingdom agencies for inks, glues, dye-stuffs, and other lines excepting dry goods.

Inquiry is made by a Toronto firm for the names of United Kingdom manufacturers of fire engines.

A Canadian firm are open to import Portland cement, and would like to hear from United Kingdom firms open to do Canadian trade.

From the branch for City Trade Inquiries, 73 Basinghall Street, S.E.:—

A London manufacturing firm seeks supplies of special wood handles as used in the production of baby carriages, and would be glad to receive quotations from Canadian manufacturers.

A Yorkshire company manufacturing specialties in wood stains and preservatives, and also paints and enamels, ask to be placed in touch with a first-class Canadian firm who would be prepared to act as their representative.

CURRENT NEWS.

Berlin, Ont.—A society taking the name of the Great Waterways Union of Canada has been organized in this municipality. The object is for the purpose of developing the inland waterways of Canada, and the securing of navigation for ocean vessels on the Great Lakes via St. Lawrence and Welland canals route. The Mayors and Presidents of the Boards of Trade of the towns and cities of Canada will constitute the general committee, and will be invited to signify their intention of acceptance.

Calgary, Alta.—Mayor Mitchell is at present investigating the fire alarm system of some eastern Canadian cities. It is highly probable that a system costing $35,000 to $40,000 will be installed at an early date.

Sydney, C.B., N.S.—The output figures of the Dominion Iron & Steel Company's plant for December are as follows:

Coke	47,121 tons
Pig Iron	30,062 tons
Steel Ingots lb.	30,241 tons
Blooms	24,551 tons
Rails	5,014 tons
Rods	7,509 tons
Sulphate Ammonia	445 tons

BUSINESS.

Hamilton, Ont.—Fire considerably damaged the plant of the Dominion Vinegar Company. The loss is estimated at $20,000.00.

Regina, Alta.—$180,000.00 was the estimated loss to the McCarthy Supply Company when their departmental store was badly damaged by fire.

Moosejaw, Sask.—The Moosejaw Machine Works are now under the control of Saskatchewan Bridge and Iron Company.

Indian Head, Sask.—Damage amounting to $20,000 was caused by fire to the experimental farm buildings at this point.

PERSONAL.

Mr. E. Cousins has been appointed to the position of engineer of the Civic Harbor Commission of Toronto, Ont.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA.

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from The Canadian Engineer for small fee.

ORDER NO. 15754.

Whereas many general complaints and petitions have been made to the Board against the existing freight rates charged by the railway companies operating in Canada west of Lake Superior, and the Board had been delaying the consideration thereof until the final determination of the Regina Rate Case;

And whereas the Supreme Court of Canada, on the 6th day of December, ultimo, dismissed the appeal of the Canadian Pacific and Canadian Northern Railway Companies from the Order of the Board No. 12520, dated the 10th day of December, 1910, in the matter of the application of the city of Regina (above referred to), requiring the discrimination in favor of points in the Province of Manitoba, and against points in the Provinces of Saskatchewan and Alberta, to be removed by reducing the class freight rates from Port Arthur and Fort William, and points east thereof, to the said points in Saskatchewan and Alberta, and the said dismissal having left the Board free to undertake a wider investigation;

And whereas the tolls of the railway companies operating in the Province of British Columbia are already the subject of enquiry by the Board, upon the complaints of the Vancouver Board of Trade and the United Farmers of Alberta;

And whereas the Board is empowered by the Act, upon its own motion, to hear and determine any matter or thing which, under the Act, it might enquire into, hear and determine upon application or complaint;

Therefore it is declared to be advisable that:

(1) A general enquiry be at once undertaken by the Board into all freight tolls in effect in the Provinces of Manitoba, Saskatchewan and Alberta, and in the Province of Ontario, west of and including Port Arthur, with the view that, in the event of its being determined that the said tolls, or any of them, are excessive, the same shall be reduced as the Board may determine.

(2) A sitting of the Board will be held at the city of Ottawa on Tuesday, the 13th day of February, 1912, at ten a.m., to consider the procedure upon the said enquiry and give directions with reference thereto.

NOTE:—The Board is applying to the Minister of Justice to appoint counsel to represent the public upon the said enquiry.

15696—December 27—Authorizing C.P.R. to open for carriage of traffic its (portion of) Weyburn-Lethbridge Line from mileage 52.2 to mileage 75.85, a distance of 23.65 miles, Ogama to Viceroy.

15697—December 28—Authorizing Esquimalt & Nanaimo Railway to use and operate bridges at mileages 14.0, 54.4, 131.7 and 132.3.

15698—December 26—Relieving C.P.R. from further protection at crossing mileage 45.1 from Place Viger Station.

15699—December 29—Approving revised location of C.P.R. Swift Current to Brooks Branch at mileage 0 to 35.32, Saskatchewan.

15700—December 28—Authorizing C.P.R. to construct its Wilkie Northwesterly Branch across highway at mileage 7.64, Saskatchewan.

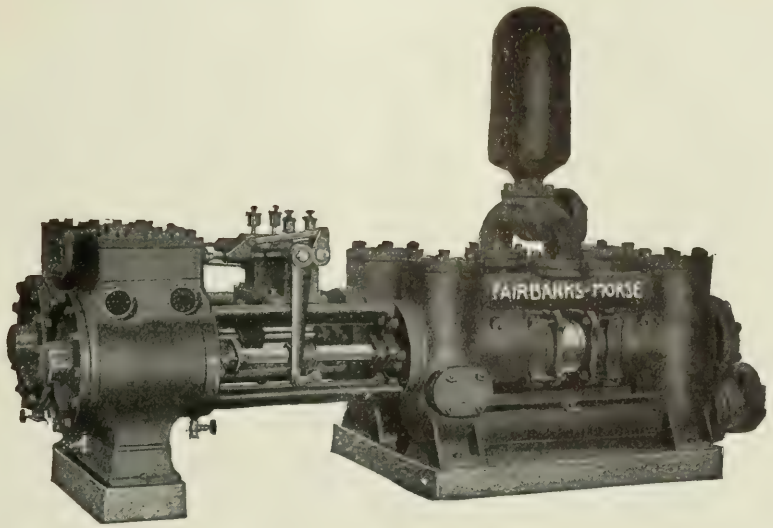
15701-02—December 29—Authorizing C. N. O. Ry. to cross three highways in Twp. of Trafalgar, County of Halton, Ontario, and highway in Twp. of Nelson, County of Halton, Ontario.

15703—December 27—Authorizing C.N.R. to construct spur in city of Saskatoon, Sask., north of Seventeenth Street.

15704—December 28—Authorizing G.T.R. to operate its trains through junction at Alford Jct., Ont., without stopping.

15705—December 28—Authorizing G.T.R. to construct spur for National Brick Co., Ltd., at St. Constant, Que.

15706—December 28—Approving certain changes and alteration in G.T.P. Ry.'s revised location in District of North Alberta, Alta.



PUMPS

The superior excellence and splendid results shown by

"FAIRBANKS-MORSE"

pumping machinery are largely due to the fact that for many years we have manufactured Hydraulic Machinery of all descriptions. We are therefore able to build pumps which are properly designed and adapted to every-day use. This is of the greatest importance in a first-class pump, for the usefulness of an engine may be lost if the pumping machine is badly designed.

You will get all these important features when you purchase a "FAIRBANKS-MORSE" pump.

Let us solve your pump problems.

THE CANADIAN FAIRBANKS-MORSE CO. Limited

Fairbanks Standard Scales — Fairbanks-Morse Gas Engines.

15707—December 28—Authorizing C.N.O. Ry. to cross seven highways in Twps. of Nelson and Trafalgar, Counties of Peel and Halton, Ont.

15708—December 28—Approving location of C.P.R. Wilkie to Anglia Branch at mileage 24.90 to mileage 40.66 and to cross and divert fourteen highways, mileage 25.55 to 40.66, Saskatchewan.

15709—December 29—Authorizing C.P.R. to construct two spur lines for Imperial Oil Co., Ltd., near Alexander Avenue, Winnipeg, Man.

15710—December 29—Authorizing C.N.O. Ry. to cross three highways in Twp. of Nelson, County of Halton, Ont.

15711—December 30—Authorizing C.P.R. to reconstruct bridge No. 15.3 over Isaac Creek, B.C., Division, Arrow Lake Subdivision, rescinding Order 15681 of December 26, 1911.

15712—December 29—Authorizing C.P.R. to cross with its Estevan-Forward Branch thirty-nine highways in Saskatchewan.

15713—December 30—Approving revised location of C.N.O. Ry. near Nipigon, Ont., mileage 497.16 to 498 from Sudbury Jct.

15714—December 30—Authorizing C.N.O. Ry. to cross eight highways in Twp. of Toronto, County of Peel, Ont.

15715—December 19—Authorizing G.T.R. to take certain lands in city of Kingston for enlarged railway facilities.

15716—December 27—Suspending G.T.P. Local and Joint Passenger Tariff C.R.C. No. 129 relating to "baggage of excess size" until all parties can be heard.

15717—December 19—Approving C.P.R. revision of grade between St. Martin's Jct. and Ste. Therese, and to construct across with double track six highways.

15718—December 15—Amending Order 7112, May 18, 1909, re London Street bridge, Windsor, Ont., and Michigan Central Railroad Co., substituting another plan and providing that new bridge be built during 1912.

15719—January 2—Naming William M. Tisdale, attorney at law, Redlands, Cal., and J. P. Hartman, attorney at law, Seattle, Wash., as commissioners for examination of witnesses in Dawson Board of Trade vs. White Pass & Yukon Route Railways Rate Case.

15720—November 27—Dismissing application of Jos. Hoolahan, of Ste. Agatha des Monts, re rates charged on perishable shipments by C.P.R.

15721—December 30—Authorizing G.T.P. Ry. to construct transfer track to connect with C.N.R. at Portage la Prairie, Man.

15722—January 2—Authorizing Midland Railway Co. of Canada (G.N. Ry.) to operate crossing for construction purposes only until 10th March, 1912, at connection with C.N.R. and crossing of G.T.P. Parish of St. Boniface, Man.

15723—December 30—Authorizing C.N.O. Ry. to construct over Rideau Canal and Rideau River by bridge at Smith's Falls.

15724—November 21—Disallowing tariffs of G.T.R., C.P.R., C.N.O., C.N.Q.R., Quebec, Montreal & Southern, Central Vermont, Ottawa & New York, Central Ontario, 1000 Islands, and Lotbiniere & Megantic, and N.Y.C. & H.R.R. and Rutland Railroads increasing rates on hay and straw from Ontario and Quebec to eastern United States points. These rates were postponed by Order 15080, October 12, 1911, until January 1, 1912, and are now disallowed.

15725—December 16—Directing C.P.R. to, before May 1, 1912, give Samuel Plunkett, of Twp. of Vaughan, County of York, Ont., as good grade over new crossing as over old one before track was elevated.

15726—January 3—Extending until February 15, 1912, time for filing tariffs by G.N.R. on fertilizers for W. H. Haight, Piper's Siding, B.C., from Vancouver and New Westminster.

15727—December 19—Directing G.T.P. Ry. to construct station on Lot 882, Group 1, Cassiar District, B.C., and restraining said company from locating station on Lot 851, Group 1, Cassiar District, B.C. Application Robert Kelly, of Vancouver, B.C.

15728—January 3—Authorizing C.N.O. Ry. to cross public road between southeast and southwest parts of Lot 15, Con. 1, Twp. of Toronto, County of Peel, Ont.

15729—January 2—Authorizing C.P.R. to construct spur for Shawinigan Water & Power Co., Parish of Notre Dame du Mont Carmel, County of Champlain, Que.

15730—January 2—Refusing application of G.T.P. Ry. for approval of location of its Prince Rupert Westerly Line mileage 6.60 to 3.23, Range 5, Coast District, Province of British Columbia.

15731—January 3—Directing C.P.R. to, before May 1, 1912, provide a suitable farm crossing for James Connelly, of Macleod, Alta.

15732—January 3—Directing C.P.R. to, before June 1, construct cattle pass for James Smith, Wolffton, Sask.

15733—January 4—Authorizing C.P.R. to operate siding to Union Stock Yards Co., at Toronto, Ont.

15734—January 3—Amending Order 15580, December 11, 1911, costs of protection to be paid, one-third by G.T.R. and two-thirds by T., H. & B. Ry.

15735—January 2—Directing G.T.P. Ry. to remove suffcient rock fill at Cameron Bay, Prince Rupert, B.C., and to file with Board before February 15, 1912, plan showing location of opening and depth of girders for carrying track, etc. Complaint of firms of Prince Rupert, B.C., re obstruction caused navigation at Cameron Bay.

15736-37—January 5—Approving location of C.N.O. Ry. (Montreal-Port Arthur Line) through Twps. of Widdifield, Commanda, Beaucage and Pedley, District of Nipissing, mileage 346.37 to 366 from Montreal; and through Twp. of Capreol, same District, mileage 0 to 71.81 from Capreol Junction.

15738—January 4—Authorizing C.P.R. to construct two spurs to premises of Port Arthur Wagon Co., Ltd., Port Arthur, Ont.

15739—January 3—Authorizing C.N.O. Ry. to construct branch line from Oshawa station to town of Oshawa, mileage 0 to 3.95, to connect with tracks of Toronto Eastern Ry. Co.

15740—January 4—15741—January 3—15742—January 2—Authorizing C.P.R. to construct spur to premises of Strome Milling and Grain Co., Ltd., at Strome, Alta., and into premises of Swift Canadian Co., Ltd., Winnipeg, Man., also for Messrs. E. Julian Co., Ltd., city of Quebec.

15743—January 4—Authorizing C.P.R. to reconstruct bridge 63.8, Brandon Subdivision, Manitoba Division.

15744—January 3—Relieving C.P.R. from further protection at crossing in village of Campbellville, Ont.

15745—January 3—Authorizing T.H. & B. Ry. to construct spur for Armstrong Supply Co., Ltd., Hamilton, Ont.

15746—January 3—Authorizing G.T.R. to construct spur for Messrs. Schell Bros. and Blow on Lot 49, 1st Con., Twp. of North Cayuga, County of Haldimand, Ont.

15747—January 3—Relieving G.T.R. from further protection at crossing 1½ miles east of Glencoe, Ont.

The Canadian Engineer

An Engineering Weekly

THE WATERPROOFING OF SEWERS

The subject of ground water infiltration into sewers is an exceedingly important one where it is necessary to pump and purify a large part of the effluent. A topical discussion of the subject is published in the proceedings of the National Association of Cement Users, for 1911, from which the following is abstracted.

Mr. George T. Hammond, designing engineer of the Brooklyn Bureau of Sewers, presented the following data:

New Orleans, La.—The plan provided for the removal of 0.003 cu. ft. per sec. per acre of ground water, or 1,250,000 gals. per sq. mile per day. In 1909 one sewage pumping station had an average dry weather discharge of 20,000,000 gals per day, of which "probably 15,000,000 gals. is ground water, which is being absorbed continuously from the soil of the city, lowering its moisture line in the soil and vastly improving its sanitary condition."

The sewers of New Orleans were constructed with great care, on the separate system, and Mr. Hammond considers the system one of the finest in the world. It is so located that the pumping of ground water is a distinct advantage to the city. Therefore, no waterproofing was undertaken, but the joints were all made as tight, and the work was constructed as water-tight, as such work can be made without special provision for waterproofing. The surface of the city is lower than the surface of the Mississippi River, except along the levees. However, the result well illustrates the freedom with which ground water enters well constructed sewers that have not been specially waterproofed.

The pipe sewers, from the smallest size up to 36 ins. in diameter, are of the very best quality of vitrified stoneware pipe. The main sewers are principally of brick, although there are also several miles of concrete sewer of sizes from 3 ft. 9 in. to 5 ft. 9 in. in diameter.

Brooklyn, N.Y.—The portions of the system in low ground admit considerable ground water. In one section of the city which contains about 200,000 population, and in which the dry weather flow is pumped and treated, from 5 to 20 per cent. of the flow, in accordance with the season, is estimated to be ground water. The total dry flow varies from 15,000,000 to 20,000,000 gals. per day. The system consists of brick main sewers, and of vitrified and concrete pipe collectors. The two kinds of pipe are used in about equal quantities. The maintenance cost per mile per year is about equal on each kind of pipe and is very low. Maintenance cost of brick sewers per mile is about four times as great. At Coney Island the leakage into sewers ranges from 20 to 50 per cent. of the flow, all of which has to be pumped. The Sewer Bureau is relaying much of this leaky system with sewers having carefully waterproofed joints.

Reading, Pa.—The water supply is 127 gals. per capita. The sewage is 163 gals. per capita. The infiltration of ground water amounts to 5,172 gals. per mile per day. The system is practically new and is constructed of vitrified pipe, and brick and concrete mains.

Providence, R.I.—The amount of sewage pumped in 1905 was as follows: Daily average for the year, 21,706,889 gals.; daily average for wet weather, 32,131,655 gals. This was an increase of about one-half in wet weather. The system is a separate system. The sewers, from 16 ins. in diameter up to the largest size, are brick. The pipe sewers range in size from 6 to 15 ins., and are partly iron and partly vitrified pipe.

Baltimore, Md.—In the new system being installed, notwithstanding careful waterproofing of interceptors, and the use of waterproofed joints, provision is being made in the size of the sewers for the entrance of some ground water. The Board of Consulting Engineers say, in their report to the sewerage commission (1906):

From our experience with this subject in other places, it is our opinion that in the earlier years of the new works, the total amount of the sewage would not exceed the water supply. In subsequent years, when the sewers are extended into less thickly populated portions of the city, and buildings are more generally connected with the sewers, the sewage increased by ground water will be materially in excess of the water supply.

The board advised providing for 150 gals. of flow per capita with sewers designed to flow half full with this quantity. The system is separate. Vitrified clay pipe is used for all pipe sewers.

Columbus, O.—Ground water entering sewers, when ground is wet after storms, is about 100 per cent. of the dry weather flow; during storms it ranges from 100 to 296 per cent. of the dry weather flow. System is built of brick, vitrified clay and concrete.

Kalamazoo, Mich.—Ground water entering sewers is about 20 per cent. of their capacity. System formed mainly of vitrified clay pipe.

Norfolk, Va.—Ground water forms 60 per cent. of the pumping. Sewers are brick, vitrified clay and iron pipe.

Canton, O.—Main sewer admits ground water at the rate of 70,000 gals. per mile per day.

Brockton, Mass.—The ground water flow is said by reports to have been 400,000 gals. per day from 16 miles of sewers, or 25,000 gals. per mile per day.

Red Bank, N.J.—Strictly separate system. No storm water is supposed to enter, but after a shower the flow quickly doubles in quantity. Vitrified clay and iron pipe are in use.

Vineland, N.J.—Strictly separate system of sewers constructed of vitrified pipe. The flow in wet weather is nearly double that in dry.

Westfield, N.J.—Strictly separate system of sewers constructed of vitrified clay pipe. There are about 15 miles of sewers 8 ins. to 24 ins. in size. The ground water entering the sewers increases the ordinary flow about 50 per cent.

Further interesting data on the amount of ground water infiltration are given by Mr. Kenneth Allen, chief engineer of the Metropolitan Sewerage Commission of New York. The following figures are from Mr. Allen's discussion.:

In Providence, R.I., the infiltration has been estimated at 47 gals. per capita per day.

In Waterbury the infiltration to a concrete sewer about 4 ft. 5 ins. square laid under a head of from 4 to 12 ft. amounted to one gallon per second for every 400,000 sq. ft. of interior surface, or 0.218 gal. per sq. ft. per day.

The infiltration of 140 miles of sewers in Massachusetts towns has been estimated at 40,000 gals. per mile daily. Taking the larger systems of the state it has been estimated at 70,000 gals per mile.

In the metropolitan system near Boston it has averaged 40,000 gals. per mile before making connections.

In their report on a system of sewerage for the city of Baltimore in 1897, Messrs. Hering and Gray recommended an allowance of 750,000 gals. per sq. mile in the low-lying districts near the harbor, and 100,000 gals. per sq. mile per day in other parts of the city. In 1906 Mr. F. P. Stearns proposed an allowance of from 30,000 to 80,000 gals. per mile of sewer daily. In later estimates 12 gals. per capita have been assumed.

Mr. C. E. Grunsky estimated for the sewerage of San Francisco a daily volume of 55,300 gals. per sq. mile for pipe sewers and 166,000 gals. per sq. mile for brick sewers.

In Peoria, Ill., the infiltration was estimated at from 50,000 to 100,000 gals. per mile for sewers in wet ground. In the case of brick sewers it was estimated at 15 gals. per sq. ft.

The above figures show the variation in the amount of ground water infiltration and indicate how serious the problem may become in some cases. Mr. Hammond considered it likely that his list could be extended to include nearly every sewer system installed in this country previous to 1900, and many since installed.

Methods of Waterproofing Sewers.—As Mr. Hering points out, waterproofing may be applied in three general ways. One way is to have the material of the structure and the joints impervious. This will prevent leakage in either direction. Another way is to coat the outside of the sewers if the object is to prevent infiltration of ground water into the sewer. The third way is to coat the inside of the sewer if a leakage of the sewage into the ground is to be prevented.

Mr. Hammond submits the following classification of the causes of failures and leaks in pipe sewers: 1. Pipe of improper material for sewers. 2. Defective or broken pipe. 3. Defective joints. 4 Defective house connections. 5. Improper foundations. 6. Careless or improper backfilling of trenches. 7. Improperly constructed brickwork and concrete. 8. Disintegration of pipe or masonry, caused by chemicals or impurities in solution in the sewage or in the ground matter, and from steam admitted to the sewers. 9. Failures from other causes not classified, as unexpected contraction and expansion, impact, etc.

Mr. Hammond discusses waterproofing methods as follows:—

"The waterproofing of sewers is perfectly practicable. The extent to which it should be employed, and the best method adaptable to a given case, are the problems to be met, as well as the probable length of time during which the waterproofing employed will continue effective, and the best should be selected for each special case.

"There are various methods here for producing the effect, as elsewhere. Coatings of bituminous materials may be applied to the external surface of the sewer, and gaskets dipped in tar or maltha or hot asphalt may be employed in the joints; or the whole interior of the sewer may, in the case of large masonry structures, be treated with a plaster. Again, the sewers may be designed to be built of concrete pipe rendered impervious by exterior coatings of asphalt paint or maltha; or by having an antihydrous waterproofing compound mixed with the cement used in the concrete. Recent experiments seem to show that even the admixture with the concrete of clay, or various other substances, will produce a dense and waterproofing material. Concrete rendered impervious by one of these methods may be used in forming the larger sewers in place, and in making the manholes and other appurtenances. Also, in the construction of pump wells and disposal works; and in various instances this method may be supplemented by the use of bituminous exterior coatings.'

"In Baltimore, where the most elaborate and extensive system of sewers now under way in this country is being constructed, and no detail is being lost sight of or expense spared which could render the system more perfect, the intercepting sewers are being treated with a complete waterproof coating."

In addition to the data given by him on the amount of ground water infiltration, previously quoted in this abstract, Mr. Allen discussed the methods and cost of waterproofing sewers. We quote, as follows:

"In the case of vitrified pipe sewers, if these are sound and of good quality, it only remains to secure an impervious joint. This is not practicable with natural cement. With Portland cement mortar following a gasket saturated with grout and carefully calked there will be very little leakage. The difficulty lies in ensuring perfect work, especially in a wet trench, and the possibility of cracking the joint by settlement in a soft soil. To overcome these objections various substitutes for the cement mortar joint have been used with more or less success.

"With a firm bed or foundation a mixture of 1 part of fine sand with 1 part of flour of sulphur heated to about 230° F. poured in the joint over a well calked gasket is said to give a water-tight joint costing for an 8 in. pipe 12 cts., for a 15 in. pipe 19 cts. and a 30 in. pipe 30 cts. Possibly leadite, which is somewhat similar in character and which the writer has used successfully for cast iron pipe joints would answer equally well. Either of these materials will provide a strong and unyielding joint, so that in case of settlement an undue strain is brought to bear on the bell.

"For yielding soils the writer believes some form of bitumen may eventually be found that will be both elastic and impervious. For a number of years Mr. J. H. Decker has used a paste made by kneading cement and pine tar pitch by hand until of the consistency of dough in the sewers of Atlantic City with success, the material being pressed into the joint by hand. The writer employed this method in laying about ¼ mile of conduit of 8 in. to 20 in. vitrified pipe conveying water from a series of artesian wells to a reservoir. Testing under a head of 3 or 4 ft. after completion, the line was found to be almost absolutely water-tight. This joint, although setting quite hard, remains sufficiently pliable to conform to ordinary settlement without injury.

"In Baltimore, Mr. E. B. Whitman experimented with a joint which proved so satisfactory that a considerable amount of vitrified pipe has been laid in wet trenches in the sewerage of that city with bitumen joints. The specifications provide that the inside of the bell and at least 4 ins. of the spigot end shall first be painted with a thin paint consisting of a solution of bitumen and gasoline or turpentine. Two or three pipe lengths are usually joined together before lowering to the trench by first centreing and packing with a thin gasket of hemp or jute well calked and then filling the joint full of hot bitumen, heated sufficiently to expel bubbles but not so as to render it brittle. The bitumen may be the refined natural or artificial material or a mixture of both, but must not have a melting point lower than 170° F. or be brittle when cooled to 30° F. It must also be of such a consistency that a fragment will not materially alter in shape when kept in

ordinary temperatures and must have a moderate degree of resilience.

"As a test it is specified that 3 lengths of 8 in. pipe joined in this way and resting on supports 7 ft. apart shall carry a centre load of 200 lbs. without failure or excessive deflection, and that after such tests the joints shall show no leakage when subjected to a hydrostatic pressure of 5 lbs. per sq. in.

"Asphaltic joints have been used to a considerable extent in England and Germany, and the writer has long believed that a field would open for them in this country under conditions where cement work would be injured by washing or, later, by cracking.

"With larger sewers it is desirable to employ concrete in preference to brick if watertight work is desired. There is no question but that reasonably tight work can be secured by using correct proportions and a wet mixture, but additional safety may be had by the use of waterproofing compounds by the judicious admixture of lime or clay to the concrete or by the application of a layer of waterproofing material. The writer believes that the latter safeguards are rarely required in sewer work when good work can be relied on by contractor and inspector.

"In the construction of the west low level interceptor at Baltimore, waterproofing was applied to the interior surface of the concrete and a brick ring added inside to protect this. The diameter on sections 1 and 2, which lay along the waterfront with the invert from about 11 to 13 ft. below tide level, were from 74 to 84 ins. The invert was first swabbed with hot Trinidad asphalt upon which was placed a layer of 10 oz. burlap. This was then rubbed down and painted with hot asphalt, a second layer of burlap applied and this was then brushed down and saturated with a third coat of asphalt. The brick ring was then laid complete and the waterproofing carried over the brick arch. The concrete arch was finally laid on this.

"Some difficulty was experienced at first from the water which dripped on the tops of the side walls and found its way between the waterproofing and concrete of the invert, forming blisters 1 or 2 ins. in diameter. Where this occurred the blisters were pierced, emptied and patched. To prevent its recurrence channels were left in the tops of the side walls to cut the flow from outside and the lap of the burlap rolled up and covered with canvas to keep it as dry as possible.

"In forming the joint with the waterproofing of the arch the layers were lapped in pairs and an additional strip of burlap added outside, making the waterproofing at this most troublesome location 5-ply.

"To drain the channels left in the side walls 3 in. terra cotta drains were inserted, occasionally running down through the side walls to a quarter bend and thence to the gravel near the under drain.

"If the burlap got wet, as was sometimes inevitable, it was dried with a gasoline torch, although in extreme cases this was not practicable. To dry the invert before waterproofing, if too damp, gasoline was sprinkled on and lighted, but in sparing quantity to avoid injury to the concrete. At other times it was merely sprinkled with dry cement, which absorbed the moisture and was then brushed off.

"Estimates of the actual cost were made from time to time with the following results:—

	Per lin. ft.
Cost of waterproofing 84-in. sewer	$1.60
Cost of waterproofing 80-in. sewer	1.53
Cost of waterproofing 76-in. sewer	1.45
Cost of waterproofing 74-in. sewer	1.41

Cost per square yard:

Burlap at 6.9 cents per square yard	0.17
Asphalt at 25 cents per gallon	0.48
Labor	0.18
Total	$0.83

"The force employed usually consisted of a foreman, two laborers and two helpers.

"On section 3 the cost was reduced by the substitution of tar pitch for asphalt. Difficulty was experienced in securing a material that would neither be too soft at high temperature nor brittle at low temperature, but in other respects the results appeared satisfactory. The tar pitch cost $8 per 1,000 lbs., resulting in the cost for this material of but 15 cents per square yard of waterproofing.

"After the completion of the 3,590 lin. ft. of interceptor, about 100 ft. of which passed under the bed of a tidal stream, the leakage, including that from over 2,700 ft. of house connections and a considerable inflow around a bulkhead at the upper end of section 2, amounted to 11.16 gals. per min., or 0.223 gals. per sq. ft. of interior surface of interceptor (only) per day. The actual infiltration through the interceptor was practically nothing, as the water observed entered chiefly around the bulkhead mentioned, through the laterals or at the junctions with the interceptor. Probably 1/10 gal. of ground water per sq. ft. per day would be a liberal estimate in estimating on similar work. Considering the relative elevation of the ground water and the great difficulty in keeping the burlap at the spring-line dry while turning the brick arch, the final result was most satisfactory."

DRAFTING OF FORMS EFFECTS BIG SAVING EVEN ON SMALL, PLAIN JOB.

It is generally recognized that one of the prime reasons for the comparatively high first cost of reinforced concrete buildings is the cost of the material and labor put in the forms. Therefore continued efforts to reduce this item to a minimum are being made by many construction companies. A recent case of the Aberthaw Construction Company, of Boston, is illustrative of the possibilities of saving even on small jobs by designing the forms in the drafting room instead of putting the fitting up to the carpenter shop.

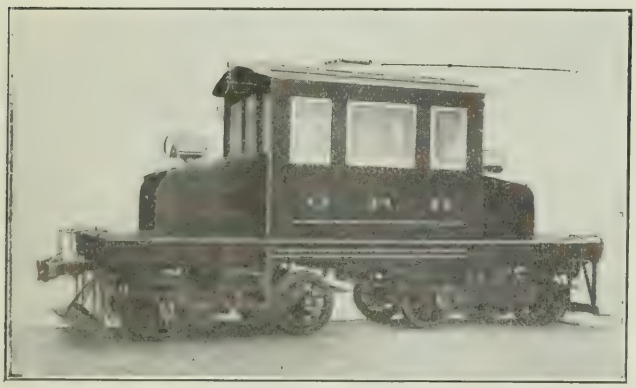
The job in question was a small structure costing about $26,000, and 50 ft. x 50 ft., four stories high. The design was of the beam and girder type, and was made as regular as possible in order to keep the cost down. In spite of this 115 different kinds of forms were required, making a total of about 500 forms in all, taking about 10,000 sq. ft. of stock. When it is considered that figures do not include any of the ledges, studs, or anything but the beam and column sides, it will be appreciated that 113 different kinds of forms is a large number for a plain, small job.

According to the company's former methods the carpenters not only made the beam sides but fitted them as they went along, and each one had to be sawed out. A large saving is therefore made by designing the forms for this small job in the drafting room, as the cost of drafting is very much less than the cost of making up the beams and fitting. It is very probable that the failure of new concrete contracting companies is often due to their ignorance of economical methods of handling form work, and the case above is an excellent illustration of how they might go astray on their estimate by not realizing the high cost of the many forms on such a small plain job.

27-TON LOCOMOTIVE FOR THE GUELPH RADIAL RAILWAY COMPANY.

The Guelph Radial Railway, Guelph, Ont., has recently purchased a 27-ton Baldwin-Westinghouse direct current locomotive. The cab, trucks and all mechanical parts were built by the Baldwin Locomotive Works, and the electrical equipment, including motor and control, was furnished by the Canadian Westinghouse Co., Limited, of Hamilton, Ontario, after the design of the Westinghouse Electric & Manufacturing Company, of East Pittsburg, Pa.

This locomotive is compactly built and may be used for freight and switching service. Interurban and city railways are using locomotives like this one and larger for various kinds of service, for a road's earning capacity can be materially increased by using locomotives to haul freight during the night or idle hours, thus improving the load factor. Many city roads also use similar locomotives for hauling construction material and refuse to dumping grounds.



New Locomotive for Guelph Radial Railway.

The Guelph Radial Railway locomotive is ruggedly built. The frame is of channel iron construction, and the cab is substantially built of clear ash fitted together with joint bolts and corner plates. The trucks are of the standard Baldwin electric M.C.B. equalizer-bar type with chilled cast iron wheels.

The electrical equipment consists of four type No. 101-B-2, 40-h.p., 500-volt Westinghouse railway motors and K-28-B control. It is also equipped with Westinghouse automatic and straight air brakes, with outside equalizing driver brakes.

The principal dimensions are:—

Length over end sills	23 ft. 0 in.
Width over all	8 ft. 0 in.
Truck centres	12 ft. 0 in.
Rigid wheel base	6 ft. 0 in.
Total wheel base	18 ft. 0 in.
Wheel diameter	33 in.

The hauling capacity of this locomotive is given in the table below:

Number of cars weighing 45 tons with load at 10.75 miles per hour at 500 volts.

Straight level road.	*Maximum Grade. ½%	1%	2%
17 cars.	7 cars.	4 cars.	2 cars

*On a fairly level and straight road, the load to be handled is determined by the maximum grade.

The figures given for "straight, level road" show the load which may be handled in switching service. The values given under "maximum grade" are safe when the grade requires a pull of but five or ten minutes' duration. In any particular case, the number of cars that can be handled may be greater or less than the values above tabulated, depending upon the profile curves and operating conditions.

HINTS FOR DRAINAGE SURVEYS.*

By I. W. Hoffman.

In many localities some drainage work has been done that proved to be no good. Usually it has been done without a survey, and it all had to be abandoned, and the work done over again.

In making preliminary surveys for county drains or drainage districts, I use stations 100 ft. apart, and only drive marker stakes. I take the levels simply on the ground, and when construction commences, put in the pluses and replace the markers, if any have been obliterated. On tile drains I put in plus stations every 50 ft. In that way the profile will be accurate and the exact depth of cut ascertained, or very nearly so. The profile should show the depth of the cut. It is well to put records of bench marks on the profile, as well as the length of drain that passes through the property of the different land owners; also the intersections with different subdivision lines and roads or highways.

The map should be made so as to show the surface conditions of the district (the points of the wet land, low land, or high land) and it should be as nearly accurate as it is possible to make it. The better the map is made, the more easily the board of supervisors can determine conditions in the district. The tracings of the map and profile should be kept by the engineer, and not allowed to be handled by the board of supervisors or other persons to any great extent. Blueprints can be made from these and filed in the reports. By the direct white-print process the map is made direct from the tracing and it shows everything plainly. It is made exactly as a blueprint. You do not have to make a negative; simply expose your tracing about seven minutes in bright sunlight, wash it, and you have a white print. You have a map then that can be taken by the commissioners and the classifications can be written on each 40-acre tract.

The engineer should make a complete and comprehensive report to the board of supervisors on every drainage district that he lays out. It is better to put in a little too much than not enough, so that the board will fully understand the conditions, the descriptions of the various drains, their approximate cost, and any recommendations the engineer sees fit to make. The engineer should keep a copy of everything that he does in his office. If some of the papers get lost in the auditor's office, which may happen, he then has copies to which he can always refer.

The engineer should try to attend all board meetings, but especially should he be present when the drain is to be established. These board meetings may sometimes be very animated, but he should face the music. It is particularly desirable for him to attend the meetings also when final action is taken on the assessment of benefits. There may be things that the engineer can explain to the satisfaction of the board and to the satisfaction of the land owner.

The engineer should try to accommodate the landowner in all things that can fairly be done. A landowner may wish a slight change sometimes, before the work is finally established or before the report is made. If he can be accommo-

*From the Proceedings of the Iowa Engineering Society, 1911.

dated without infringing on the capacity or use of the drain, this should be done.

The lines for the drains should be run as straight as possible, at the same time the line of the drain should follow the lowest depression. The engineer is one of the commission to appraise the damages in a drainage district. The damages asked for are sometimes a great deal more than will be allowed by this commission. The commission on damages should use judgment, and not allow any more than is fair and just.

The assessment of benefits is a very hard proposition. The drainage district should be examined very closely, each tract by itself, and all of the facts weighed and sifted until an equitable apportionment can be made by these commissioners. If this apportionment of taxes has been made in a just and fair manner, the board of supervisors should not change it. A great deal of trouble has resulted by boards changing the assessment.

The engineer and contractor should be on good terms always. The engineer should use judgment and have the contractor work to the line, but should not unnecessarily hamper the work of the contractor, who often has a very hard job before him. The drains should be laid out and constructed upon the best lines and no deviation made from them, and they should be constructed in such a manner as to do the most benefit to the land. The people are paying for it, and they expect the construction of these drains to be such as will be a benefit to them.

ACTION OF WATER ON LEAD PIPES, ETC.

Before the Chemical Section of the British Association, Dr. F. Clowes presented a paper on the action of distilled water on lead. When some years ago it was proposed to bring large volumes of soft water from Wales to London, the possibility of the action of this water on leaden pipes had to be investigated. Dr. Clowes had experimented with large sheets of very pure commercial lead. This lead was not acted upon by distilled water in a vacuum nor in an atmosphere of hydrogen; at any rate, the action, due probably to the last traces of oxygen, was infinitesimal. But supply waters always contain oxygen and also other gases. Of these gases, oxygen when alone present attacks the lead worst; carbon dioxide has a very slight effect; in equal mixtures of oxygen and carbonic acid the effect is quantitatively that of the oxygen, and when more CO_2 is present the action becomes less pronounced. The corrosion of the lead is hence primarily due to oxygen; the carbon dioxide acts in the second place by forming a carbonate with the oxide first produced. The action is rapid at first, and a white deposit is formed, while some lead passes in solution; the deposit in some hydroxycarbonate of variable composition. It has been suggested that the presence of bacteria was required to start the attack, or would hasten it; but heated lead corroded as quickly in water which had long been kept boiling as under ordinary conditions. These experiments demonstrated, however, the inhibitory influence of certain salts in the water. When water is distilled with the aid of a glass condenser tube, some silicate passes into the distillate, and this silicate protects the lead against corrosion. The water was therefore distilled from copper vessels and passed through copper coolers in some experiments. Sulphates also protect the lead, carbonates and carbonic acid are less efficient, lime is doubtful, and may even increase the corrosion if sufficiently concentrated. It is also due to this protective power of salts that distilled water does not acquire its full corrosive activity on subsequent aeration by exposure.

PROTECTION OF STEEL PIPES.*

By Alfred D. Flinn.

One of the siphons of the aqueduct under construction to supply New York City with water from the Catskill mountains was described in our issue of August 23. At that time the steel work of the siphon had not been completed, and consequently only a brief description was given of the protection, both inside and out, which was contemplated. In a paper before the New England Water Works Association, Alfred D. Flinn, Department Engineer of the Board of Water Supply of New York City, described the methods employed for furnishing inside and outside protection to this siphon and to the others along the line of the aqueduct. Of these siphons there are fourteen, ranging in length from 608 feet to 6,671 feet, the total length of all the siphons being 33,031 feet. About one-fourth of the total length has a finished inside diameter of 10 feet 11 inches, about one-fourth a diameter of 9 feet 5 inches and about one-half a diameter of 9 feet 2 inches.

While preparing the plans, investigations and experiments were conducted to determine the material and method which it would be best to adopt for protecting the steel. Apparently none of the pipe coatings commonly used possessed qualities giving it more than a few years' useful life when in contact with the water and soil which had to be considered in this case. One or two cases of the use of Portland cement mortar on a small scale and wide experience in reinforced concrete construction suggested the use of cement for this purpose; and after some study it was decided to jacket the siphons outside with rich concrete, with a minimum thickness of 6 inches and line them with Portland cement mortar 2 inches thick. An effort was then made to find the most economical and practical methods for the various steps in covering and lining the pipe, with a view also to obtaining intimate, complete and permanent adhesion in spite of the unavoidable changes in shape and the elastic distortions of the pipe.

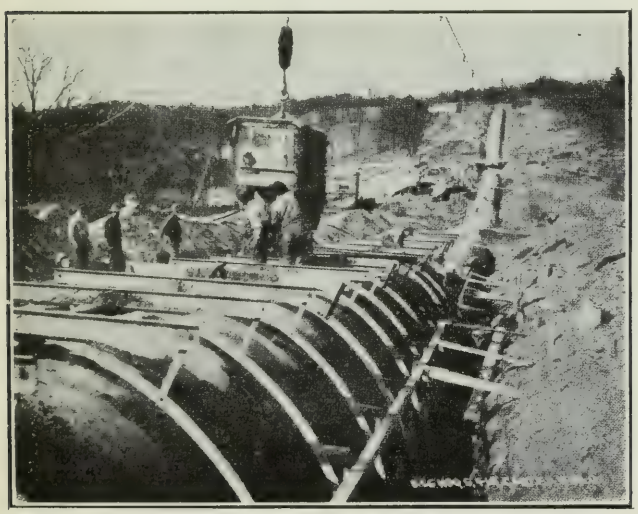
Mortar lining experiments were made on a steel pipe 9 feet in diameter and 12 feet long. This was lined by plastering with metal reinforcement of several styles, by plastering with terra cotta and cement blocks or tiles, and by pouring grout or very thin mortar into the space between a cylindrical steel form and the interior surface of the pipe. These experiments seemed to show that no combination of plasterer's skill with various kinds of cement mortar, reinforced or unreinforced, gave linings that were adequate; besides which this method was expensive. Bedding tiles of terra cotta or mortar, about ¾ or ⅞ inch thick and 6 by 8, 6 by 12, and 8 by 12, on mortar applied directly to the pipe surface, and, after setting, building up the lining to the required thickness with successive coats of mortar troweled on, was much more satisfactory, but also expensive. The grouting method proved by far the most satisfactory and least expensive and was made the basis of the specifications. It had the advantage of producing a monolithic lining, which was considered desirable, especially as it avoided layers or laminae, since it is well known to be difficult to cause one layer of Portland cement mortar or concrete to adhere absolutely and permanently to another without expensive and troublesome precautions. This method also gave promise of being feasible in actual construction, and was adopted for the work.

The specifications as adopted provided that the pipe should be tested by filling with water, should be made tight

*Abstract of paper before the New England Water Works Association.

while under pressure, and while still under the normal pressure should be surrounded with concrete, the pipe being kept under hydrostatic pressure until the concrete last placed had set for at least 48 hours. The water was then to be withdrawn from the pipe and the interior lined. It was provided that the lining should consist of Portland cement and sand mixed in such proportions as might be ordered, but probably one part of cement to two parts of sand. The lining was required to be of substantially uniform thickness throughout the entire circumference except for the unavoidable variations due to lap of the plates, butt straps and rivet heads.

The steel was required to be free from rust immediately before the application of either outer coating or inner lining. As a partial protection against rusting during transportation and construction, each pipe, after being pickled at the works, was given a coat of heavy lime whitewash, made as follows: To one barrel of whitewash (about 50 gallons), there were added 20 pounds of glue. After using this whitewash for a time, about one pound of Portland cement was added for each gallon of whitewash. The glue was dissolved in water before being added to the whitewash. The whitewash was applied with brushes, a machine for spraying by compressed air being found unsatisfactory. The whitewash did not adhere very well, some of it being removed almost as soon as applied. This temporary coating, however, did not suffer from abrasion or cracking off so much as from exposure to the weather; and even where the whitewash was not disturbed, light rusting occurred. In fact, the pipes arrived at the trench with more or less complete coats of light yellow rust; but there were no indications of any tendency to pitting, and the rust and the whitewash which remained were removed, before applying the concrete or mortar, by the use of wire brushes, although for some of the worst places steel scrapers were also employed. Inside some of the siphons the surfaces of the plates were rubbed with empty cement bags after the wire brushing.



Placing Concrete in Jacket, Showing One Type of Forms.

The methods employed for placing the concrete jacket were practically the same as those commonly used for concrete conduit construction, in which steel centres take the place of the steel pipe. On one siphon three methods were employed in different parts; monolithic; the invert first, then the remainder; invert and side walls to the horizontal diameter, then the arch. The best contact between jacket and pipe was obtained when the concrete was placed monolithically. Incidentally it was found that dropping concrete on to the pipe so as to cause shock should be avoided, a two-foot drop being too great. Earth covering was placed immediately after the completion of the concrete jacket, to protect it from accident and from temperature changes. For this reason there has been little chance to observe what tendency to crack there may be; but so far as has been observed, there have been very few cracks in the jackets of any of the siphons built so far.

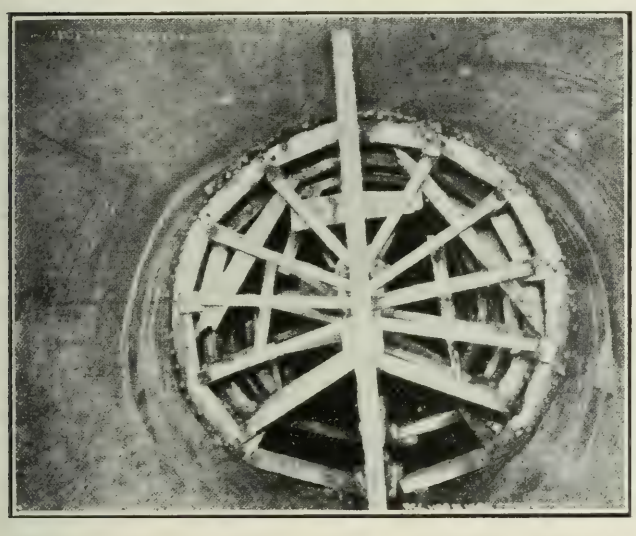
For lining the pipes two distinctly different methods were first adopted by the two contractors. On the northern half of the aqueduct, grouting with forms was employed, and on the southern half the mortar has been applied to the first siphon by the use of the cement gun. There were practical difficulties connected with the use of a complete cylindrical form, such as getting around curves, vertical or horizontal, collapsing one section of forms sufficiently to pass forward through another section which must remain in place while the grout is hardening; cleaning, lubricating and inspecting outside of form, etc. Consequently the invert for a width of about eight feet of arc has been placed first by methods similar to those of concrete sidewalk construction. These wide inverts have generally separated from the pipe along their edges, for one reason or another, so that a piece of steel tape could at places be pushed into the crack for several inches. To obviate this trouble trials have been made of inverts one foot to two feet wide.

In both contracts wooden forms in panels 2 feet wide and 15 feet long, adjusted on modern rings and firmly braced, were used for pouring the remainder of the lining in 15-foot sections at one operation. The grout is poured from outside the pipe through a 2½-inch wrought iron pipe secured into a rivet-passing hole. In the southern department this pouring pipe is at the downhill end of the section and is long enough to give a head of about four feet at the top of the uphill end. A vent pipe is fastened in the uphill rivet-passing hole of the section, the bulkhead forming the end of the lining being placed just beyond it. The contractor for the northern siphons used, for pouring grout, two mortar boxes set on a temporary staging over the upper end of the section to be grouted. The mortar was mixed to the proper consistency in alternate boxes and allowed to flow into the pipe through a hole controlled by a sliding wooden gate. All mixing was done by hand and materials were carefully graded. It generally took about two hours to fill a section, after which a man was kept on for another hour or two in order to feed in sufficient grout to get the desired consistency. There was a noticeable tendency to get a porous or thin condition at the upper end of the section near the grouting hole. To avoid this the riser was removed two or three times during the pouring and the thin material which collected at the top was allowed to escape; when the riser was put back and grout added as necessary. In some cases it took nearly two hours after the main operation to get grout of proper consistency at the foot of the riser. At the finish of the pouring a small pipe was inserted through the large pipe, to permit the escape of the last air while grout was being poured through the larger pipe, and was churned into the small remaining space to insure complete filling. For the first batches, or nearly up to the horizontal diameter of the pipe, the grout was mixed one part cement to one part sand; the upper part was mixed about one to two. The rate of pouring the lining depended upon the number of forms and men available. In lining the Foundry Brook siphon about two moves per week were made with each of twelve sets of 15-foot forms, the rate being about 400 feet per week.

The cement gun builds up the lining in layers, but these are applied in such rapid succession and each layer has such a rough surface that there is little or no lamination. It was impossible, however, to secure a satisfactory smooth finish in this way, and a final layer was applied and floated and

troweled before it hardened. In using this gun charges of dry sand and cement are placed in the chamber of the machine and then rapidly discharged by air under 50 to 60 pounds pressure through a rubber hose; water under pressure being brought by a parallel hose and combining with the cement and sand in a special nozzle. The nozzle pressure is about 30 pounds and the resulting velocity causes an excellent union between the layers; but it also results that a measurable proportion of the sand bounds off the surface of the pipe and falls to the invert, especially when beginning the first layer on the bare steel. This dry material, which averages one part cement to 3¾ parts sand, is collected and used in making the invert. The use of the gun causes the atmosphere within the pipe to be very dusty, and artificial ventilation is consequently necessary. The grout applied by the gun is considerably less moist than that poured within the forms, and consequently more attention is required to keep the lining moist in order to minimize shrinkage cracks, a considerable number of fine cracks having formed in the lining first placed in this way. In spite of these difficulties a satisfactory lining has been secured; but the contractor discontinued its use after completing one siphon, the reason given being excessive cost.

Absolute adhesion of concrete or mortar to the steel has



Wooden Form for Mortar Lining. Completed Lining in Foreground.

not been secured at all points, as has been proved by careful sounding with a hammer; but on cutting out hollow-sounding spots, the space between the mortar or concrete and the steel has usually been found almost infinitesimal in width. What effect this would have on the protective action of the lining was investigated by the Board's laboratory. One of these tests consisted in placing horizontally in a galvanized iron tank six steel plates 8 x 16 inches, separated from the bottom by two 1¼-inch bars of alberene stone and from each other by ½-inch wood dowels. The first pair of plates had no protective covering; the second pair had their upper surfaces protected by a slab of cement mortar 2½ inches thick, held from contact with the steel by two metal strips about .04 inch thick; the third pair of plates was protected by cement mortar slabs 2 inches thick, cast directly on the steel, and apparently adhering to it firmly. The tank was filled with Croton water to four inches above the uppermost mortar slab, the water being renewed twice monthly, and the slabs being immersed for two years. Each slab had been cleaned by pickling and rubbing with emery cloth before treatment. At the end of the two years the first plates showed heavy corrosion. The second pair of plates showed a very slight corrosion, most of which washed off, thus indicating a considerable protective influence under the conditions described. When the mortar was removed from the third pair of plates it was found that a part of the surface of the steel had a distinctly different appearance from the other part. One part was clean and wet; the other was covered by strongly adhering particles of mortar and was dry, thus indicating that there had been actual adhesion of the mortar over the latter part of the surface only, and that the former had been separated by a space large enough for the water to enter. There had, however, been no rusting except at some places near the edges of the wet part of the surface, where apparently the space had been sufficient to allow circulation of the water. The water in the rest of the space had evidently been so highly charged with lime that no corrosion could take place.

Another experiment was made by immersing ¾-inch round soft steel rods in slabs made of rather lean concrete which, after about two years, were broken and found to be thoroughly saturated, but the rods showed no sign of corrosion whatever. It is hoped that the pipes will last one hundred years and even longer, because of the cement lining. In addition, because of the gain in smoothness of the interior surface obtained by covering the rivet heads and plate laps, it is computed that the hydraulic capacity of the three pipes would be as great as that of four unlined ones.

The contract prices of the several siphons, all of which were let in two contracts, were as follows:

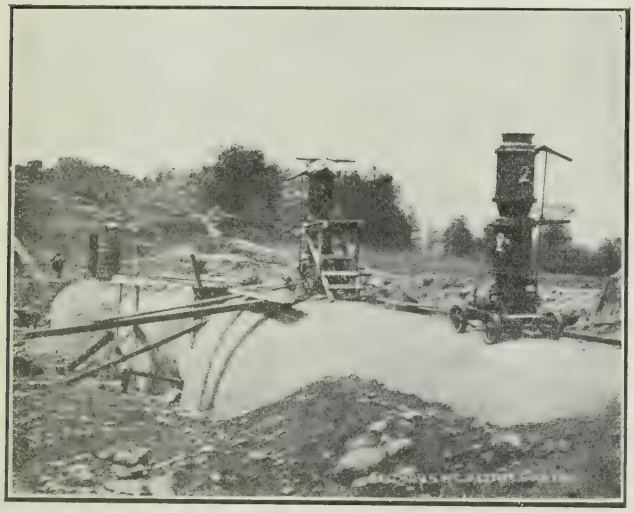
Contract Prices for Steel Pipes, Concrete Jacket and Mortar Lining.

Description.	CONTRACT 68. Contract price.		Average of all bids. (5 bidders.)	
9 ft. 6 in. steel pipe, 7/16-in. plate, lap-jointed	$31.00	lin. ft.	$35.50	lin. ft.
9 ft. 6 in. steel pipe, ½-in. plate, lap-jointed	35.00	" "	41.20	" "
9 ft. 6 in. steel pipe, ½-in. plate, longitudinal seams, butt-jointed	40.00	" "	44.80	" "
9 ft. 6 in. steel pipe, 9/16-in. plate, longitudinal seams, butt-jointed	43.00	" "	48.80	" "
9 ft. 6 in. steel pipe, 11/16-in. plate, longitudinal seams, butt-jointed	47.00	" "	55.80	" "
9 ft. 6 in. steel pipe, ¾-in. plate, longitudinal seams, butt-jointed	50.00	" "	50.60	" "
Mortar lining for steel pipes	2.50	" "	4.90	" "
Reinforcement of mortar lining for steel pipes	.02	sq. ft.	.03	sq. ft.
Concrete masonry around steel pipes	6.00	cu. yd.	5.85	cu. yd.
Portland cement	1.75	bbl.	1.74	bbl.

	CONTRACT 68.		(8 bidders.)	
9 ft. 9 in. steel pipe, 7/16-in. plate, lap-jointed	$29.00	lin. ft.	$33.25	lin. ft.
11 ft. 3 in. steel pipe, 7/16-in. plate, lap-jointed	33.00	" "	37.37½	" "
11 ft. 3 in. steel pipe, ½-in. plate, lap-jointed	38.00	" "	42.75	" "
11 ft. 3 in. steel pipe, ½-in. plate, longitudinal seams, butt-jointed	46.00	" "	48.75	" "

11 ft. 3 in. steel pipe, 9/16-in plate, longitudinal seams, butt-jointed	50.00 " "	53.62½ " "
Mortar lining for 9 ft. 9 in. steel pipe	3.00 " "	3.56¼ " "
Mortar lining for 11 ft. 3 in. steel pipe	3.50 " "	4.04½ " "
Reinforcement of mortar lining for steel pipe	.02 sq. ft.	.02¾ sq. ft.
Concrete masonry around steel pipe	5.25 cu. yd.	5.78 cu. yd.
Portland cement	1.60 bbl.	1.72½ bbl.

In immediate charge of the construction of the siphons are Division Engineers John P. Hogan, Alexander Thomson, Jr., and George P. Wood on the northern; and George



Cement Guns Resting on Concrete Jacket.

G. Honness, Ernest W. Clarke and Charles E. Wells on the southern department. J. Waldo Smith is the chief engineer of the Catskill water works, Merritt H. Smith is deputy chief. Many of the investigations of existing pipe lines were made by the assistant to the chief, Department Engineer Thaddeus Merriman.

In discussing the matter of preparation of the steel, F. N. Speller, metallurgical engineer for a Pittsburg firm, highly approved of the careful removal of the mill scale. He stated that experiments in which two parts of the same plate, one with and the other without the scale removed, had been exposed to corrosion showed about the same loss of weight per unit area in both cases, but this corrosion was in the form of deep pitting in the uncleaned surface, but uniformly distributed and with little damage in the other. A 5 per cent. solution of sulphuric acid, heated to about 180 deg. Fahr. when used, he thought the most effective conditions for removing scale by pickling.

BROKEN RAILS AND DEFECTIVE WHEELS.

In a recent report of the Interstate Commerce Commission of the United States, note is made of the number of broken rails and defective wheels. The Commission state that their attention has been called in numerous and in some instances startling ways, to the increased number of railroad accidents due to broken rails. The reports of accidents made to the Commission by carriers show that in the year ended June 30, 1902, 78 derailments were caused by broken rails, while in the year ended June 30, 1911, 249 derailments were due to the same cause. In the past decade 2,059 derailments have been caused by broken rails and have resulted in the death of 106 persons and injuries to 4,112 persons.

Exhaustive investigation was made of a wreck on the Lehigh Valley Railroad on August 25, 1911, in which 62 persons were injured and 29 persons lost their lives. There was and is no room for doubt that this wreck was caused by a broken rail. The Commission requested the co-operation of the Department of Commerce and Labor by its Bureau of Standards in examination of pieces of this rail. Inspection and careful analysis of same disclosed that the rail contained defect in manufacture and several other defects in the form of transverse fissures. This rail was manufactured in December, 1909, and was laid in the track in October, 1910. It had, therefore, been in use less than one year when the accident occurred. The reports of this accident suggest that the defects from use indicate that possibly the maximum weight of power and rolling stock that can safely be used on rails of present-day manufacture has been reached, if, indeed, it has not been passed.

Officials of railroad companies and of steel manufacturing plants are energetically pursuing careful investigations on this subject and apparently are determined to locate the difficulty and to correct it.

We deem it proper to call this situation to the attention of Congress, although we do not recommend that this Commission be authorized or directed to conduct an investigation in the premises. Any such investigation, whether conducted by carriers, steel manufacturers, or others, must of necessity be made on purely scientific lines, and if undertaken by the government there are doubtless bureaus in other departments that are equipped to do such work with competent men in the government service.

The attention of the Commission has been called to dangers in railroad operation from car wheels that are defective or composed of improper material.

The wide interchange of equipment between railroads necessarily frequently requires that broken or worn-out wheels shall be replaced on the lines of some carrier other than the owner of the car. It appears that such replacements are made under an agreed and standard price to be charged for the wheels.

We know of no existing statistics or information upon which statements as to the number of defective wheels discovered in service can be verified. No reports are made to the Commission of such instances unless a wreck or derailment is thereby caused. For the years ended June 30, 1902, 1906 and 1911, reports of accidents made to the Commission show for the respective years 538, 1,007, and 986 derailments caused by broken or defective wheels.

This suggests the possible desirability of requiring comprehensive reports from carriers as to the number of car wheels in use on their equipment and the number of same that have proven defective, by years, for the last decade. It is well known by all practical men that car wheels will crack from overheating by too long continued application of the brakes, and while presumably a wheel of poor material and workmanship would crack from this cause somewhat more readily than a wheel of good material and workmanship, it would seem proper in requiring such reports and analyzing same to differentiate wheels which are known to have been cracked or broken in this manner from those which have proven defective from other causes.

The suggestions already made as to an investigation of the quality of rails apply to any investigation undertaken as to the character and quality of material used in manufacturing car wheels.

METHODS OF REFUSE DISPOSAL FOR TORONTO.

In a report to the City Council, submitted on October 25th, 1911, Messrs. Rudolph Hering and John H. Gregory, consulting engineers, of New York, gave the results of their investigation into the refuse disposal question of Toronto. A digest of this report follows:

Four separate projects were considered: Two contemplated the incineration of the garbage, rubbish, and a portion of the ashes, (A) without and (B) with the utilization of the salable part of the rubbish. The other two projects provided for the reduction of the garbage and the incineration of the rubbish. (C) without and (D) with the utilization of the salable part of the rubbish. Street sweepings, dead animals, etc., are satisfactorily disposed of by the city's present methods and are not considered in the report.

The comparison of the four projects is based upon plant capacities sufficient to dispose of the refuse from a population of 600,000, which, it is thought, will be reached in 10 years; Toronto's population by the 1911 census is 376,240. The total weight of garbage, rubbish and ashes collected in Toronto amounts to about 0.55 ton per capita per year; the relative amounts per capita per year are, garbage 0.1 ton, rubbish 0.05 ton, and ashes 0.4 ton. On this basis the total estimated weight collected from a population of 600,000 would be 60,000 tons of garbage, 30,000 tons of rubbish, and 240,000 tons of ashes per year, a total of 330,000 tons.

Project A.—In this project it is proposed that all of the garbage and rubbish, together with ashes amounting to 20 per cent. of the mixture, be incinerated, the remainder of the ashes to be used for fill. With a population of 600,000 the average daily amounts to be incinerated would be: Garbage, 200 tons; rubbish, 100 tons; ashes, 75 tons; total, 375 tons. Studies of the cost of construction and cost of hauling led to the conclusion that two incinerator plants, each of a daily capacity of 215 tons of mixed refuse, would be sufficient. In project A it was assumed that the garbage and refuse would be collected together and the ashes separately. No boilers or equipment to produce power are considered in this project on account of the cheapness of electric power from Niagara Falls. As there is believed to be no market for clinker at present in Toronto no clinker mills are included in the cost of construction.

The cost of constructing the two incinerators is estimated at $478,400. The operating expenses, including interest and sinking fund charges, are given as $124,940 per year for the two units, or at a rate of $1.11 per ton of refuse handled.

Project B.—Project B, for two 195-ton incinerators, is similar to project A, except that the garbage and rubbish are to be collected separately and sorted over to recover salable material. Only a portion of the ashes would be delivered at the incinerators, the remainder being used for filling. The estimated average daily weights to be handled in project B are somewhat less than in project A. For 600,000 population there would be 200 tons of garbage, 67 tons of rubbish, and 68 tons of ashes daily, a total of 335 tons. It is assumed that two-thirds of the total rubbish collected would be burned, the other one-third being picked out and sold.

The estimated cost of constructing the two 195-ton incinerators, including means for picking out and handling the salable portions of the rubbish, is estimated at $489,300, with annual gross operating expenses of $166,570. In Buffalo, N.Y., the average receipts from the sale of material picked out from the rubbish for a period of over 4 years were $2.34 per ton of rubbish handled; on the basis of $2.25 per ton for Toronto the sale of the picked material will yield an income of $67,300 per year, thus giving a net annual cost of operation of $99,070, or 89.9 cents per ton of refuse handled. By comparing the operating cost of projects A and B it is seen that the picking out of the salable parts of the rubbish will result in an estimated annual saving of $25,870.

Project C.—In this project it is proposed that the garbage, rubbish, and ashes be collected separately; that the garbage be disposed of by the reduction process (grease and tankage being recovered); that all of the rubbish be incinerated; and that all of the ashes be removed to dumps and used for reclaiming low land. The average daily amounts to be disposed of, under this project, with a population of $600,000 are: Garbage, 200 tons; rubbish, 100 tons; ashes, 800 tons; total, 1,100 tons.

Project C provides for two 60-ton rubbish incinerators within the city limits and a garbage reduction works located about 10 miles east of the city near the shore of Lake Ontario. At each incinerator site it is proposed to install a loading-station with a railroad siding extending through it. Garbage wagons would be driven into the building and their loads dumped into special steel railroad cars of 40 tons capacity each, the car-body to be semi-circular and set on trunnions to facilitate the discharge of its load at the reduction works.

The reduction works would have a capacity of 240 tons per 24 hours and would comprise an unloading building, conveyor, digester building, containing digesters and presses for the cooked material, a dryer building where the moisture from the pressed tankage would be driven off, and a percolating building in which grease would be extracted from the dry tankage by means of the naphtha process. The liquids removed from the digester building would go to a grease separating and evaporating building. The syrup resulting from the evaporation of the liquids remaining after the grease had been drawn off would be mixed with the percolated tankage and dried, after which the tankage would be ready for shipment. It is proposed to operate all of the equipment at the reduction works power-plant by electricity, purchased from the Hydro-Electric Commission.

The estimated cost of constructing the two 60-ton rubbish incinerators, without means for picking out the salable material, is $227,700, including land. The operating charges for the two units, based on a population of 600,000, is $47,180, or at the rate of $1.573 per ton of rubbish handled.

The garbage reduction works, including loading stations, railroad sidings, power-line, etc., will cost $538,200 and the gross annual cost of operation of 600,000, will be $169,970.

In estimating the receipts from the reduction works at Toronto it is assumed that, with the naphtha process, the amount of grease recovered would be 3.5 per cent. and the dry tankage 15 per cent. of the weight of the garbage reduced and that grease would bring 3.5 cents per pound and tankage $7 per ton. On this basis the receipts from the sale of grease and tankage would be $210,000 per year giving a total net income of $40,030 annually, or 66.6 cents per ton of garbage.

Combining the estimates for the two incinerators and the reduction works, the construction costs for project C are $765,900 and the operating expenses $7,150 per year.

Project D.—This project is similar to project C except that the salable parts of the rubbish would be picked out and sold. The garbage, rubbish and ashes would be collected separately. The estimated daily average weights to be dealt with are garbage 200 tons, rubbish 100 tons, ashes 800 tons, the latter to be used entirely for fill. Of the total weight of rubbish only 67 tons would be burned in incinerators each day, the remainder being picked out and sold. Two 40-ton rubbish incinerators and one 240-ton reduction plant are recommended. The works are all practically a duplication of those described under project C.

The estimated cost of constructing the two 40-ton rubbish incinerators, including means for sorting out and handling

the salable part of the rubbish and including land, railroad sidings and paving is $2,555,300. The gross annual operating costs, including fixed charges and the cost of picking over the rubbish, is estimated at $92,510. The receipts from the salable material recovered, based on a value of $2.25 per ton of rubbish handled, would be $67,500 yearly, reducing the net cost of operation to $25,010 per year, or 83.4 cents per ton of rubbish handled.

The garbage reduction works and accessories are estimated at $538,200 for construction, and $169,970 gross for operation, the same as in project C. The estimated annual income from the sale of grease and tankage, however, is $210,000, leaving a net annual income of $40,030 for the reduction works.

Combining these estimates for the incinerators and reduction works the total cost for project C is $793,500 for construction, and with a population of 600,000 it is believed that there will be a net annual income of $15,020.

Summary.—After a discussion of the relative merits of the four projects Messrs. Hering & Gregory recommended that the refuse be separated into three parts, to be collected separately, that the garbage be taken to a reduction plant, located east of the city and converted into salable products, the rubbish to be taken to incinerators within the city and there burned, either without or with picking. It is also recommended that the ashes be taken to points within the city where land-making or road foundations are desired.

The report enumerates the important factors which lead to the final recommendations regarding the refuse disposal problem at Toronto. The first point has to do with the low-cost electric power from Niagara Falls. When the investigation was started it was the opinion, both of the local authorities and of Dr. Hering, that incineration of the city refuse would be the most probable solution and that works for this purpose would be required. With the advent of cheap hydro-electric power in Toronto the usual revenue to be expected from the sale of steam produced at incinerator plants can not be counted upon to reduce operating expenses. It would be cheaper at Toronto to allow the heat generated at incinerators to be wasted and to buy power from the hydro-electric company than to pay the cost of converting the heat into power. In view of these unusual local conditions the reduction process of garbage disposal comes prominently into the commercial foreground. The results obtained by the reduction process at Cleveland and Columbus are regarded as evidence of the satisfactory results obtainable from such works when properly operated.

The second important point bearing upon the recommendations is that the disposal of garbage, rubbish and ashes only is considered; other refuse, such as street sweepings, dead animals, etc., is disposed of satisfactorily by present methods.

The third consideration concerns the combined or mixed collection of refuse. The reduction process demands a separate collection of the several classes of refuse, and this is more costly than combined collection. The report advocates an investigation into the possible economies of collecting the refuse by electrically-propelled wagons receiving power from storage batteries.

The treatment of the refuse after delivery was the fourth important point. From the preceding figures of cost it is apparent that the projects for reducing the garbage and incinerating rubbish require a much greater outlay for construction than the projects for incineration of garbage, rubbish and ashes; the increase is $287,500 more without equipment for picking and $304,200 more with such equipment. The operating costs for the reduction projects, however, due to the return from the sale of products, is very much less, the difference being $117,790 per year without picking and $114,090 per year with pickings, assuming the population to be 600,000. Looking at the problem from the financial side, which it was the main object of the report to deal with, it appears that the reduction of the garbage is the most desirable means of disposal, although the necessity for separating the refuse is bound to cause inconvenience to the householder which a mixed collection would avoid.

WASTEFUL SYSTEMS OF SEWAGE PURIFICATION.

In a paper read before the Manchester Section of the Society of Chemical Industry, Dr. Grossmann stated that if all the valuable manurial constituents which are contained in sewage could be utilized on the land they would represent a value of somewhere about $200,000,000 a year. When the present system of sewage disposal by water carriage was adopted it was pointed out that it was the most wasteful system on economic grounds, but it was recognized that its advantages from a hygienic point of view should be such as to outweigh commercial considerations. The sewage, which is conducted by underground sewers to the sewage works to undergo further purification, consists of a liquid and a solid part, which are separated at the sewage works, and so far as the liquid part of the sewage (which ultimately finds its way into the rivers and the sea) is concerned, the present mode of purification, if properly carried out, will fulfil all anticipations with regard to public health; but as regards the solid part, the present mode of disposal is still a danger to the community. If that part which is generally termed "sludge" is carried out to sea there is a danger of infection to oysters, shell-fish, and fish; there is, moreover, a chance of this filthy material being washed back to places on the coast, as has been the case at several seaside places. If dumped on the ground it creates a nuisance, and if used on land for farming purposes there is the danger of infectious diseases being communicated to cattle and human beings from grass and crops grown on such land. Experiments carried out by the most eminent agriculturalists at the instigation of the Royal Commission on the treating of sewage and sewage sludge have conclusively proved that the value of sewage sludge, calculated on the dry substance which is contained in it, is no more than 10s. per ton at the outside, and as the sludge is produced at the sewage works in a state containing a large amount of water is cannot pay the farmers to use it unless the farms are in such close proximity to the sewage works that the cost of carriage and cartage is inconsiderable. Attempts have been made to reduce the cost of carriage by drying the sludge, but even after drying in the ordinary way it cannot be considered to be effectively sterilized, and is therefore still liable to carry infection. Moreover, it has been proved by the Royal Commission that it is worth even less after drying than before.

Dr. Grossmann gave calculations which showed the futility of attempting to dispose of the sludge by gasifying it in producers or of obtaining illuminating gas from it. The conclusions that he arrives at are that until the disposal of sludge is effected by sound hygienic methods there is still danger to the community; that no process for the disposal of sewage sludge can be considered satisfactory which does not enable us to return the manurial constituents contained in it to the soil in a thoroughly sterilized condition, and that sludge can never become a valuable manure unless it is previously freed from the greasy matters arising from soap suds and other fatty substances which in the sewers become mixed with the sludge, and which prevent its manurial constituents from being assimilated by the plants.

THE ECONOMIC ORGANIZATION AND MAINTENANCE OF THE FREIGHT CAR REPAIR YARD AT A TERMINAL POINT.*

By J. Thos. Warde.†

The question of the proper maintaining of a repair plant of where there is from two hundred to two hundred and fifty cars repaired daily, is a very serious one, and calls for careful consideration, to not only handle the work expeditiously but also to handle it in an economic manner.

To take the yard itself: Its location must be carefully selected; when possible, select a position where you can have twelve tracks of a capacity of twenty-five to thirty cars; tracks must be at least sixteen feet apart, alternate tracks, have a supply track of standard gauge and a third rail to form narrow gauge, and each end of yard should be connected by a lead. Yard must be well drained and, if possible, equipped with sewer and water system, compressed air system, electric power and light, and yard should also be in the near vicinity of shops as possible.

For buildings would recommend a central building under one roof, accessable from all parts of the yard, consisting of the foreman's office, general office, time office, stores, carpenters' shop, paint shop, oil house, triple rack, blacksmith and machine shop, men's lunch room and toilet, also lumber racks, material platforms and racks, and wheel tracks for B.O. and serviceable wheels. The advantage of one building lays in the fact of one heating; this can be very economically arranged for by an old boiler, and fed by the scrap wood, etc., this overcoming to a great extent the danger of fire, account of having stoves.

By having a drive-over about the centre of the yard and a standard gauge track, with a third rail making a narrow gauge track with turn-tables at intersects, you can connect all supply tracks—this can be used for handling wheels as well as other material, and also as a means of keeping yard clean of scrap, etc.

The fact of supplying a repair yard with a sufficient supply of necessary tools, quick lifting jacks, etc., and machinery should not be lost sight of, as (supposing yard is equipped and wired for electricity) individual electric motor power is not only economical, but desirable for the running of machinery. It will be found economy to install cut-off and rip saw, band saw, buzz planer, little giant borers, drills, portable forges and riveting hammers for steel car repairs, with a capable man in charge and helpers, blacksmith's forges with electric power fans.

Oil house should have (underground if possible) tanks. This point should have air device for emptying of oil barrels; should contain waste bin, oil tanks for soaking and proper treatment of, and making of dope.

Paint room should have a galvanized-iron covered table for cleaning of stencils, rack for storing stencils, iron tanks for paint, oil, etc.

The store room should be fitted with drawers, pigeonholes, racks, etc., for the proper storing of material and small supplies.

General office for use of assistant foreman, inspectors, clerks, etc., with a private office for foreman in charge. The efficiency of the organization depends on the executive and personal individuality of the foreman in charge; he should be a man of ability, an energetic nature and resourceful. His staff should average, for the number of cars mentioned: Six assistant foremen on a monthly salary, one inspector, four car oilers, thirty freight carpenters, one hundred and seventy car repairers, thirty laborers, two painters, two assistant painters, one clerk, two boys, one storeman, one leading laborer, two checkers, one leading air cleaner and tester, eight cleaners and two testers, and one pipe man and helper. The duties of the assistant foreman should be to oversee the work, under the general supervision of the foreman; these men should be taken from the rank and fyle, who have proved themselves adapted to the general overseeing of men and work; they should be practical and thoroughly conversant with the details of their work. The duties of the car inspector consists of inspecting all cars leaving yard; this man must be thoroughly conversant with the M.C.B. rules. Records of all foreign cars should be kept, re repairs. Repair and defect cards must be made and affixed according to M.C.B. rules. Duties of leading air brake tester: This man should have charge of air brake cleaner, testers and pipeman, and should be responsible, under the car inspector, for all air brake work. All triples should be cleaned and tested at the triple-rack, and a stock kept on hand for replacement. Duties of car oilers: It would be policy, although not recommended for a yard of this size, to have a leading car oiler; his duty would be to see that all dope is properly made, and a supply always on hand; he should inspect all boxes, and advise the oiler as to the re-packing. I recommend, in the matter of re-packing journal boxes, that a proper system be organized, and boxes re-packed and stenciled, and in the event of six months elapsing, pull box and renew packing, or, in other words, renew the packing every six months; packing removed to be treated and the oil and waste reclaimed. Two car checkers should be able to take record of repairs made to cars; same should be reported to foreman and fyled. Cars handled should be recorded by index system, and would recommend that a system be adopted to show time placed, time O.K., and dates; this can be handled by one of the boys. Carpenters and car repairers should be placed with assistant foreman as necessary, but recommend that any assistant foreman have not more than forty men. Painters should have well in hand the work of painting, etc.; all sheeting, roofing, etc., should be painted ready for use; the advantage in this is manifold, you have always something to keep your painters busy, your sheeting for patching is ready for the stencil, and finally your car is O.K.'d in one day instead of three. Laborers should be under charge of a leading-hand; his duties are manifold, from seeing that the scrap, etc., is gathered and placed in proper receptables to seeing material placed at stores, also heavy material placed in a convenient position to handle. The storeman should have charge of supplies, and be directly responsible for their up-keep. The foreman should furnish the general storekeeper every day a list of material supplied, attaching requisitions received and furnish a list of requirements. Foreman should be in close touch with stores and be in a position to anticipate requirements; this would be of mutual benefit both to storekeeper and himself. The clerk: I prefer training a man from the ranks of car repairers, as, being familiar with the work, he can handle the position to advantage. The foreman should insist on a careful record being kept of all work, supplies and general conditions, as the work of wrecking naturally falls to the repair yard, it is up to the foreman to insist on maintaining an efficient staff, and the wrecking crew should not be less than twenty men, taken from the car repairers; from these men selected at least two of them should be first aid men, holding certificates, and who have become conversant with the work; the men should be selected as required, according to nature of wreck; they should be under the charge of an assistant foreman, this man

*Paper delivered to Western Canada Railway Club, Winnipeg, Dec. 11th, 1911.

†Chief Clerk to General Car Foreman, Canadian Pacific Railway Co., Winnipeg.

should also be held directly responsible for everything in connection with wrecking work and the proper up-keep of the auxiliary equipment, and himself and crew be available day or night. One man should be assigned to the duty of factotum of the dining and sleeping car, and be able to satisfy the inner-man; his duties would also be that of commissary, which is no small part of the wrecking equipment.

The auxiliary equipment should consist of a serviceable dining and sleeping car (an old coach makes a good car) for this purpose, a tool car, heavy wrecking steam crane, block, tie and rail car, truck and wheel car. Tool car should be equipped with a first aid cabinet complete, with supplies and a modern equipment, quick lifting, traversing and other jacks, a plentiful supply of cables, tail ropes, chains and tools, and one man should be held responsible for their proper up-keep.

In arranging work for efficient handling on the repair tracks a set of rules governing proper marking of cars by inspectors in the traffic yards would aid repair yard men, and the rules of marking of cars should be respected by switchmen in placing cars on the repair tracks. Defects should be classed in A, B and C, or 1, 2 and 3 classes. Heavy work (three days) such as sills, roofs, etc., show A or "1" class; sill splices, ends, draught timbers, trucks, etc., medium work (two days) as class B or "2"; light, such as light patching, draught timber and gear bolts, brakes, side doors or any light work that can be handled in one day, show class C or "3." Tracks should be designated by the symbol or figure and cars placed as marked.

The foreman should place with yardmaster a switch list showing cars O.K. and location, listing cars he requires changed to other tracks to arrange his repairs, but the whole secret of success lies in co-operation with operating department in providing a proper and efficient system of switching.

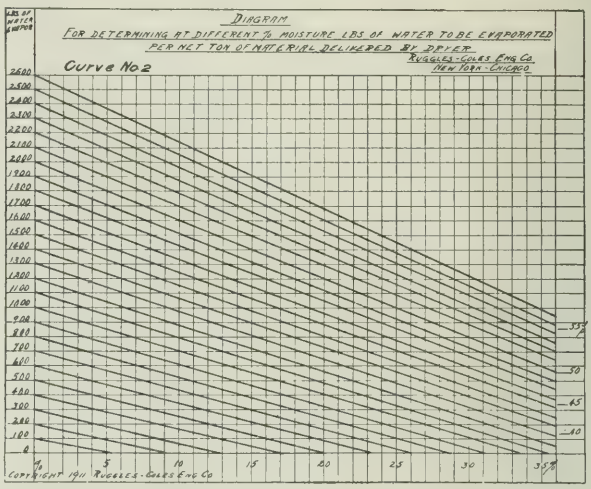
THE IMPORTANCE OF PERSONALLY STUDYING MIXER SPEED.

A great many contractors take the word of the operating engineer of the mixing plant as to results derived by increasing or decreasing the speed of the mixer drum, while for some unaccountable reason the latter seem unable to grasp the fundamental principles underlying the operation of a mixer for maximum capacity. A personal investigation by the contractor will often pay, as evidenced by the experience of Mr. A. W. Ransome, the well-known manufacturer of concrete mixers, who in a recent discussion stated that he visited a plant in which one of their 1-yd. mixers was being driven at eleven revolutions, and it required, at this speed, something over a minute and a half to discharge the bath. By speeding up to 19 r.p.m. the batch was discharged in less than 15 seconds.

Mr. Ransome stated that their machines are ordinarily sent out with the engine adjusted to give a mixer speed running from 16 to 20 r.p.m., depending on the size of the mixer involved. The speed for which the various machines are adjusted is that which will give the best results for the average material. The speed, however, is more or less subject to variation, according as the materials to be mixed vary and as the amount of water used in the mixing may vary. In other words, if the material flows very freely, the speed of the drum should be higher than if the material flows less readily, and, similarly, where a very wet mixture is used, the drum should be driven at higer speed than where the drier and more sticky mixture is handled. The real governing factor is to be found by looking in the drum opening and so adjusting the mixer speed as to get the maximum discharge into the discharge chute, instead of falling short thereof, or carrying over.

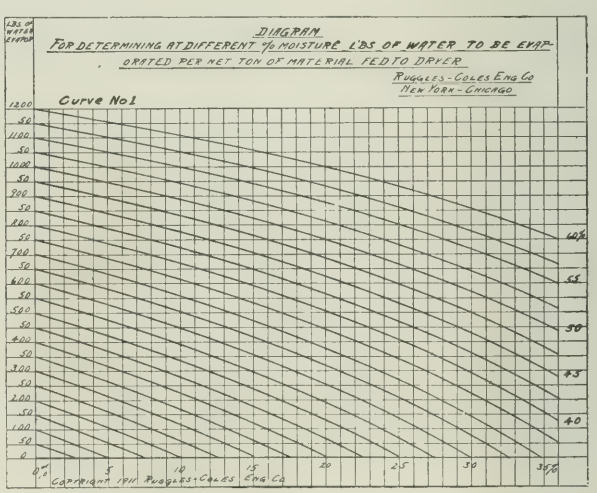
USEFUL CURVES IN DRYING CEMENT ROCK, CLAY, AND SIMILAR MATERIALS.

Cement companies use dryers for treating cement rock, clay, and other argillaceous materials as well as for drying the coal so that it may be pulverized and made ready for the kilns. The amount of water to be evaporated in reducing a given ton of material from one percentage of moisture to another is often desired to be known quickly. The curves



prepared by the engineering staff of the Ruggles-Coles Engineering Company fill this need and are reproduced here.

To make the use of these curves clear take a specific case of reducing cement rock from 6 per cent. moisture to 1 per cent. Referring to curve No. 2 follow the diagonal opposite to 6 per cent. at the bottom until it intersects the ordinate of 1 per cent. Then follow across to left and the figure 140 lbs. is the amount of water to be evaporated per



net ton of the cement rock delivered by dryer. Curve No. 1 is used in the same way and from it can be determined the lbs. of water to be evaporated per net ton of material fed to dryer.

A considerable saving of time can be effected by the use of these curves, and the Ruggles-Coles Engineering Co., 50 Church Street, New York, will send blue prints of them on request.

The Canadian Engineer

ESTABLISHED 1893.

ISSUED WEEKLY in the interests of the CIVIL, MECHANICAL, STRUCTURAL, ELECTRICAL, MARINE AND MINING ENGINEER, THE SURVEYOR, THE MANUFACTURER, AND THE CONTRACTOR.

THE TORONTO HYDRO-ELECTRIC COMMISSION.

The method of handling departments of municipal utilities by means of a commission has, during the past few years, received comment, both favorable and otherwise. There is little doubt that a commission composed of capable, energetic men is a most excellent instrument for directing and supervising the manifold items incidental to the carrying on of large undertakings. If a commission, however, is not well balanced and composed of individuals who have the time necessary to follow closely the daily routine, adjusting as occasion requires the small daily troubles that arise, and infusing into the work of the subordinates new vitality and enthusiasm, the work of such commission will not be the most efficient. Efficiency in these days of hurry is a prime requisite. The outlays of capital used in large constructional undertakings demand that work should be expedited as quickly as is consistent with a due regard for good construction, in order that interest charges may not accumulate, and that the period of income may quickly arrive.

The Toronto Hydro-Electric Commission was formed by act of the Ontario Provincial Legislature, and is composed of three men, one appointed by the Hydro-Electric Commission of Ontario, one by the city of Toronto, and the third the mayor of Toronto ex-officio. The work laid out for this commission is a large one, and it has only begun. Before it is finished there will have been a total expenditure of four and a half millions, of which only two millions have been already used. As we have noted in these columns before, the Toronto Hydro-Electric System has a strong competitor in the Toronto Electric Light Company. This company, with its affiliated interests, has the control of a large generating plant of its own at Niagara Falls, and it has its own transmission system. Its present heavy contracts with the Toronto Street Railway and other companies, place it in an enviable position for a strenuous fight. Every day the Toronto Electric Light Company is taking on new business which the Hydro-Electric, if it were in a better and more advanced position, could handle. Every contract the Hydro-Electric loses means a lengthening of the time before the system will be on a paying basis, which time must come before there is a lowering of rates.

The mayor is too busy a man to be saddled with the duties incidental to the work of the commission. Who would ask that the mayor be a member of the Harbor Commission or of the York County Good Roads Commission? Yet the duties of this body are far more onerous than either the Harbor or the Good Roads Commission. The mayor's duties are too many and too varied to force him to act on this body. Mayor Geary would be justified under the circumstances in withdrawing from the commission and appointing another who will devote his whole time to the work. By an amendment to the Act this could easily be done. Mayor Geary has proved himself in the past to be too broad and big a man to stand in the way of efficiency in the handling of the city's work, and we feel sure that sooner or later he will come to the conclusion that the interests of the city will be best served by an amendment to the Act as it now stands.

THE IMPORTANCE OF KNOWING COSTS.

The engineer of the present, to give the maximum of efficiency to his clients for expenditures on new work, must have a thorough knowledge, not only of the theoretic part of the design, but also of the methods of con-

struction necessary to give the minimum of cost. At the annual dinner of the Faculty of Applied Science and Engineering of the University of Toronto, on January 18th, Mr. W. F. Fye, the president-elect of the Canadian Society of Civil Engineers, laid special emphasis on the knowledge of costs in the experience of the engineer. Mr. Fye said that, to his mind, the most apt definition of engineering is "the art of doing well with one dollar what any person can do with two," and that it was impossible to do this without an intimate knowledge of costs and cost analysis. He would, therefore, advise the young engineer to keep records of the cost of the different works on which they are employed.

There is no question that this branch of the work of the engineer is exceedingly important, much more important than appears to be appreciated by many of the profession. Too often the question of costs is left entirely to the contractor who has the construction and installation of the work. But the engineer who superintends and lays out the work is negligent in his duty to his employer, and to his own best interests, if he does not keep in close touch with the costs of the different elements of the work. Much more necessary is it for him to have such knowledge if the consruction is being done by himself for his employer. For it is only by obtaining full information regarding costs that he can supervise intelligently. By a slight change in the method of arranging forms for concrete, by a different location for the concrete mixer, or in a hundred and one different ways he will find that he can save money and reduce the cost. There is another indirect effect which this study of costs has. The engineer who has constantly before him the aim of obtaining the most efficient results will not be led to needless outlay in the matter of design. He will study each element of the design in its relation to the purpose it must serve, and will choose the material which will do this as cheaply as possible.

The above statement is not intended as a plea for cheapess at the expense of efficiency or durability, but rather as a warning against the use of expensive and unnecessary details.

PER CAPITA ASSESSMENT.

The following table, which has been compiled by Mr. Samuel Baker, the city clerk of London, Ontario, presents in a clear manner the present standing of the ten largest cities in Ontario, as regards per capita assessment. It will be noted that the debenture debt per capita fluctuates within a wide range, from the figure of $45.93 for Windsor to the figure $182.98 for Fort William, although there is little difference in the population.

Per Capita Assessment.

City.	Population, 1911.	Municipal Taxes.	School Taxes.	Debenture Debt.
Toronto	341,991	$11.77	$4.59	$111.02
Ottawa	86,106	11.06	5.34	96.57
Hamilton	73,542	8.89	3.59	79.60
London	46,727	10.35	4.70	80.48
Brantford	21,964	10.05	3.73	90.17
Fort William .	19,858	12.44	5.75	182.98
Kingston	18,914	7.24	2.49	65.22
Windsor	17,534	10.16	4.63	45.93
Peterboro' ...	16,923	7.55	4.91	83.04
St. Thomas ...	15,240	7.77	3.52	61.78

One of the significant points of the table is the fact that Toronto, with the largest population, has also by far the largest debenture debt per capita, with the exception of Fort William. Evidently the citizens of Toronto showed good judgment in turning down the Tube by-law in the last municipal election.

Hamilton is to be congratulated on its showing as compared with the other cities of large population. When consideration is made of the large increase in population and area there in a comparatively short space of time, it reflects great credit on the city administration that they have been able to keep their debenture debt down.

EDITORIAL COMMENT.

In a recent newspaper report we note that Dr. McCullough, the Provincial Medical Health Officer for Ontario, has been on a tour of observation with Mr. N. J. Kerr, city engineer of Ottawa, looking over the different water filtration and sewage disposal plants of the United States preparatory to the installation of systems in Ottawa. If this is true it would appear that the Medical Health Officer is going afar afield of his duties. The plans which will be prepared for this work will, in the regular course of events, return to Dr. McCullough for acceptance before installation. He will then be put in the peculiar position of passing judgment on a scheme or design which he has already tacitly accepted while consulting with the city engineer. Ottawa may thus save the cost of paying for the services of a consulting engineer, but we do not believe that this means of doing so will meet with the approval of the engineering profession or of the public at large.

* * * *

Sir Hugh Allan, chairman of the Allan line, states that while he is very fearful of the practicability of a Canadian Lloyds, he would welcome it heartily. He believes, like many other Canadian shipowners, that the St. Lawrence route has been charged with many casualities which might fairly have been spread over other sections of the North Atlantic, and consequently the St. Lawrence vessels have been required to pay more than their full share. At the same time the rates of the English association has been on the whole both carefully and fairly made up. Mr. F. W. Cowie, the chief engineer of the Montreal harbor, states in an article published last week in The Canadian Engineer that during the season just closed only one marine accident of any importance happened in the St. Lawrence ship channel, when a large freight ship grounded and was released by tugs after lightening part of the cargo. This is certainly an enviable record.

LETTERS TO THE EDITOR.

The Editor:

Sir,—On about the fifteenth of October of last year, the building inspector of the city of Saskatoon ordered work stopped on two buildings known as the Willoughby and the Willoughby-Sumner blocks, on the grounds that the reinforced concrete structure was not sufficiently strong, for some unstated reason, either workmanship, materials or design. Work was suspended for about three weeks and then resumed on account of the building inspector having withdrawn his objection. In the meantime the report spread that the buildings were unsafe, and the writer, who happened to be away at the time,

heard of it in Winnipeg and St. Paul. The work was in charge of the Forest City Paving & Construction Co., and the architect W. W. LaChance, Esq., of Saskatoon. The reinforced concrete was designed by the writer, using twisted and round bars and following the specifications of the American Society of Civil Engineers. When the writer returned to Saskatoon he found that B. V. Hole, Esq., general manager of our company, had secured the services of W. R. Harris, C.E., M. Am. Soc. C.E , to superintend the making of tests on the buildings and that tests had already been made on the Willoughby building, and that same had proved satisfactory. Soon after, tests were also made on the Willoughby-Sumner building, which also proved satisfactory, and we enclose herewith a copy of the report by W. R. Harris, C.E., on these tests.

I might say that I am sending this letter to you at the suggestion of Geo. H. Archibald, Esq., contractor, Winnipeg, he having called the writer's attention to the fact that the reports circulated regarding these buildings had injured the standing of reinforced concrete construction in Western Canada, and that it was in the interest of the trade in general that a satisfactory explanation be made. The writer agrees with Mr. Archibald in this, and hopes you may see fiit to give this letter the publicity it may deserve. Yours very truly,

E. W. HYDE, JR.,

Manager Saskatoon Branch Forest City Paving & Construction Co.

Forest City Paving & Construction Co., Saskatoon, Sask.

Gentlemen,—I desire to report as follows, regarding examination and tests of two concrete buildings being constructed by you in this city:

On October 31st I examined the concrete and supervised the test loading of beams and floor slabs in the Willoughby building and found the concrete hard and sound.

Floor slabs and beams were subjected to a test load equal to 2½ times the estimated safe live load of 70 pounds per square foot, with a maximum deflection of ⅛ inch.

The deflection was normal and the examination and tests indicate that the structure is fully capable of serving the pupose for which it was designed and constructed.

On November 3rd the Willoughby-Sumner building was examined and tested, and in general the concrete was found to be hard and sound.

It was apparent that the concrete in this building was gaining additional strength with age, as is to be expected of concrete properly made.

All floor slabs and beams tested, except one, showed a normal deflection of ⅛ inch.

The one exception was a beam through which four electric conduits passed, the deflection on this beam was ¼ inch with a development of small cracks in tension side of beam.

This beam was not tested to destruction nor was permanent injury caused same by the test.

This building is capable of carrying the loads for which it was designed.

The first, second and third floors of the Willoughby building and the first and second floors of the Willoughby-Sumner building were tested; the remainder of the floors were not tested because a sufficient time had not elapsed since the floors were poured to justify such a severe test loading. Yours very truly,

(Sgd.) W. R. HARRIS, Saskatoon, Sask.

CANADA'S TRANSPORTATION PROBLEM.

BY E. B. BIGGAR.

Re-examining our economic relations to our fellow men and to the state, we find that out of what we produce —whether we are farmers, artisans, merchants or manufacturers—we pay toll or taxes mainly in two forms; first, on what we send out or take in from one place to another within our own country, and second, on what we import from other countries. The first we speak of as transportation charges, the second as customs duties. If we were born and educated in the planet Mars and dropped down upon the earth to investigate things anew, we would wonder why the second class of tolls upon our labor and income, though of minor consequence, is regarded as of the greatest political importance, while that which concerns each one of us most nearly, since it is an impost on everything we sell as well as everything we buy, is considered by many to be a matter almost outside the domain of politics. The readjustment of the customs tariff on an item that may add one dollar to the cost of a suit of clothes is a subject of such contention as may decide the fate of a government, but a railway official may, by a whim, or to meet an exigency, revise a schedule of rates which will add hundreds or thousands of dollars to the cost of our business, and the change seems to be accepted as a decree of fate.

Years before confederation became a practical issue in British America, a transcontinental railway under state control or ownership was advocated as a means of welding together the scattered groups of British colonies throughout the world, and so long ago as 1847 the prophetic vision of Major Carmichael Smyth saw in such a continental railway "a great link required to unite in one powerful chain the whole English race." There is the clearest proof that the need of a government owned transcontinental railway, both for imperial political purposes and for economic reasons, was felt long before there was a conviction in all the provinces that confederation itself was required. Antagonism to the confederation on political grounds lingered in some quarters long after the Act of Union came into force; while the warmest advocates of the measure found it necessary to acknowledge in a formal way in the terms of the union that, "the construction of the Intercolonial Railway is essential to the consolidation of the union of British North America and to the assent thereto of Nova Scotia and New Brunswick."

The Intercolonial Railway, however serviceable for local purposes, has always stopped short of that point where it could give to all the provinces the benefit of the lowest rates and best service from prairie to Canadian seaboard. For a time it ended at Riviere du Loup, then after a long delay at Quebec, and a still longer time elapsed before it reached Montreal; and all this time the railway traffic of Quebec and Ontario, and later on that of the new prairie regions, found its way to the sea, largely by way of Portland, Boston and other United States ports, instead of through the ports of the Maritime Provinces, which had paid for it by their assent to the union.

The high rates charged under the private ownership and control of the Canadian Pacific Railway have operated as a handicap alike upon the people of the West, and upon the fishermen, farmers, manufacturers and merchants of the Maritime Provinces—the former because prices have been depressed and the latter because the excessive tax of transportation cuts them off in competition with the producers and manufacturers of the middle western states, who ship to Canada at a cheaper rate. The same handicap operates against Ontario and Quebec.

Recent investigations of freight rates, passenger rates, express rates and telegraph rates, show that the cost of

transportation in the Canadian West is in excess of rates for corresponding distances in the United States by proportions ranging from ten per cent. to over one hundred per cent. This being the case, of what avail is it to the people of Canada to assist in building a second and a third transcontinental railway when there is no reduction of rates?

The Conservative government, which created the Canadian Pacific Railway, may have thought it provided a safeguard for the return of some of the enormous assets which it threw into the company's lap in money and lands when it stipulated that all profits in excess of ten per cent. should be returned to the people. But the company has found a way to mop up these extra profits by the creation of subsidiary companies, such as hotel companies, catering companies, land irrigation companies, etc.

To make a bad situation worse for the people who pay without control, the late Liberal government in subsidizing the second transcontinental system committed the people to an expenditure which it is said will reach $250,000,000, and has designed as far as it could, that that portion of the new system, which is owned by the private corporation and comprises the only profitable part of the road, should be exempt from the control of the government railway commission, while the portion in which there is no present possibility of profit is owned by the government and controlled by the commission.

It is true that there is a proviso in the Grand Trunk Pacific Act that the company shall not charge any higher rates to a Canadian sea port terminal than to a terminal in the United States. But to those who know the methods by which the Grand Trunk secures its present traffic from the West to its own terminal at Portland, and who know the plans now being matured at great expense for a second United States terminal at Providence, R.I., this provision will only give a light touch of comedy to the administrative tragedy of the late government. The appropriation of $30,000,000 to the Canadian Northern for its transcontinental road passed in the late Parliament almost without comment from either side, as the cold potato was handed to Rip Van Winkle.

Here we have government railways built at a cost to date of over $237,000,000, carefully held back from reaching the only regions of the country where promising traffic exists destined for the sea; while privately-owned railway corporations to which the Dominion and provincial governments and municipalities have given cash bonuses amounting to over $301,000,000, besides vastly more valuable lands, are levying upon the producers of the West a form of internal revenue tax which no people could possibly pay if it were not for the miraculous fertility of a virgin soil. Remembering that the Canadian railway companies are also the owners or controllers of the express and telegraph companies of the country, it is within the bounds of truth to say that these imposts when combined make a system of taxation upon the people unparalleled in any country pretending to modern civilization.

Seeing that the world's market prices are not fixed in Canada, foreign trade can only be gained by reducing the cost of transporting the products of the mid-continent to the Atlantic and Pacific. The control of rates, and ultimately the ownership of the transcontinental lines of communication, is the only means to this end, because the purpose of private ownership is to make profits out of its transport system, while government ownership, with the object of international trade would seek to render an efficient service at the lowest possible cost consistent with the payment of good wages. The excessive rates are undoubtedly the prime cause of the apparent difference in prices in favor of United States goods as compared with Canadian goods when laid down in the Canadian West.

Essentially the transportation of human beings and the materials of their sustenance and employment is of the same nature as the transmission of intelligence through the post, and as no statesman would now propose to hand back the postal service of a nation to private operators as once was the case, so the day is fast coming when the railway service of Canada must be under state operation.

The solution of the problem therefore is to prepare for the acquisition of the railway, express, telegraph, and long-distance telephone services, and as a preparatory step, to bring these present public service corporations under the authority of the railway commission which can be reorganized into branches to cope with its increased work. It may be that the railway companies will have the foresight to see that these changes must come, and the wisdom to accede in advance to a change to which they must otherwise yield under pressure of public opinion. Such a yielding is in fact now advocated by some of the ablest railway managers in the United States who recognize that the logic of the increasing control now exercised by the government over railway corporations is early government ownership.

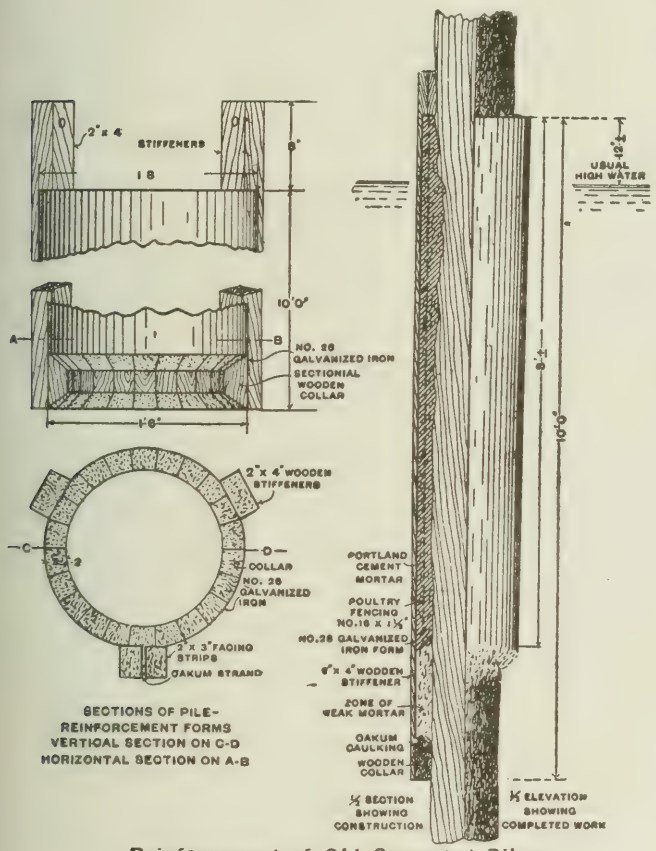
The Grand Trunk Pacific Railway should be expropriated by the Dominion government, and joined to the Intercolonial Railway, so as at once to afford an automatic regulator of rates from prairie to sea. That or the extension of the Intercolonial Railway to the Pacific. Some such method seems the only practical way of rendering long deferred justice to the people of the Maritime Provinces, the Western Provinces and British Columbia, and of securing to the nation what will inevitably be lost under the present scheme—the shipment by Canadian vessels and from Canadian sea ports of the produce of Canadian soil.

But where Canada has suffered and will suffer yet more in yielding up the principle of railway development on which our confederation was founded, is in the enormous and unreasoning waste of money, labor and land in the triplication of lines where communications already exist, to the starvation of those parts of the country that are without railway facilities. There is not even the consolation that a second or third line effects a material reduction in rates. For example, three competing lines of the three great corporations are now being finished between Toronto and Montreal, where one with new tracks to cope with increasing traffic would serve the public. The city terminal costs alone run into millions of dollars, not to consider the permanent waste of land by the extra right-of-way and the waste of labor by the triplication of the staffs. In the end the people, whose produce, labor and earnings provide this traffic—and who consequently suffer for this waste—are not benefited in the slightest by this illusory competition. What does the word "competition" signify when there is no reduction of rates?

But this is not the worst aspect of this senseless waste of a nation's resources. What was the purpose of the great sacrifices made by the people in subsidizing the private corporations to build these chains of communication? Was it not to colonize our vacant lands and utilize to the utmost benefit of all the provinces the resources of the country? Without doubt. And yet the primary purpose of each of our private railway corporations is to string their lines where traffic already exists, and new territory is now opened up only where profits are immediately visible. If colonization and the utmost public service were the actual, as well as the theoretical motive of railway building in this country, we should have in the older provinces lines to thousands of villages that are yet without access to railways, and still paying the oppressive cost of wagon haulage; while in the great West we should have had twice the area of land under cultivation with a doubling of the productive capacity of the country.

PILE PROTECTION.

In a paper read before the Boston Society of Civil Engineers, which is printed in the Journal of the Association of Engineering Societies, T. Howard Barnes described some wharf construction for the Guatemala Railway Company in Puerto Barrios, Guatemala, in which it became necessary to deal with some creosoted southern United States piles which had been in place for about seventeen years. These piles were nearly all of them in fair condition, excepting at and near the water line, but at this belt for, say, 5 ft. in width, most of them were badly eaten, many having cavities extending completely through them, resulting from the combined activity of the teredo and the limnoria. The expense of replacing these piles with new ones would approximate $50 each. The incentive for saving them by placing some reinforcement was so great that the writer gave much time to its consideration.



Reinforcement of Old Creosoted Piles.

The first idea was to place such reinforcement by using a chamber clam-shell like, each half of which should have a semi-circular opening in the parting line of the bottom for embracing the pile when clamped about it, and which would admit a workman after unwatering the chamber, the annual space about the pile being first calked. A test chamber was made, but trials in controlling it against the effect of even a wind-chopped sea of moderate force proved the futility of rapid and economical manipulation, and the idea of working in the dry was abandoned. Had the apparatus proved successful it was proposed to place a reinforcement of nails, poultry netting and cement mortar, similar to that hereinafter described for protecting some of the piles which were placed in the new construction.

Accordingly, forms were prepared for placing in the wet about the old piles a reinforced cement-mortar envelope which should have a width of about 8 ft. and a minimum thickness of 2 in. These forms were made of No. 26 gauge galvanized iron shaped into cylindrical shape with a slight taper and 10 ft. in length. A 2-in. x 3 in. strip of pine having a length of 8 in. greater than the form was attached on each side of the parting line, which was up and down. The metal was folded about the strip 1 in. on to the 3-in. side, leaving 2 in. for attaching an oakum strand, which was needed to prevent egress of mortar. Two 2-in. x 4-in. stiffeners of same length as the facing strips were fastened to the form at one-third points as shown in the cut. A collar of 2-in. stock made from narrow blocks was provided at the foot to serve as a gauge for regulating the thickness of the mortar, as well as serving to calk against in closing the foot against the escape of the mortar.

The mortar envelope was reinforced by a wrapping of poultry fencing of No. 16 gauge with 1½-in. mesh. The procedure was, first to scrape off the mussel growth on the pile to be treated. This growth forms a complete mat, but is detached quite readily. The poultry fencing was then put in place. This was made up into a roll, 8 ft. long, with sufficient fullness to lap on to itself several inches when placed about the pile. The form, nearly buoyant with the stiffners, was then floated into place, first having been provided with a wreath of fluffy oakum affixed to the collar. The facing strips were closed tightly with carriage clamps hung from them by cords of such length that when the clamps were squared into horizontal position they were in the proper place for screwing up by the divers. The divers were naked, and their further duties were to close the bottom of the form effectually against the egress of the mortar, watching carefully that none escaped at the time of the filling. Steel bars 8 ft long of ½-in. stock were hung, one in each of the three sections of the form. They had a shepherd's crook for support on the top edge of the form, and were used for slushing the mortar into compact state as it fills.

The mortar was made, one part cement to about two parts sand, the latter being silica and selected as coarse as possible, say 0.18 mm. effective size. It was assured that there was a little overfill of cement. The operation of filling was carried on rapidly, the effect of the slushing rods being supplemented by tapping with clubs on the stiffners, resulting in securing a sound mass excepting in the lower zone of about 18 in.

It will be noted that the forms were made 2 ft. longer than the reinforcement cage. The separating of the sand from the cement in the lower portion could not be avoided under the limitation of having to drop the mortar through so great a depth of water; accordingly the reinforcement was made to occupy only the sound part of the envelope.

Fig. 2 shows the construction and the finished appearance of the work. At the time of writing, the work is still in progress, with a record showing no failures. It should, however, be added that at times much delay is caused by difficulty in sealing the foot of the form. It is useless to place the mortar when any is escaping at the bottom.

The expense of this treatment is—labor (contract price), $8; materials (cement, fencing, etc.), $4; a total of $12, to which should be added the expense of experimenting and overhead charges.

There seems good reason to expect a further life of the piles thus treated as great as that at present sustained.

URGENT DEMAND FROM THE ADMIRALTY.

A Birmingham, England, firm of engineers have received an urgent order from the Admiralty for 150 sets of torpedo firing gear. The Admiralty have decided in this instance to forego the usual electrical tests in order that the appliances may be delivered at once.

CONTRACTS FOR THE SUPPLY OF ELECTRIC POWER FROM THE USER'S POINT OF VIEW.

IV.

By H. E. M. Kensit, M.I.E.E.

Further important points that should be clearly defined are:—

At exactly what point the power is to be delivered, and, if any transformation is required, exactly where the power is to be measured.

The following are sample clauses on these points:—

(1). "The supply shall be delivered at the pole nearest the reducing station of the consumer, situated on the consumer's property at ..... All energy shall be deemed to have been furnished when the power company has maintained the supply at that point."

It will be seen that this defines the point at which the supply is to be given, and provides that the consumer is to supply, and, presumably, to equip, the reducing or transforming station. It also leaves the consumer to bear the loss in transformers for reducing the pressure.

(2). "The power company will construct a line to convey the agreed amount of power to the customer's premises ready for distribution at approximately the voltage and periodicity set forth above."

(3). "The electric energy to be supplied under this contract shall be delivered to the customer at the terminals of the main outgoing switches in the sub-station of the power company, and the electrical equipment in the said sub-station shall be daily inspected by the electrician of the customer, and he shall immediately notify the power company of any defect in the same or detail requiring attention. Such inspection by the customer's electrician shall be deemed to be a voluntary aid to the power company, involving no responsibility to the customer beyond the use of reasonable diligence in making the aforesaid inspection and reporting the condition."

Here the expression "main outgoing switches in the sub-station of the power company" defines that the power company are to provide sub-station and equipment and bear the loss in transportation.

(4). "The electric energy shall be 3 phase, 60 cycles, 2,200 volts, and shall be delivered by the power company at the customer's sub-station and measured at the primary 2,200-volt switchboard of the customer."

Here it is clear that the customer receives the power at 2,200 volts in his own sub-station with the intention of further reducing the pressure at his own expense.

In some cases the customers provide the sub-station building because this cannot be removed by the power company at the termination of the contract, and the power company provide all the equipment for the sub-station, this equipment remaining their property. This is a fair and usually satisfactory arrangement. It then remains for the contract to specify clearly whether the power to be paid for is to be measured on the primary or secondary side of the thansformers. If not clearly specified, the power company will certainly measure it on the primary side, and the customer will, therefore, pay for the loss in the transformers. Either way is equally fair, as long as it is understood beforehand. The "all-day" loss in transformers may be from 3 to 15 per cent., depending on the size, and on the proportion of time during which they are fully loaded, working light, or merely wasting magnetizing current in order to keep them alive and ready for service.

The transformer loss is not usually an important matter where they are large and efficient, and where power is taken on the h.p. year basis, but it may be quite appreciable where the transformers are small, the energy paid for by the kw. hour, and the working hours a comparatively small proportion of the total time the transformers are in circuit.

To illustrate this, assume a factory with a total of 25 h.p. of motors installed. Taking 83 per cent. as the average efficiency of the motors, this corresponds to an input of 22.5 kw. Probably two transformers of 20 kw. each would be put in to avoid total stoppage from breakdown of one transformer; then either transformer could take the average load and the two together would handle any possible peak. This would mean a very small average load on the transformers and, therefore, a high percentage loss, so we will assume the more favorable case of one 25 kw. transformer, for the purpose of this example.

The efficiency of the transformer would usually be given by the makers about as follows:—

Full load.	¾ load.	½ load	¼ load.
98%	98%	97.8%	96.7%

so that the percentage loss at first sight appears small, but these figures do not represent the actual total annual cost of the loss in the transformers.

Assume the factory works 9 hours a day, 6 days a week, 300 days a year, then the total working hours per annum would be 2,700.

The **average** load of the factory, in most cases, would not exceed 40 per cent. of the rated h.p. of motors installed, so that in this case it would be 10 h.p. or 7.5 kw., which would be 30 per cent. of full load on the transformer. The transformer would, therefore, be working at an average efficiency of about 97 per cent.

The kw. hours used per annum would be 7.5 kw. × 2,700 hours = 20,250, so that the loss during **working** hours would be 3 per cent. of 20,250, which equals 608 kw. hours.

We have still to ascertain the loss incurred during non-working hours, which would be 8,760 hours per year, less 2,700, which equals 6060 hours. This is the loss due to keeping the transformers magnetized and ready for service, and after a year or two of use would not be likely to be less than 1¼ per cent.; 1¼ per cent. of 25 kw. for 6060 hours is 1894 kw. hours.

The total loss is, therefore, 608 kw. hours during working hours and 1,894 kw. hours during non-working hours, a total of 2,502 kw. hours, or over 12 per cent. of the total kw. hours used. In many cases the loss is undoubtedly greater, so that the question as to whether the power is to be measured on the primary or secondary side of the transformers is worthy of consideration.

It should, of course, in any case, be clearly specified that the power is to be measured after delivery on the customer's premises, unless it is specially desired to do otherwise, as in cases where the customer provides or finances the transmission line.

In some cases where the power company has to build a transmission line especially for one customer it charges interest on the amount so invested, but reserves the right to supply other customers from that line if the opportunity occurs. In this case the customer should be protected by a clause to the effect that if the line is used to supply other customers he shall thereafter only pay a proportionate amount of the interest.

CANADIAN MINERALS.

The annual report of the Mines branch of the Dominion Government shows the total value of mineral production in 1910 to be $105,000,000, an increase of $13,209,517, or over 14 per cent. Copper amounted in value to $7,209,463; gold, $10,224,910; pig iron, $11,245,630; lead, $1,237,032; nickel, $11,181,310; and silver, $17,106,604.

Correspondence and Discussion Invited

DESIGN OF OPEN-HEARTH FURNACES.

Prof. M. A. Pawloff, of St. Petersburgh, Russia, gives out the following data relative to open-hearth furnaces. The original paper appeared in the leading German paper, Stahlund Eisen.

1. Ordinary Gas Furnaces.—The dimensions are determined by: (1) the distance between the bulkheads = L, (2) the distance of the long sidewalls = E, and (3) the height of the roof above the bottom = ho. L × E may be called the bath surfaces.

1. Hearth.—Usually based on the weight of the charge T. The ratio of bath surface S to weight of charge T is not constant in the different furnaces, but decreases regularly with increasing capacity of the furnace. This ratio depends upon the depth of the bath (in Europe not over 300 mm., or 11⅜ in., and often less) and the furnace design. Table I. gives some ratios of modern basic open-hearth furnaces:

Table I.

Charge T Tons.	$\frac{S}{T}$ in Square Feet per Ton.	Path surface S, Square Feet.
12.5	12.9	161.5
15.	12.1	181.7
17.5	11.3	191.8
20.	10.76	215.3
25.	10.22	258.3
30.	9.68	290.6
40.	8.87	355.1
50.	8.61	430.4
60.	8.07	484.2

Sometimes we find $\frac{S}{T}$ somewhat greater, but rarely below above values. If the ratio $\frac{S}{T}$ has been well chosen, the most favorable value for T can be found only by practical experience under running conditions.

2. Dimensions of the Furnace.—The dimensions of the furnace are derived from the hearth. The width of the furnace in Europe is not over 11.5 ft., but in America it is as high as 14.8 ft.; the greatest length is 43 ft. The length of the furnace L may be found from the ratio $m = \frac{L}{E}$ after S has been chosen from Table I. In general m is between 2 and 3; in Europe usually 2½ or 2¾. For larger furnaces m = 3 is recommended. Therefore,

$$E = \frac{L}{m} \text{ and } S = L \times E = L \times \frac{L}{m}$$

$$L = \sqrt{S\,m} \text{ and } E = \frac{S}{L}$$

Table II.

Relation Between Capacity, Length and Width of Open-Hearth Furnaces.

T in Tons.	$\frac{L}{E} = m$	L Feet.	E Feet.	S Square Feet.
30.....	2.66	27.9	10.5	290.5
	2.70	28.	10.3	
40.....	2.70	31.	11.5	355.
	2.75	31.3	11.3	
50.....	2.75	34.4	12.5	430.
	2.80	36.1	11.9	
60.....	2.80	36.8	13.1	484
	3.00	38.1	12.7	

3. The slope toward the tapping hole is greatest in the middle of the hearth, being 1/12 to 1/16 of the width, in average 0.07, which corresponds to the tangens of an angle of 4°.

4. Furnace Volume.—The heights ho above the bath for 40-50-ton furnaces should not exceed 83 in. It depends largely upon the gas quality and quantity and the process in use for making steel. Only local conditions and furnace practice will decide this question, but it can be said that oil-fired furnaces require a greater distance than gas-fired furnaces.

5. Bulkheads.—The air inlet area is usually 23.25-38.75 sq. in. per ton of charged material.

The gas inlet area is 1⅓-2½ times smaller than above values.

The furnaces of the same system the area of the gas inlet decreases regularly with increasing furnace capacity.

	10-Tons Square Inch.	20-Tons Square Inch.	30-Tons Square Inch.	45-Tons Square Inch.	150-Tons Mixer Square Inch.
Air inlet	47.4	38.1	30.2	27.9	12.9
Gas inlet	39.1	29.8	23.6	18.6	7.8
Ratio	1.214	1.281	1.283	1.5	1.66

The reason for this is that the drop in gas pressure, caused by friction, is inversely proportional to the ratio of circumference to area.

Since the ratio $\frac{S}{T}$ decreases with increasing capacity, we may also compute the area of inlets from the ratio of this inlet area to bath surface. The author found that this ratio had an almost constant value, being 3.24 sq. in. for air inlet per square foot (or 225 sq. cm. per square meter).

6. Assuming the width of the inlets, the height is found from above data. The dimensions of the gas inlets are derived from those of the air openings. The author suggests that the ratio of the cross-sections of the air inlets and gas inlets should be proportional to the quantities of heat necessary for heating air and gas or to the quantities of the respective checkers.

7. Gas and Air Flues.—The slope of the gas flues (inlets) varies between 12° and 18°, and that of the air flues between 30° and 40°, and depends largely upon the size of the furnace. In American furnaces the gas burns almost completely, although only a single broa opening forms the gas inlet.

8. Vertical Flues.—Vertical flues have 25 per cent. greater area than their respective inlets for the larger furnaces, and 50 per cent. greater for the smaller (20-25-ton) furnaces.

9. Length of Bulkheads.—The length of bulkheads depends upon the type of the different furnaces. The distance between vertical gas flues and gas inlets is between 9.8 ft. and 13.1 ft.; for air flues the distance is between 4.9 ft. and 8.2 ft.

Regenerators.

10. Volume.—Modern practice per ton charge is 176.6 cu. ft. checkers for small European furnaces and 123.6 cu. ft. for the largest American furnaces. In economically working furnaces, which have a low temperature drop (about 120° C. or 216° Fahr. per hour) between two reversals, the author finds that there are 90 to 110 lb. checkers per pound of coal consumed per hour.

The author recommends to base the design of the checkers on the bath surface. By using the above values of the ratio S ÷ T, the checker volume per unit of hearth surface is almost constant = 4.5 cu. m. per square meter = 14.76 cu. ft. per square foot.

11. Dimensions of Regenerators.—The checkers in large furnaces are 80 per cent.; in smaller furnaces, 70 per cent. of the entire chamber volume. The depth of the checkers should not be less than 13 ft., and if possible 16 ft. The ratio between air and gas chambers varies between 2 and 1 For cool producer gas it is 1.5 and for hot gas 2; 1¾ being a fair average ratio.

Chimney Flues and Reversal Apparatus.—These dimensions are often too small, because in the case of rebuilding a furnace these parts are usually left unchanged.

12. In satisfactorily working furnaces the smallest area of air flue per 100 sq. ft. bath surface is 2 to 3 sq. ft.; the area in the reversal valves should be at least 3 sq. ft. per 100 sq. ft. hearth surface.

13. Instead of giving air and gas valve the same dimensions it is better to make the ratio of their cross-sections equal to the ratio of the cross-sections of their flues or to the ratio of their respective checker volumes.

14. Flues Between Valves and Chambers.—Flues between valves and chambers are made with twice the cross-section of the valve flue cross-section. Thus, for the air flue a cross-section of about 6 sq. ft. is chosen per 100 sq. ft. hearth surface.

15. Flues Between Valves and Stack.—The cross-sections of the flues between valves and stack should equal the sum of the cross-sections of the two flues which run to the valves of one side.

16. The same area has to be given to the stack at its base. The opening at the top of the stack is 1/20 S where S is the bath surface, making the diameter $d = \frac{\sqrt{S}}{4}$

The height of stacks should be 131 to 148 ft. for larger open-hearth furnaces.

II.—Oil-Fired Furnaces.—The ratio $\frac{T}{S}$ remains the same. The distance between roof and bath has to be greater to give the oil time for complete combustion; for 20-25-ton furnaces this height should be 71-79 in. The air inlet should be 4 sq. ft. per 100 sq. ft. hearth surface.

The volume of the air checkers should be 11.5 cu. ft. per square foot hearth surface, and on account of the high heat value about 140 to 160 lb. of checker should be used per pound of coal gasified per hour.

The cross-section of the flue to stack should be about 8.5 sq. ft. per 100 sq. ft. hearth furnace. The valve area and the opening of the stack at the top should be 4.25 sq. ft. per 100 sq. ft. surface.

THE ENDURANCE OF METALS.*

Experiments on Rotating Beams at University College, London.

By E. M. Eden (Armstrong College, Newcastle-on-Tyne), W. N. Rose and F. L. Cunningham.

When a piece of metal is subjected to alternating or intermittent stress the metal may fracture after a large number of alternations or repetitions of stress, although the maximum stress applied is considerably less than would be required to fracture the material with a single application. As in the large majority of cases metals used by engineers are subjected to varying stresses, and as failure when it does occur usually happens after a large number of repetitions of stress, the importance of tests on alternating stresses is very great. It is doubtful if a direct tensile test of a piece of steel gives any very definite information of its capacity to resist alternating stresses. The hard brittle-looking fracture of steel broken under repeated repetitions of stress is entirely different from the fracture caused by the single application of a larger stress in a testing-machine, and the hard-looking fracture of a broken piston-rod or crank-shaft is often taken as a proof that the material is or has grown too brittle for such service. The appearance of the fracture in such cases is probably responsible for the common idea that a soft ductile material is most suitable for withstanding alternating stresses.

The classical researches of Wöhler included experiments on repeated tensions varying from o to a maximum, repeated torsion, and on revolving bars subjected to a bending-moment while revolving; in this last case the stress in the outside fibres varies from a maximum tension to a maximum compression, and the range of stress is twice the maximum imposed stress. In every case the number of repetitions to cause fracture increases as the stress diminishes.

If a number of experiments with different maximum stresses applied are considered, and the applied stress is plotted against the number of repetitions to cause fracture, the points are found to lie more or less on a curve which appears to become nearly horizontal afer a few million repetitions. The stress where the curve is horizontal is the limiting stress which can cause fracture after an indefinite number of repetitions.

Culture, friendship and inspiration, these three, and the greatest of these is inspiration. This is the one thing which all the others lead to, for this is the true vision.

Tests were undertaken with a view to finding, if possible, the form of the stress-repetitions curve for any one material and to determine the effect of speed, or rate of alternation of stress on the stress-repetitions curve and on the limiting resistance for an indefinite number of repetitions. The testing-machine was specially designed and built with these objects in view, but the tests deal also with the comparative endurance of various materials and with the effect of rests, vibration, surface and form of test-piece, and annealing on endurance.

The testing-machine was of the revolving-beam type, in which the test specimens are subjected to a uniform bending-moment while revolving on their own axes. With truly turned test-pieces and holders the machine runs quietly.

The results of tensile tests of test-pieces cut from some of the bars of metal used for the endurance tests are shown in Table I. All the tensile tests were made on the full-size bar, and extensometer readings were taken on a 10-in. length.

*Abstract of paper read, October 20, before the Institution of Mechanical Engineers.

It is generally assumed that the stress-revolutions curve becomes horizontal after a sufficiently large number of repetitions of stress, and the ordinate of the curve where it is horizontal is the limiting stress causing fracture after an indefinite number of alternations or repetitions of stress. An examination of the curves which the authors give shows that this limiting stress is not reached with one million revolutions; this is seen more clearly in the logarithmic curves, which are also plotted, where, as in the case of the other curves, the limiting stress is the ordinate of the curve when it becomes horizontal. In spite of the irregularities in the position of the points, it seems to be certain that the curves have not become horizontal after one million revolutions.

Table I.

Bar No.	Material.	Limit of elasticity. Tons per sq. inch.	Tenacity. Tons per sq. inch.
5	½-inch bright drawn mild steel rod, Quality B	28.8	40.0
8	½-inch bright drawn mild steel rod, Quality A'	25.0	35.7
9	Vanadium steel Type A, oil-tempered	46.5	57.2
10	Vanadium steel Type A, annealed	26.8	38.4
23	½-inch blued rolled Bessemer steel, Quality D	35.7	49.3
25	3 per cent. nickel steel	44.6	57.0
26	25 per cent. special nickel steel	24.1	48.8
27	½-inch bright drawn wrought-iron rod	25.9	33.3
28	½-inch bright drawn wrought-iron rod	26.8	34.0
29	½-inch bright drawn wrought-iron rod	26.8	34.1

The limit of elasticity was obtained from extensometer readings, and is the limit of the straight portion of the stress-strain curve. Both the limit and tenacity are expressed in tons per square inch of original area.

TITANIUM IN RAILS.

A set of sections illustrating the wear of rails laid down on the Kessler's Curve in West Virginia, on the Baltimore and Ohio Railroad, have been issued by Messrs. T. Rowlands and Co., Stirling-chambers, Sheffield. The diagrams have been drawn out by Messrs. Robert W. Hunt and Co., New York, for the Titanium Alloy Manufacturing Company, Pittsburg, and deal with open-hearth and titanium-treated Bessemer rails. The curve on which these tests were made is one of 9 degrees, the superelevation of the outer rail being 6 in. 90-lb. rails were used. A previous test of ordinary Bessemer and titanium-Bessemer rails on this curve showed an improvement in favor of the latter of 294 per cent. In the present test, the difference in favor of the titanium rails is not so great. The test extended for 338 days, the loss being measured in square inches of sectional area. Of the rails on the inside of the track, the open-hearth rails averaged a loss of 0.250 sq. in., and the titanium rails as follows:—0.03 per cent. titanium, 0.273 sq. in.; 0.05 per cent. titanium, 0.169 sq. in.; 0.1 per cent. titanium, 0.155 sq. in.; 0.15 per cent. titanium, 0.147 sq. in. The wear was even all across the head, and the open-hearth rails thus showed 1.70 times the amount of loss of the 0.15 per cent. titanium rails. On the outer rails the wear was principally, of course, on the inside of the head, the wear being as follows:—Open-hearth, 0.36 sq. in.; 0.03 per cent. titanium, 0.428 sq. in.; 0.05 per cent. titanium, 0.39 sq. in.; 0.1 per cent. titanium, 0.389 sq. in.; 0.15 per cent. titanium, 0.273 sq. in. The ratio of wear of the open hearth to that of the 0.15 per cent. titanium rails is thus 1.32:1. The average ratio for the loss of all open-hearth rails to the 0.15 per cent. titanium rails, on both sides of the track, is 1.45:1. It may be added that the open-hearth rails were of 0.64 carbon steel, while the titanium Bessemer rails averaged 0.47 carbon. A test carried out some time ago on the Chicago, Burlington, and Quincy Railway, lasting for nine months and including nickel, maganese, plain open hearth, Bessemer, and two makes of titanium rails, showed that the titanium rails, of which the extra cost per ton is only about 2 dols., were equal to the nickel-steel rails, the extra cost of which per ton was no less than 40 dols., being, moreover, superior to the other makes covered by the test.

POWER REQUIRED FOR ROLLING MILLS.

Prof. M. Hermann (Stahl und Eisen) derives the following simple formulas from theoretical considerations and from a study of the recent investigations of Puppe. These formulas apply to the rolling of rectangular sections:

Let A = Reduction of sectional areas per pass, in sq. in.;
k = Limiting stress of lateral extension of metal, lb. per sq. in.;
t = Reduction of thickness of billet per pass, in inches.
D = Roll diameter, in inches;
v = Velocity of bar leaving rolls, ft. per sec.
a = Arc of contact of billet with the roll, in degrees.

Then,

$\cos a = 1-(t/D)$, from which sin a may be found from tables.

Force required to draw billet through the rolls: $F = 2k A$.

Roll pressure, in lb. $= P = k A [1+(1-\cos a)/2]/\sin a$.

H.P. (exclusive of power required to run rolls empty) $= F v [1.1+0.12 (P/F)]/550$.

The value of k is difficult to assign; it increases with the number of passes and decreases with increasing temperatures. Herr Hermann gives a table taken from Puppe's experiments in which k (average) for the 5th to 8th passes ranges from 6,940 lb. per sq. in at 2,237 deg. F. to 10,042 lb. per sq. in. at 2,091 deg. F.; and for the 9th to 17th passes from 7,965 lb. at 2,237 deg. F. to 11,547 lb. at 2,091 deg. F.; or mean values of k for the 12 passes ranging from 7,609 lb. at 2,237 deg. to 11,265 lb. at 2,091 deg.

Example.—Let A = 4 sq. in.; k = 8,000 lb. per sq. in.; t = 0.75 in.; D = 20 in.; v = 6 ft. per sec.

Then,

$\cos a = 1-(0.75/20) = 0.9625$. whence $\sin a = 0.2712$.

$F = 2 \times 8000 \times 4 = 64{,}000$ lb.

$P = 4 \times 8000 [1+(1-0.9625)/2] \div 0.2712 = 120{,}206$ lb.;

$P/F = 1.8782$.

H.P. $64000 \times [11.6+(0.12 \times 1.8728)] \div 550 = 925$.

HYDRO-ELECTRIC POWER IN CHILE.

It is proposed, in a report submitted to the Chilean Ministry of Industry and Public Works, to divide the hydraulic works department into sections—(1) hydraulic surveys (2) power stations (3) transmission of electric energy; to expropriate as soon as possible all the hydraulic undertakings which it may be thought desirable to be worked by the State; and to encourage the development of other hydraulic projects by private enterprise in the most efficient manner. It is also proposed to investigate the requirements of the State railways, and the possibility of employing hydro-electric power for military and naval arsenals. The first part of the programme will comprise inquiries to be made during a period of five years in connection with the rivers Aconcagua, Maipo, Cochapoal and Bio-Bio.

ENGINEERS' LIBRARY

Any book reviewed in these columns may be obtained through the Book Department of The Canadian Engineer.

BOOK REVIEWS.

The Theory and Practice of Technical Writing. By Samuel Chandler Earle, Professor of English in the Engineering School, Tufts College. The Macmillan Company, New York and Toronto, Canada. Cloth; 5x7½ ins.; pp. 301; many text illustrations. $1.25 net.

The present tendency in the engineering schools is to devote more time to the study of English. It is only recently, however, that such instruction has been given. This instruction has varied in different schools, and falls into two general classes. The first class is that in which English is taught as a purely cultural part of the curriculum. This teaching is often given with the other students taking a general arts course. Many of the schools in the United States, however, have given separate instruction to the engineering students, and as a result there has developed a course of lectures specially adapted to their needs. This has naturally led to a specialization of the teaching of English, which may be called technical English, and this is the second class. The command of good technical English is as essential to the engineer as the other elements of knowledge which go to make up the well balanced man. This is coming to be appreciated more and more. Few of the engineering schools do not now give instruction along these lines.. Therefore any book dealing with the subject of technical writing is of interest from this point of view.

However, this book by Professor Earle is of interest to more than the engineering student or the teacher. Professor Earle draws attention to the fact that the engineer makes use of a form of expression no less special than that of the lawyer, the novelist, or the poet; and the engineer no less than the members of the other professions, needs special training in writing, over and above all that he may get in general composition. In this volume a study of some of the fundamental problems of technical writing is given in an accurately, orderly and logical sequence.

The book will be of service to the student as an introduction to technical writing, and to the engineer of some years' standing, as a concise presentation of what he perhaps already appreciates in a general way.

Theory and Practice in Designing. By Henry Adams. Published by Constable & Company, London. Cloth; 5¾ x 8¾ in.; 240 pp., including index; 371 illustrations. Price $2 net.

The author has written many books on designing, but this one is quite distinct from the others. In this treatise the theory of structures is dealt with, from the most elementary examples of simple beams and columns, to the more involved cases of trusses, continuous girders, arches and suspension types. Elementary mathematics are used throughout, and graphic status are used wherever possible.

The subject matter taken up includes safe loads, stresses in different structures, bending moments, moments of inertia, foundations, riveting, designing of girders, trusses, roof trusses, columns, cantilevers, suspension bridges, arches and retaining walls. In fact, the subjects covered are too numerous to allow of very extensive treatment in the book; for this reason formulae are given without their theoretic analysis and basis. There are many valuable details given throughout the volume which will appeal to the young designer. The different elements of design are illustrated by examples which are worked out arithmetically.

The book appeals more to the draughtsman and designer who has not had the advantage of a course in a technical college, and who is without a knowledge of higher mathematics. To such a man the book will be valuable. It should also be useful to the architect and structural engineer. It, however, would have been better to have omitted on the other hand the inclusion of such matter as the elementary principles of trigonometry, and at the extreme, the treatment of arches and suspension bridges. This constitutes the objection to the book in that the attempt is made for too broad a treatment of the subject of design of structures.

Aside from the above mentioned objection, the book will be found to be a useful one.

Structural Engineering. By Joseph Husband and William Harby. Publishers: Longmans, Green & Co., London. Cloth; 6x9 in.; 396 pp.; 32 tables; 337 cuts. Price $2.50.

Books on structural engineering fall usually into two classes: those which treat the subject from a purely theoretical standpoint and those which deal mainly with regard to the practical arrangement of structural details. Between the theoretical analysis of stresses and loads and their application to a practical design there exists a gap which, in the literature existing at the present time on the subject, is not very well bridged. In this volume the endeavor is made to combine these two divisions, treating the theoretical side of the design first and leading up to the practical application to the actual incorporation in the structure of the different elements composing the finished work. The mistake so often made in volumes treating technical subjects, of endeavoring to cover too wide a field, has been avoided, by confining the consideration to simple structures and details of everyday occurrences. This principle could have been carried to advantage even further by omitting a chapter on the materials of construction. The book is well arranged, leading logically from loads and stresses, bending moments and sheering forces to the elements making up the structure, such as beams, columns and struts, plate girders and lattice girders; then follow chapters on deflections, roofs, miscellaneous applications and tall buildings and masonry and masonry structures.

The chapter on columns and struts is very good, covering the different formulae in use, noting their applications and restrictions, and giving many numerical examples when applied to actual design.

The book is a decide d addition to the literature of the subject and should prove of general utility to the student and draughtsman having occasion to make use of it.

Home Waterworks. By Carleton J. Lynde. Published by Sturgis & Walton Company, 31 East 27th Street, New York. Size, 5x7. Pages, 280; illustrated. Price 75c. net.

The obtaining and introduction of water into houses and outbuildings, and the domestic utilization of water-power are

the subjects treated in this volume. This thoroughly practical book meets a widely recognized need for information, and is written by a specialist.

Thousands of men living in rural parts of Canada, out of reach of a public water system, have equipped their homes with water supply conveniences equal to any found in the cities. Thousands more who could well afford to do so and who could do so advantageously, have not done so for various reasons—because the idea has not occurred to them, or because they did not know how to go about it, or because they mistakenly thought the expense too great. To all such this book should prove of the greatest practical help.

The author of the book is Professor C. J. Lynde, of Macdonald College, Quebec, and the book contains chapters on the value of water indoors; first steps in kitchen equipment; sources of water supply—underground water; sources of water supply—wells and their requirements; sources of water supply—springs, rivers, lakes, and cisterns; properties of air supplied in pumps; pumps and their action; standard types of pumps; running water—the pneumatic tank; the siphon—the hydrostatic paradox—the kinetic theory; methods of pumping—hand power, horse-power and windmills; methods of pumping—the hydraulic ram; methods of pumping—the hot-air engine; method of pumping—the gasoline engine and steam engine; method of pumping—the electric motor; water power; plumbing and sewage disposal; acknowledgment; firms dealing in water supply and plumbing materials.

In addition to a table of contents there is an index well arranged and complete.

The book is interestingly written, and is correct as to statements, and is not so technical that it confuses. Being a manual of water supply in country homes, it is written more for the general reader than the engineer, yet the engineer will find much of interest.

The Canadian Almanac. Published by Copp-Clark Company, Toronto. Paper; 6 × 8¾ in.; pp. 504. Price, 60c. net.

This volume is now in its sixty-fifth year of publication. Every editor has seen additions and improvements rendering it more convenient and complete and ready of reference. The result of this continuous attention is exhibited in the numerous lists and pages of information not found elsewhere and presented in a way that saves much expenditure of time and pains. The publishers justly claim that in no other volume can so much information about Canada be found in so small a space. Among the principal subjects covered are the astronomical and tide tables; the complete customs tariff; weights and measures and foreign exchange. The banks, branches and names of managers are given; patents in Canada receive attention, and a full Canadian militia list is included. Complete post and postal information and newspaper statistics; particulars regarding the Dominion and Provincial Governments, the clergy of all denominations, the legal profession, educational institutions, life assurance companies and other societies are all to be found within its boards. This edition also includes maps of Manitoba, Alberta and Saskatchewan, showing railways and principal towns. The volume is clearly printed and is in every way a credit to its publishers.

Mechanics of Materials. By Professor Louis A. Martin. Published by Wiley & Sons, New York. Renouf Company, Montreal, Canadian agents. No. of pages 210; size 7½ × 5½. Price, $1.50.

Professor John Perry, speaking of the use of the mathematics by students, somewhere asserts that although they may be able to pass difficult examinations in the calculus, and to differentiate any function of x and to integrate many, their mathematical knowledge seems to be of no use to them in practical engineering problems. Professor Martin, in his academic work has evidently realized the same difficulty, for in "Mechanics of Materials" his method of treatment has been manifestly designed to encourage the student to apply his mathematical tools.

The little volume bearing the above name is the third of a series in uniform size, type and binding, issued by Professor Louis Martin, of Stevens Institute. Like its predecessors, it claims to be a text-book rather than a treatise and in this instance covers the work usually taught in schools of engineering as an introduction to structural and mechanical design. The work presupposes a knowledge of the conics and of the infinitesimal calculus as a preparation on the part of the student, and as stated above, the use of the latter in the derivation of formulae and the solution of problems is frequently made.

The volume devotes a chapter to stress and strain, and Hooke's law and proceeds at once to the theory of the beam. Of its two hundred pages over eighty are devoted to this element, and in consequence the treatment is quite as full as one would expect in a volume of its scope. The author in this connection develops in conjunction with, and by the aid of, graphics, the principle that the Moment, Shear and Load diagrams are derivative curves; that is, that the shear is the first derivative of moment, and method of loading the second, with respect to axial distance. This view will be instructive to students who have been previously trained to regard, for example, velocity and acceleration as the first and second derivatives of space with respect to time, and the one will undoubtedly elucidate the other.

Subsequent chapters are devoted to columns and struts, torsion in shafts, thin and thick cylinders under internal pressure, an introduction to the mathematical theory of elasticity and what in the texts is commonly known as compound stress. The writer is not quite clear why no reference is made to riveted joints.

The volume has much to commend it. The graphics are good, as is also the selection of problems, 276 in all, illustrating applications of the theories discussed. For these, the answers are appended, providing a source of much satisfaction to the conscientious students. A perusal of them shows, also, that the author is not merely an academician. The book will be read with profit by both teachers and students of the subject.—P. G.

Analytical Mechanics. By Professor Edwin Barton, University College, Nottingham. Published by Longmans, Green & Company; 525 pp.; 6 × 8¾. Price, $3.

This book differs from many recent texts for the use of students of mechanics in the extent of the field it covers. The tendency toward extreme differentiation in the teaching of science and the compilation of texts is evidently not regarded sympathetically by Professor Barton, for the excellently thorough work at hand discusses in turn Kinematics, Dynamics, Statics, Hydromechanics and Elasticity—subjects to each of which the modern tendency is to denote an entire volume. To read it intelligently, the student should possess a working knowledge of the differential and integral calculus and of differential equations, so that the text can scarcely be described as elementary. In fact the volume is manifestly intended more for the student of Pure than of Applied Mechanics, in that the exemplification of principles is rather more academic than practical, yet, notwithstanding this, it will be generally conceded that a knowledge of its contents would be of inestimable value to the student contemplating the study of engineering science. Occasional reference, his-

torical and otherwise, is made to the classics of Galileo, Newton, Thomson and Tait, Gauss, Lodge and others, but as to the controversial questions concerning the philosophical basis of the science, the author displays a commendable toleration. The large collection of selected problems is an excellent feature of the book, whose usefulness would undoubtedly have been somewhat increased had the answe s to these been appended. In contrast with some of the texts that have appeared during recent years, especially from the American press, this volume displays discrimination in the compilation of matter, system in its arrangement, and care in its editiing, and on the part of the author, capacity and thoroughness. The book will constitute a real addition to the literature of this subject.—P. G.

Practical Cement Work. By W. B. Henry. Published by The Concrete Age Publishing Company, Atlanta, Ga. Size, 4 x 6½ in.; pp. 110. Price, 50c.

A practical little book on cement construction, which will be of interest to any one identified with the cement or building industry. The book contains short chapters on the materials of concrete and its use in construction.

Modern American Telephony. By Arthur Beasey Smith. Published by Frederick J. Drake & Company, Chicago, Ill. Size, 4½ x 7; leather bound; 790 pages, including index; 470 illustrations. Price $2.

This book is a treatise on Telephony in all its branches, compiled and edited by Mr. Smith. It includes descriptions of the installation, operation and maintenance of telephones, with a description of the different systems, chapters on power plants, different types of switchboards, protective devices, measuring instruments, line construction, etc. This is a book for the telephone engineer and the workers on telephone switchboards.

Ship Wiring and Fitting. By T. M. Johnston. Published by Constable & Co., Ltd., London. Cloth; size, 4¼ x 6½; 77 pages; illustrated. Price, 50c.

This book is intended to treat in a simple manner the systems of wiring most commonly used in the fitting of electrical apparatus on vessels of the mercantile class. The different adverse conditions which have to be contended with in installing electrical apparatus and the precautions necessary for safeguarding the efficiency of the work are discussed. The book is a concise treatise on the subject, and forms one of the electrical installation manuals issued by the publishers.

The Waterpowers of Canada. Issued by the Commission of Conservation, Canada, James White, Secretary. Authors, Leo. G. Denis and Arthur V. White. Cloth, 7 x 10 in., 397 pp.; well illustrated.

The first inventory ever taken of the water-powers of Canada has been completed by the Commission of Conservation and the results embodied in a large and profusely illustrated report just issued. The investigation made by the Commission, which has extended over a period of two years shows that there are 1,016,521 horse-power developed from water-power in Canada. Every phase of the subject from the laws governing the disposition of water-powers in the various provinces, to the actual physical data regarding each individual water-power concerning which information was obtainable, is treated in the report. In addition, there is a very full bibliography of 30 pages, and the appendices giving, among other things, the text of the laws concerning the export of power and also of the treaty recently concluded with the United States regarding the establishment of an International Joint Commission.

The volume opens with two chapters of an introductory nature that are concerned mainly with the general economic bearing of water-powers on national development. The relation of water to agriculture, mining, navigation, domestic supply and so forth, is dealt with, and the principles to be used in the interpretation of water-powers data are stated and discussed critically. The broad and optimistic statements very often made on the platform and in the press regarding our vast water-power resources are deprecated. To quote from the Report, "General statements implying that the aggregate amount of water-power must be great because the total water area, or watershed area is so great, or because there are so many lakes and rivers, are generalities to be considered of very little definite value . . . One of the chief dangers of such generalities is to create in the popular mind a feeling of unwarranted assurance that, even though desirable water-rights are being granted by a government, yet there is so much left that no apprehension may be entertained regarding the amount of power rights being parted with."

A chapter is devoted to the water-powers of each province in which the general features of the province as regards water-power development are discussed and an outline given of the law whereby powers are granted or leased to private individuals or corporations. The larger developments are also described. The statistical data given in tabular form includes the height of the fall, the horse-power that may be developed, the present development and the main uses to which the power is applied such as lighting, pulp and paper making, etc. Reference is also made to the possibility of increasing the amount of power developed by storage reservoirs and dams where such are feasible.

The power situation in Ontario is treated very fully, special attention being given to the power possibilities at Niagara and the conditions affecting development there. Each of the power companies operating there, whether on the Canadian or American side, is described in detail. A significant reference is made to the granting of franchises to develop power at Niagara Falls. The report states that the low-water flow of the Niagara river would yield at the Falls, about 2,250,000 H.P., of which Canada's share (one-half), would be 1,125,000 H.P. "Franchises have already been granted," it goes on to say, "and plants partially completed, for the development on the Canadian side of the river, of about 450,000 H.P. In other words, instead of 'millions' of horse-power being available, as has been sometimes stated, it appears that about half, and by all odds the better half, of Canada's usable share of Niagara Falls power has already been placed under private control."

The volume embodies all the useful information regarding the water-powers of Canada that has heretofore been collected and this has been supplemented and, in many cases, verified, by field surveys, conducted by the engineers of the Commission. In fact, all the information regarding the Maritime Provinces powers was obtained in this way last year by the experts of the Commission. The data regarding the Western Provinces was found to be so incomplete that it was decided to make special investigations of the powers in those Provinces, the results of which will be published next year in the form of a report on the "Water-Powers of Western Canada." The engineers of the Commission are now engaged upon this work.

PUBLICATIONS RECEIVED.

Publications of the Canada Department of Mines, Mines Branch. The production of cement, lime, clay products, stone and other structural materials in Canada during the calendar year 1910.

The Production of Coal and Coke in Canada during the year 1910.

The Production of Iron and Steel in Canada in the year 1910.

A general summary of the mineral production of Canada during the year 1910.

The above four pamphlets are edited by John McLeish, chief of the division of mineral resources and statistics.

Geological Surveys Branch. The Bighorn Coal Basin, Alberta. Memoir No. 9E; by G. S. Malloch.

The Clay and Shale Deposits of Nova Scotia and portions of New Brunswick. Memoir, No. 16E; by Heinrich Ries, assisted by Joseph Keele.

Report of the Department of Naval Service for the year ending March 31st, 1911. Price 10c.

Forty-fourth annual report of the Department of Marine and Fisheries, 1910 and 1911. Price 30c.

Bulletin No. 229. Olive Oil, issued by the Laboratory of the Inland Revenue Department, Ottawa, Canada.

Bulletin No. 227. Fertilizers; Laboratory of the Inland Revenue Department, Ottawa, Canada.

Avalanches and Forest Cover in the Northern Cascades; by Thornton T. Munger. Circular No. 173, Forest Service, United States Department of Agriculture, Washington, D.C.

The Year Book of British Columbia, 1911. Issued by the Government of British Columbia; bound in red cloth and containing a manual of provincial information. Copies of the Year-Book may be obtained at $1.15 per copy by applying to the King's Printers, Victoria, B.C.

Report of Proceedings of American Mining Congress. Fourteenth annual session held in Chicago, Ill., October 24th to 28th, 1911. Published by the American Mining Congress at the office of the Secretary, Denver, Col.

The Concrete Institute. Transactions and Notes. Vol. III. Published November, 1911, at the offices of the Concrete Institute, Denison House, 296 Vauxhall Bridge Road, Westminster, England.

Factories and Warehouses of Concrete. Published by the Association of American Portland Cement Manufacturers, Philadelphia, Pa. Price 50c. Part of this volume was published in a recent issue of The Canadian Engineer. The Canada Cement Company, of Montreal, have ordered a number of these books and will send them out free to architects, engineers and manufacturers, except for the cost of mailing, which will amount to 12 cents. Copies may be secured from L. S. Brunner, manager of publicity, Canada Cement Company, National Bank Building, Montreal.

Saxon Portland Cement Company Diary. A diary for 1912 issued by the Saxon-Portland Cement Company, of Cambridge. Bound in a very artistic manner with padded blue cover. Copies may be had from the Saxon Portland Cement Company, Cambridge.

CATALOGUES RECEIVED.

Scraper Bucket Excavators. Pamphlet No. 427; issued by the H. Channon Company, Chicago, Ill., illustrating different types of their scraper bucket excavators. A very handsome catalogue.

Automatic Sprinkler Bulletin. Issued by the General Fire Extinguisher Company, New York, January, 1912.

Continuous Feed Bronzing Machine. Pamphlet illustrating the Kolboch Flat Continuous Feed Bronzing Machine. United States representatives, C. B. Henschel Manufacturing Company, Milwaukee, Wis.

Carbonizing Coating. Pamphlet issued by the Goheen Manufacturing Company; illustrating different works on which their carbonizing coating for the preservation of steel has been used.

Compressors. Bulletins 34A, C. E. and H, issued by the Chicago Pneumatic Tool Company, illustrating different types of their steam-driven and gasoline-driven compressors, with instructions for installing and operating. Offices, Fischer Building, Chicago; 50 Church Street, New York.

Air Compressor. Folder issued by Canadian Rand Company, Commercial Union Building, Montreal, illustrating the Rand Class "C2" compound straight line, steam-driven air compressors.

"SKF Radial Bearings" is the title of a bulletin just issued by the S.K.F. Ball Bearing Company., 50 Church St., New York. This bulletin explains the construction peculiarities, particularly the provision of self-alignment, of SKF Radial Bearings, and gives dimensions, speeds and capacities of the principal types and sizes.

Boiler Tools. An illustrated folder showing the Faessler octagonal sectional expanders, roller expanders, and flue cutting machine. Return post card attached. J. Faessler Manufacturing Company, Moberly, Mo.

Sewage Lifting Apparatus. "The Priestman Ejector System" and "Progress in Sewage Treatment No. 7" have just been issued by Merritt & Company, Camden, N.J., and deal mainly with the Priestman Ejector System and the subject of Sewage Pumping. "The Priestman Ejector System" is in the form of a proposition containing 14 pages, size 8½ × 11, and takes up first the various applications of the Priestman hydro-pneumatic ejector, as for instance, in parts of a sewer system at sewage purification works, or for the basement of deep buildings. These applications are discussed at further length after a page devoted to a concise description of how a Priestman Ejector operates without any moving parts in contact with the sewage and how the compressed air is made to work expansively for discharging sewage. In subsequent pages the various advantages of this type of sewage pumping apparatus are given, and also details regarding its construction. A table of standard types covering capacities from 5-2000 G.P.M. and tables giving the dimensions of standard ejectors of both the vertical type and hemispherical type are then given. Standard dimensions of the horizontal type are not included since, as it is stated, the design and installation of horizontal ejectors depends upon local conditions. Ejectors of this type are used where the amount of head room available is very limited. The last two pages comprise data sheets which outline the figures which are necessary for proper recommendation of the ejector systems in basements of deep buildings or for city pumping stations.

The second publication "Progress in Sewage Treatment No. 7" is a technical paper, size 6 × 9, 24 pages, 18 of which are devoted to articles, 3 to editorial matter and 3 to advertisements. The leading article is from a report by Mr. Geo. T. Hammond, M. Am. Soc. C.E., and is entitled "Automatic Sewage Lifting Station Equipment." It analyzes the various advantages of the centrifugal pump and the compressed air ejector, pointing out among other facts that "the pneumatic ejector is an especially satisfactory means of lifting sewage wherever a reliable apparatus is desired for handling a small quantity of flow, or a considerable quantity coming to the plant in a variable amount. The centrifugal pump works best where the flow is quite constant and of considerable quantity."

Several valuable tables are given, as for instance the average efficiency of centrifugal pumps and of compressed air in pneumatic ejectors. Following Mr. Hammond's article, some six pages are devoted to an article on pneumatic ejectors abstracted from the Surveyor, London, and another describing the sewage ejectors at the Pennsylvania Station,

N.Y. The eighteen Priestman Ejectors in use at this plant handle a flow of sewage equivalent to that which would be contributed by a city of 40,000 inhabitants.

In the editorial section a page is devoted to the Water Waste at Memphis, by flush tanks, and another to the subject of Mr. Hammond's paper. Particular reference is made to the table of efficiency of compressed air in ejectors, and a note is given covering the equations for adiabatic air compression.

Both of these publications, i.e., "Progress in Sewage Treatment No. 7," as well as "The Priestman Ejector System" are for general distribution, and will be sent upon application to the Hydraulics Department, Merritt & Company, Camden, N.J.

TESTS OF PULLEYS.

An extended series of tests was recently made with different kinds of pulleys transmitting power by means of leather belts, on a belt-testing machine in the laboratory of Sibley College, Cornell University. The tests were all made with single-ply oak-tanned leather belts 5 in. wide, 0.224 in. thick and 33 ft. long. The pulleys were all nominally 24 in. diam. with 8-in. faces. A constant belt speed of 2,200 ft. per min., or 348 r.p.m. of the driving pulley, was maintained throughout. Cast-iron, wood, and paper pulleys were used, including some with cork projections. The exhaustive character of the tests is shown by the fact that for cast-iron pulley tests alone nearly 9,000 observations of the slip of the pulleys were taken.

The results of these tests were given, in a paper by Prof. W. M. Sawdon, before the National Association of Cotton Manufacturers.

The tests showed that for slips of 1 to 2 per cent., as commonly used in practice, the plain cast-iron pulley had the lowest values of coefficient of friction and the plain paper pulley had the highest. The values of the plain wood pulley lay between these limits. Wood pulleys up to ½ per cent. slip followed very closely the performance of the paper pulleys, after which the slip increased rapidly, and at 1 per cent. the coefficient of friction was only approximately a mean between those of the cast-iron and the paper pulleys. Beyond 3 per cent. slip the coefficient of friction was less than that for cast iron. This condition explained in part a commonly accepted understanding that the wood pulley had a small capacity for carrying an overload. To take care of overload capacities as much as 50 per cent. of the normal load, the wood pulleys must be designed larger in diameter or for use with a wider belt than the normal load would demand.

Pulleys with cork inserts 1¼ in. diameter, set in 1 1/16 in. diameter sockets and spaced 2¼ in. between centres, and of composite construction, were tested. This gave a cork area of from 37 to 39 per cent. of the total pulley face. The usual practice was to make the cork area from 25 to 33⅓ per cent. of the total area. Two separate and complete tests were made on the cork inset pulleys, one for a projection of the corks of approximately 1/32 in. beyond the pulley face and the other for a projecion of approximately 1/64 in. In the case of the cast-iron pulleys, each of the cork-insert curves showed a material increase in the values of the coefficient of friction at lower slips and running up to 3 per cent. For the longer corks the values of the coefficient of friction between 1 and 6 per cent. slip were close to those of the plain wood pulleys. Below 1 per cent. slip the wood pulleys had the higher values. With the shorter corks, considerable advantage was shown over plain cast-iron pulleys as well as plain wood pulleys up to about 4 per cent. slip, after which the coefficients were but little higher than for the plain cast iron. Either of the cork insert cast-iron pulleys, however, showed a large overload capacity at high slips. In the wood pulleys the cork inserts slightly increased the transmitting capacity for very low slips and up to about ⅛ of 1 per cent. Between ½ and 1¾ per cent. slip the plain wood pulleys had the higher values, while beyond 2½ per cent. the cork inserts again showed an advantage. This was particularly interesting in that, though capable ultimately of carrying much greater loads, through the allowable ranges of slip, the cork inserts actually proved detrimental. The tests on the paper pulleys with cork inserts were also interesting in that in each case the use of cork inserts had proven detrimental to the transmitting capacity of the pulleys for practically the entire range of slip. For the longer cork projection this was more marked than for the shorter. Unfortunately, in the paper and in the cork pulley tests, the capacity of the machine did not permit of higher loads being carried to determine the maximum values of the coefficient of friction and corresponding slips.

A NEW BRIDGE IN EGYPT.

In connection with the opening up for navigation purposes of that branch of the River Nile at Cairo, known as the Bahr-el-Aama, and the proposed realignment of the navigable channel of the river, tenders for the construction of an entirely new bridge to replace the existing Pont des Anglais were invited by the Egyptian Public Works Department from all the leading bridge engineering firms of Great Britain, Continental Europe and North America.

Out of six tenders submitted that of the Cleveland Bridge and Engineering Company (Limited), of Darlington, England, has been accepted. The firm undertakes to complete the bridge in 22 months, the price being $300,000. The bridge is required to accommodate road and tramway traffic and there will be footpaths carried upon cantilevers on either side, the width of the bridge between parapets being 19 metres. In addition to two approach spans there will be a rolling lift span giving a clear opening for river traffic of 63 metres. The bridge is of a distinctly artistic design, and will be finished in ashlar, drawn from quarries near Cairo.

OBITUARY.

The death is reported of Mr. H. J. Fairweather, electrical engineer in charge of the power-house of the Canadial General Electric Works, at Peterborough, Ont. Mr. Fairweather was drowned while cleaning away ice in the flume. His original home was New Brunswick, where his wife, a daughter of Mr. R. B. Rogers, C.E., and a two-weeks-old baby are at present.

PERSONAL.

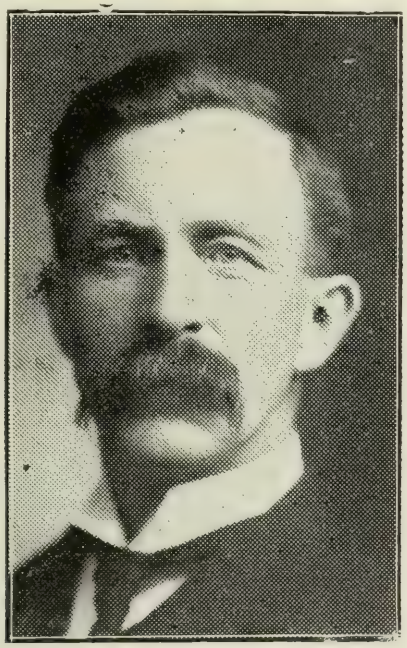
Captain W. C. Hemeon has been appointed harbor master of the Port of Liverpool, province of Nova Scotia.

Mr. E. C. Miller has been appointed Toronto representative of Messrs. T. Pringle & Sons, Coristine Building, Montreal. Mr. Miller will locate his office at 509 Continental Life Building.

Mr. Chas. K. Howard, former travelling freight agent of the Canadian Pacific Railway, with headquarters at Fredericton, N.B., has accepted an appointment with the St. John and Quebec Railway Company.

James Oborne, general superintendent of the C.P.R. at Toronto, has been appointed general superintendent at Vancouver, B.C.

Prof. L. B. Stewart, of Toronto, has been elected president of the Royal Astronomical Society of Canada. Prof. Stewart is professor of Surveying, Faculty of Applied Science, Toronto University. He was one of the first professors



Prof. L. B. Stewart.

appointed on the staff of the old School of Science, which later became the Faculty of Applied Science and Engineering of the University of Toronto. He is one of the few men in Canada who hold the degree of D.T.S. (Dominion Topographic Surveyor.)

Mr. E. Cousins, as announced in last week's issue, has been appointed to the position of engineer to the Commission of Harbors, City or Toronto. Mr. Cousins has been an as-

Mr. E. Cousins.

sistant engineer for Toronto since July, 1910, having had charge of the railway department since his appointment, and of bridges and docks since last February. The plans which he has prepared for the city include the Ashbridge Bay docks, Princess street dock, groynes at Kew and Balmy Beach, sea wall and the underground railways and civic surface lines. He has also had superintendence over the Don industrial tracks, Sunnyside grade separation, Don high level bridge, completion of Wilton avenue bridge, and Weston road viaduct construction.

Mr. Cousins is an honor graduate of the Faculty of Applied Science, University of Toronto.

Mr. W. L. Woodroofe has been appointed to the position of electrician for the city of Vancouver, B.C. Mr. Woodroofe has had considerable experience with the British Columbia Electric Railway.

THE ANNUAL DINNER OF THE FACULTY OF APPLIED SCIENCE, UNIVERSITY OF TORONTO.

The twenty-third annual dinner of the Engineering Society of the Faculty of Applied Science and Engineering of the University of Toronto, was held on January 18th in the Convocation Hall of the University of Toronto, Mr. W. B. McPherson the president of the Engineering Society was in the chair.

A very interesting address on the progress of the work undertaken by the Dominion Conservation Commission was given by Secretary Patton of that body, who came at the request of the chairman, Mr. Clifford Sifton, after the commission closed its annual meeting at Ottawa.

Dr. Ellis responded to the toast of the University, and Mr. W. F. Tye, consulting engineer, and president elect of the Canadian Society of Civil Engineers, responding to that of "The Engineering Profession," gave the students a history of old-time engineering as compared with that of the present, pointing out the difference in the way the profession and the public used to treat graduates of engineering schools and the way they are now treated.

Mr. George Guess, the new professor of metallurgy, was introduced, and spoke briefly. Dean John Galbraith made a short speech on engineering and university topics in general.

Student representatives were present from McGill and Queen's Universities, and among the guests were Mr. W. B. McPherson, K.C., M.P.P.; Mr. P. W. Ellis, of the Toronto Hydro-Electric Commission; Mr. J. W. Tyrrell, the Arctic explorer, of Hamilton; Mr. P. W. Sothman, chief engineer of the Ontario Hydro-Electric Commission; Mr. C. H. Rust, outgoing President of the Canadian Society of Civil Engineers; Dean B. E. Fernow of the University Faculty of Forestry; Engineers J. G. Sing, Willis Chipman, and T. Aird Murray, and Controller Church. The School of Science Orchestra and the science octette gave several selections.

ANNUAL MEETING BUILDERS' EXCHANGE, MONTREAL.

The keynote of the toasts which were proposed at the annual banquet of the Builders' Exchange in Montreal on January 9th, was constructive throughout, covering the building up of the Dominion, of the city, and of the nation. There were present two Cabinet Ministers, the Postmaster-General, Hon. Louis B. Pelletier, and Hon. Dr. Sproule, as well as ex-Postmaster-General Rodolphe Lemieux, the first named urging better transport facilities for the wheat harvest and the formation of a Canadian Lloyds route, while Dr. Sproule deprecated the letting loose of strikes by unions just at the inopportune time, and also took a fling at the trusts.

There were about 180 guests present at the banquet in the Windsor Hotel, under the presidency of Mr. James J.

Ballantyne. Mr. Ballantyne spoke briefly on behalf of the exchange, and made allusion to the hardship suffered by builders in regard to stone coming in. He advocated the raising of the duty, and pleaded that some measure of protection should be given the builders against American contractors.

ELECTIONS OF ROYAL ASTRONOMICAL SOCIETY OF CANADA.

Professor L. B. Stewart, of Toronto, was elected president of the Royal Astronomical Society of Canada at the annual meeting of the society. Dr. W. F. King, C.M.G., Ottawa, was elected honorary president; Mr. J. S. Plaskett, B.A., Ottawa, first vice-president; Dr. A. D. Watson, Toronto, second vice-president; Mr. J. R. Collins, Toronto, secretary; Mr. Charles B. Sparling, Toronto, treasurer; Mr. Lachlan Gilchrist, M.A., Toronto, recorder, and Dr. W. M. Wunder, Toronto, librarian. The executive committee was the same as last year, with the exception that G. Parry Jenkins, F.R.A.S., of Hamilton, was elected to a vacancy. It was announced by the representatives from Guelph that Mr. Henry Westerby, the president of the branch, had presented the society with a six-inch telescope, which is the same size as the one in the tower in the Meteorological Observatory in Toronto.

COMING MEETINGS.

THE CANADIAN SOCIETY OF CIVIL ENGINEERS.—Jan. 24, 25, 26, 1912. General meeting, 413 Dorchester St. West, Montreal. Prof. C. H. McLeod, Secretary.

CANADIAN FORESTRY ASSOCIATION.—February 7th and 8th, 1912. Forestry Convention Meetings held in the Railway Committee Room, Parliament Buildings, Ottawa. Secretary, Mr. James Lawler, Canadian Bldg., Ottawa.

CANADIAN LUMBERMEN'S ASSOCIATION.—February 6, 7 and 8, 1912. Annual Meeting to be held at the same time and place as the Canadian Forestry Association.

CANADIAN NATIONAL ASSOCIATION OF BUILDERS. — The Sixth Annual Convention will be held in Toronto, February 20, 1912.

ONTARIO GOOD ROADS ASSOCIATION.—Annual Convention to be held at Toronto, February 26, 27, 28. Secretary, J. E. Farewell, Whitby.

THE CLEVELAND ENGINEERING SOCIETY.—Regular Meeting, Tuesday Evening, February 13, 1912, Chamber of Commerce Bldg., Cleveland, O. Address by Mortimer E. Cooley, Dean, Department of Engineering, University of Michigan; Subject: "Public Utilities and Their Relation to the Public." Secretary, F. W. Ballard.

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, C. H. Rust; Secretary, Professor C. H. McLeod.

QUEBEC BRANCH—
Chairman, P. E. Parent; Secretary, S. S. Oliver. Meetings held twice a month at Room 40, City Hall.

TORONTO BRANCH—
96 King Street West, Toronto. Chairman, T. C. Irving; Acting Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the month at Engineers' Club.

MANITOBA BRANCH—
Secretary E. Brydone Jack. Meets every first and third Fridays of each month, October to April, in University of Manitoba, Winnipeg.

VANCOUVER BRANCH—
Chairman, Geo. H. Webster; Secretary, H. K. Dutcher, 319 Pender Street West, Vancouver. Meets in Engineering Department, University.

OTTAWA BRANCH—
Chairman, S. J. Chapleau, Ottawa; Secretary, H. Victor Brayley, N. T. Ry., Cory Bldg.

MUNICIPAL ASSOCIATIONS.

ONTARIO MUNICIPAL ASSOCIATION.—President, Chas. Hopewell, Mayor, Ottawa; Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

UNION OF ALBERTA MUNICIPALITIES.—President, H. H. Gaetz, Red Deer, Alta.; Secretary-Treasurer, John T. Hall, Medicine Hat, Alta.

THE UNION OF CANADIAN MUNICIPALITIES.—President, W. Sanford Evans, Mayor of Winnipeg; Hon. Secretary-Treasurer, W. D. Lighthall, K.C., Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer, J. W. McCready City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. E. McMahon, Warden, King's Co., Kentville, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secretary, Mr. Heal, Moose Jaw

CANADIAN TECHNICAL SOCIETIES.

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang; Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BUILDERS, CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Charles Kelly, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto.

CANADIAN ELECTRICAL ASSOCIATION.—President, N. W. Ryerson, Niagara Falls; Secretary, T. S. Young, Canadian Electrical News, Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, Thomas Southworth, Toronto; Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President. Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; J. Keillor, Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. Frank D. Adams, McGill University, Montreal; Secretary, H Mortimer-Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, T. A Starkey, M.B., D.P.H., Montreal. Secretary, F. C. Douglas, M.D., D.P.H. 51 Park Avenue, Montreal.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, D. McDonald, Manager, Montreal Street Railway; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto, President, G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July, August.

DOMINION LAND SURVEYORS.—President, Thos. Fawcett, Niagara Falls; Secretary-Treasurer, A. W. Ashton, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, W. B. McPherson; Corresponding Secretary, A. McQueen.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President, Killaly Gamble; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian Members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain, and W. H. Miller, and Messrs. W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary, R. C. Harris, City Hall, Toronto.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C.B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, W. H. Pugsley, Richmond Hill, Ont.; Secretary, J. E. Farewell, Whitby.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, J. Whitson; Secretary, Killaly Gamble, 703 Temple Building, Toronto.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary J. E. Ganier, No. 5. Beaver Hall Square, Montreal.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, F. S. Baker, F.R.I.B.A., Toronto, Ont.; Hon. Secretary, Alcide Chausse, No. 5 Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Dr. A. McGill, Ottawa, President; Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, J. P. McRae; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Wm. Pierce, Calgary; Secretary-Treasurer, John T. Hall, Brandon, Man.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. Rosevear, 115 Phœnix Block, Winnipeg, Man. Second Monday, except June, July and August, at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc. Printed forms for the purpose will be furnished upon application.

TENDERS.

Calgary, Alta.—Plans are being prepared for the building of a new school for South Calgary. The building will be 200 x 140, fireproof, hollow tile and concrete floors. Estimated cost, $150,000.

Fredericton, N.B.—The St. John and Quebec Railway Company contemplate making their first call for tenders for construction work on the St. John Valley Railway about the middle of February.

Galt, Ont.—Tenders will be called for waterworks, 250 k.v.a., 2,200 volts motor, direct connected to centrifugal pump. Specifications prepared by the Hydro-Electric Commission, Toronto.

Hamilton, Ont.—Tenders will be received until February 6th, 1912, for supplying the corporation of the City of Hamilton with the following: Works Supplies—sewer pipe, line, sewer brick, castings, asphalt, creosoted wooden blocks, Portland cement, road oil, gravel, lumber, lead pipe, pig lead, iron pipe, valves, hydrants, and extension boxes. Specifications for above can be obtained at the office of the city engineer, S. H. Kent, city clerk, City Hall, Hamilton.

Hamilton, Ont.—S. H. Kent, city clerk, City Hall, will receive tenders for the various trades in alterations to the City Hall, until January 31st, 1912. Full information obtained at the office of Mills & Hutton, architects, Room 804, Bank of Hamilton Building.

Lajord, Sask.—Tenders will be received until Saturday, February 10th, 1912, for the construction of a two-room two-storey and basement brick school building. Plans and specifications may be obtained from the secretary-treasurer of the Prairie Flower School District No. 989, Mr. A. W. Rogers, Lajord, Sask.

Ottawa, Ont.—Tenders will be received until January 30th, 1912, for the supply of some 210,000 barrels of cement, more or less, required for the construction and maintenance of the various canals of the Dominion, and to be delivered in such quantities at such places and at such times as may be directed. Specifications, etc., can be obtained from the Purchasing Agent of the Department of Railways and Canals, Ottawa. L. K. Jones, Secretary Dept. of Railways and Canals.

Ottawa, Ont.—Tenders will be received by the Dept. of Public Works until February 14th, 1912, for the construction of a wharf at Little Lameque, Gloucester County, N.B. Plans, specifications, etc., can be obtained at the offices of Geoffrey Stead, Esq., Dist. Engineer, Chatham, N.B.; E. T. P. Shewen, Esq., Dist. Engineer, St. John, N.B.; the Postmaster at Lameque, N.B., and at the office of R. C. Desrochers, Secretary Dept. of Public Works, Ottawa.

Ottawa, Ont.—Tenders will be received at the Dept. of the Interior, until noon of the 31st day of January, 1912, for the furnishing of iron posts for use on the survey of Dominion Lands, to be delivered as follows:—At Winnipeg, five thousand small and one hundred and fifty large posts; at Edmonton, one hundred and fifty large posts. Forms of tender and detailed information may be obtained from the Surveyor-General of Dominion Lands, Ottawa. P. G. Keyes, Secretary Dept. of the Interior.

Ottawa, Ont.—Tenders will be received until February 15th, 1912, for the construction of a dam and sluiceways below the outlet of Lake Quinze at the head of Maple Rapids, in the Townships of Guerin and Baby, County of Pontiac, Que. Plans, specifications and forms of tender can be obtained at the offices of J. G. Sing, Esq., Dist. Engineer, Confederation Life Bldg., Toronto; J. L. Michaud, Esq., Dist. Engineer, Merchants Bank Bldg., St. James St., Montreal; on application to the Postmaster at Haileybury, Ont., and at the office of R. C. Desrochers, Secretary Dept. of Public Works, Ottawa, Ont.

Ottawa, Ont.—Tenders will be received until February 7th, 1912, for the erection of a public building at Lloydminster, Sask. Plans, etc., may be obtained at the offices of Mr. J. E. Cyr, Supt. of Public Buildings for Manitoba; Post Office Bldg., Winnipeg, Man.; at the Post Office at Lloydminster, and at the office of R. C. Desrochers, Secretary Dept. of Public Works, Ottawa.

Ottawa, Ont.—Tenders are being invited by the Department of Public Works for the construction of a pier at Upper Salmon River, Albert County, N.B. Received until Wednesday the 14th of February, 1912. Plans, etc., at the offices of E. T. P. Shewen, district engineer, St. John, N.B..; Geoffrey Stead, district engineer, Chatham, N.B.; the Postmaster at Alma, N.B., and at the office of R. C. Desrochers, secretary, Department of Public Works.

Regina, Sask.—Tenders will be received until Feb. 16, 1912, for the several trades required in the erection and completion of a theatre in the town of Swift Current, Sask. Plans, etc., at the office of Messrs. Sharon & Darrach, Architects, Regina.

Saskatoon, Sask.—Tenders will be received by the City Commissioners until February 23rd, 1912, for the construction of the sub-structure for a subway under the Canadian Northern Railway Company's tracks at 23rd Street, in the City of Saskatoon. (See adv. elsewhere in the Can. Eng.)

Toronto, Ont.—Tenders are being called by the chairman of the Board of Control, City Hall, Toronto, until Tuesday, February 20, 1912, for the supply of track intersections and other special work layouts. (See advertisement elsewhere in The Canadian Engineer.)

Toronto, Ont.—The Temiskaming & Northern Ontario Railway Commission will shortly be in a position to call for tenders for the construction of the extension into the Elk Lake District.

Toronto, Ont.—Tenders will be received, addressed to the Chairman of the Joint Building Committee of the Y.M.C.A. till noon, Monday, February 5th, for the various trades required in the erection of the Central Building, Nos. 30-40 College Street and 35-47 Grenville Street. Burke, Horwood & White, Architects, 25 Toronto St.

Toronto, Ont.—Tenders will be received until Jan. 31st, 1912, for the construction of concrete abutments and a steel bridge, 100 feet clear span, and also for a reinforced concrete truss bridge, 50 feet clear span, over the Burnt River in the Village of Haliburton, Municipality of Dysart. Frank Barber, Civil Engineer. (Adv. in the Can. Eng.)

Toronto, Ont.—Tenders will be received by the Chairman of the Board of Control, City Hall, until noon, Tuesday, Jan. 30th, 1912, for the construction of sewers. (See adv. elsewhere in the Can. Eng.)

Victoria, B.C.—Tenders will be received until the 31st day of January, 1912, for the erection and completion of a gymnasium for the Provincial Normal School, Vancouver, B.C. Plans, specifications, etc., at the office of the Timber Inspector, Vancouver, B.C.; the Government Agent, New Westminster, B.C.; and the Dept. of Public Works, Parliament Buildings, Victoria.

Winnipeg, Man.—The date for delivery of preliminary plans in connection with competitive drawings for the new Parliament Buildings, to be erected in the city of Winnipeg, is extended to March 31st, 1912. Colin H. Campbell, Minister of Public Works. (Adv. in the Can. Eng.)

Winnipeg, Man.—Tenders will be received until February 16th, 1912, for the supply of steel casement sash, linen chute doors and elevator doors, for the King George Isolation Hospital. Plans and specifications may be obtained at the offices of Mr. H. B. Rugh, Architect, 928 Union Bank Bldg. M. Peterson, Secretary Board of Control Office, Winnipeg.

Winnipeg, Man.—Tenders for the supply and installation of a five million gallon horizontal turbine pump driven by an induction motor, direct-connected, will be received until March 1st, 1912. M. Peterson, secretary, Board of Control Office, Winnipeg. (See advertisement elsewhere in The Canadian Engineer.)

Winnipeg, Man.—The Winnipeg Public School Board are open to receive tenders until February 8, 1912, for two motor generator sets and two rotary transformers and generators required in connection with the Kelvin and St. John's Technical High Schools. Specifications, etc., at the office of J. B. Mitchell, commissioner of supplies, School Board Office. R. H. Smith, secretary-treasurer, W.P.S.B.

CONTRACTS AWARDED.

Calgary, Alta.—Messrs. Gorman, Clancy & Grindley, of this city, have closed contracts with the city of Moose Jaw for the supply of upwards of 20 miles of 18½-inch steel pipe for the new gravity water system, to be installed by that city very shortly. The same firm also have a contract with the city of Lethbridge for the supply of 14 miles of rails, together with specials and poles for the Lethbridge Street Railway.

Hamilton, Ont.—The Hamilton Bridge Company has secured the contract for the erection of the new buildings for the Steel Company of Canada. Total cost, $140,000.

Lethbridge, Alta.—The contract for street car equipment has been awarded to United States Steel Products Co., 706 McArthur Bldg., Winnipeg. City Engineer, A. C. D. Blanchard.

Montreal, Que.—The contract for offices and stores on Notre Dame and St. Sulpice Streets, has been awarded to Mr. C. E. Deakin, 11 St. Sacrament Street. Cost, $147,000.

Toronto, Ont.—The Electrical Development Company have awarded the contract for the completion of the power house at Niagara Falls, to Messrs. Page & Co., Toronto. Exclusive of equipment, the power house cost over $500,000, and the new addition will cost between $200,000 and $300,000.

Victoria, B.C.—The contract for the completion of the warehouses and other buildings on the new provincial wharf at Prince Rupert, has been awarded by the provincial minister of works to the Westholme Lumber Company, of this city, the successful tender for the work being at a price of $12,550.

Westmount, Que.—Messrs. Mussens, Limited, Montreal, have the contract for the supply of one steam road roller, at a cost of $3,110. Other tenderers were: Messrs. Brennan & Cairnie, Westmount, $2,900; Messrs. F. Hankin & Co., Montreal, $2,600; Messrs. Chambers & Simpson, Toronto, $2,930. Arch. Currie, City Surveyor.

RAILWAYS—STEAM AND ELECTRIC.

Montreal, P.Q.—The estimates of the Canadian Pacific for 1912 are placed at $20,000,000.

Ottawa, Ont.—During the recent investigation into the telegraph department of the Canadian Pacific Railway lines, it was brought out that the total cost was $6,696,421.40, of which $3,897,238 was for line equipment. This was spread over 12,108 miles of poles, making the average cost $321.87 per mile.

Ottawa, Ont.—It is reported that the Grand Trunk Pacific Railway will seek legislation at the present session of parliament empowering the company to issue additional debenture stock perpetual or terminal, up to a total of $25,000,000. The company needs an additional $15,000,000 to complete its railway, to purchase rolling stock and construct branch lines, etc. Mr. Hays preferred to get the money by way of a government loan, as they got $10,000,000 three years ago, but the new government being found to be less indulgent than the old, the company finds a further issue of debenture stock necessary.

Ottawa, Ont.—The Dominion Railway Commission are preparing a measure to eliminate several level crossings or install certain safety devices.

Ottawa, Ont.—It is reported that a deputation representing an English syndicate has asked for consideration of the charter of the Hudson Bay Pacific Railway Company. This charter was granted in 1906 for the building of a road from Prince Albert to Churchill, but no work was done; the charter, it is understood, has now fallen into the hands of English capitalists, who are asking for the guarantee of their bonds for the carrying out of the project.

Port Arthur, Ont.—The council will apply for legislation to extend the street car system to districts outside the city boundaries.

Toronto, Ont.—Toronto is to be the head office of the Mexican Interurban Electric Traction Company, Ltd., which has been incorporated with a capital stock of $5,000,000. A number of Toronto men are associated with Dr. Pearson, of New York, in the enterprise, among whom are Mr. Z. K. Lash, K.C., vice-president of the Mexico Tramways Company.

Vancouver, B.C.—Property owners are to appeal the offer of the Great Northern Railway for their lots on False Creek. The property owners were given $1 each for their property. The owners first sought a total of $57,000 damages, or an average of $3,000 per lot. The award of the arbitrators of $1 apiece is declared to be far from equitable.

LIGHT, HEAT AND POWER.

Brantford, Ont.—The committee appointed to investigate the possibility of a reduction in the cost of electrical energy, have decided to extend an invitation to the hydro-electric engineers for a report. The contract with the Ontario Power Company does not expire for 27 years yet. A rough estimate from the hydro-electric states that a transforming station to supply 1,500 horsepower, could be erected at a cost of $70,163.

Galt, Ont.—Galt will soon be calling for tenders for a cynchronous motor 250 K.V.A. 2,200 volts, 750 R.P.M., to be used on the waterworks. J. H. Radford, Chairman Waterworks Commission.

Long Sault Rapids, St. Lawrence River.—It is reported that Mr. W. J. Westley, of Morrisburg, has gone to Washington in an effort to overcome certain difficulties in connection with this development.

Niagara Falls, Ont.—A representation from Buffalo, Niagara Falls, N.Y., and Detroit have urged the house of foreign affairs at Washington, D.C., to change the limit of diversion of water on the American side from the present, 15,600 cubic per minute, to the maximum of 20,000 feet as

Charles Street, Stratford, Ontario, showing "Tarvia Modern Pavement."

Stratford's Experience with Tarvia

STRATFORD, Ontario, did some thorough and successful work with Tarvia X in 1910 and the accompanying photograph shows a section of Charles Street in that city built by the Tarvia Modern Pavement Method.

Tarvia X was used as a binder throughout the road on a Telford base. Although the job was done by the somewhat primitive barrel-and-kettle method, the total cost was only $1.32 per yard.

The Tarvia, filling the voids of the stone, acts as a plastic matrix, keeping the stone in position, preventing all internal movement, resisting water and frost, protecting the road against automobile traffic and preventing the formation of dust.

After its first year of use, the street is in excellent condition and is giving perfect satisfaction. It has been visited by various engineers, all of whom agree as to the success of the work.

This is only one of thousands of instances of successful Tarvia construction.

We will be glad to send to any inquirer a booklet showing many other cases.

The Paterson Manufacturing Co., Limited
Montreal Toronto Winnipeg Vancouver

The Carritte-Paterson Manufacturing Co., Limited
St. John, N.B. Halifax, N.S.

authorized by the treaty. They also seek the removal of the present limitation of 160,000 horse-power, that may be imported from Canada.

North Toronto, Ont.—The Water, Fire and Light Committee have recommended that the town council install a motor generator and storage battery system for the fire alarm system. This is to cost $2,000. Mr. E. A. James, Engineer.

Port Stanley, Ont.—It is expected that the hydro-electric line into Port Stanley will be completed in a few days.

Quebec, P.Q.—A new power company, capitalized at $1,000,000, has been formed in Quebec, with Hon. L. P. Pelletier as president. It will be known as Stadacona Light, Heat and Power Company.

Toronto, Ont.—A legal decision of interest to engineers and power house managers, was handed down by Mr. Justice Riddell and two other judges. Their decision allows the Canadian Niagara Power Company to pay for excess power, besides the yearly rental of $15,000, on an average basis, instead of on the individual excess, or "peak load" basis, without regard to times when the power used might be under the limit.

SEWAGE AND WATER.

Calgary, Alta.—The city engineer has recommended that the reservoir be lined along the bottom and sides.

North Toronto, Ont.—The Water, Fire and Light Committee have recommended to the council the sinking of a well to cost $1,500, also that weeping tiles be placed, in order to increase water supply. Mr. E. A. James, engineer.

Ottawa, Ont.—The new intake pipe will be coupled up in from three to four weeks, according to the city engineer. There is about 120 feet to be laid as yet.

Ottawa, Ont.—The engineering firm of Siemen Brothers, London, England, are sending a representative to Ottawa to prepare a report on the water supply question.

Port Arthur, Ont.—The question of securing a municipal water supply from Loch Lomond is again before the council.

Richmond, B.C.—This municipality is preparing a by-law to borrow the sum of $50,000 for the construction of waterworks.

Regina, Sask.—The municipal council intend to make a test within the next few days to ascertain just what water pressure can be maintained and to find out if the supply of water is sufficient for the requirements of the city.

Saskatoon, Sask.—A private corporation which enjoys the privilege of supplying the outlying districts of Saskatoon with water have raised their price to 25c. per barrel. The council are investigating for a reason.

Victoria, B.C.—The city council on the recommendation of the water commissioner decided to purchase 10,000 feet of ten-inch pipe, 10,000 feet of eight-inch pipe, 50,000 feet of six-inch pipe, and 50,000 feet of four-inch pipe at a cost of $55,000. In addition there will be purchased 1,220 water meters of the Trident type at a cost of $17,670. Angus Smith, city engineer.

Weston, Ont.—The council has decided to go ahead with installation of sewage disposal plant. T. Aird Murray of Toronto has been called in as consulting engineer.

BUILDING.

Brantford, Ont.—The Dominion Government have purchased a site on Dalhousie Street on which to erect a $200,000 post office.

Calgary, Alta.—A report states that the Swift Packing Plant of Chicago will erect a branch in Calgary.

Calgary, Alta.—The city engineer, Mr. J. F. Childs, has drawn up an estimate of the cost of providing the city with an asphalt plant, which would be in the neighborhood of $20,000.

Calgary, Alta.—The Canada Malting Company will begin construction work at an early date. This plant will have a capacity of 750,000 to 800,000 bushels per year. They will erect a large elevator, which will have a capacity of 400,000 bushels. The estimated cost is $250,000.

Coquitlam, B.C.—Messrs. Brown & McKay, an eastern firm, are reported to have arranged the purchase of a site for the construction of a steel works to cost $100,000. They have bought a site for a woodworking plant.

Fort William, Ont.—Certain technicalities in connection with the granting of warehouse sites have been overcome. Some of the concerns contemplating building operations in 1912-13 are: The Cameron Heap Company, Fort William; The McLaughlin Biscuit Mfgs., Fort William; The Fife Hardware Company, Fort William; The Fitzsimmons Fruit Company, Fort William; Matthews Pork Packing Company, Fort William; Tees and Peiss of Winnipeg.

Galt, Ont.—A new lighting system is to be installed in the Baptist Church. Mr. S. Misner is financial secretary.

Montreal, P.Q.—The British-Canadian Canners, Ltd., have secured sites for five factories and plan to erect factories this year. The sites are located at Merlin, Highgate, Port Robinson, Bowmanville and Cobourg. Contracts for buildings and machinery, it is reported, will be called for at an early date. The directors of the British-Canadian Canners, Limited, comprise Sir Henry N. Bate, of Ottawa, and J. P. Black, H. A. Lovett, K.C., and R. Brutinel, of Montreal.

Moose Jaw, Sask.—The Jensen Tanneries, of North Dakota, U.S.A., are negotiating with the municipal council for a site on which to erect a $15,000 plant.

Nanaimo, B.C.—The $50,000 School Loan By-law to sanction the borrowing of a sum of money not exceeding $50,000 for the erection of a new school was carried.

North Vancouver, B.C.—The Vancouver Safe Works, Ltd., are considering establishing a plant on the North Shore. The company contemplate taking out a 10 to 20-year lease on two acres of land for the erection of a plant and equipment to cost approximately $50,000, which would give employment to about fifty men.

Oshawa, Ont.—The government have decided to construct an armory, providing the town council supply a suitable site.

Port Arthur, Ont.—The congregation of St. Paul's Presbyterian Church have decided to erect a building to cost $40,000 or $50,000. A committee consisting of L. Walsh, M. Hood, M. W. Bridgman, A. M. Long, F. Urry and L. J. McCutcheon have been appointed to undertake the preliminary work of getting out plans, etc.

Port Arthur, Ont.—Acting for Mackenzie & Mann, and a British syndicate, J. M. Fraser, of the Atikokan Iron Co., submitted to the city an application for the establishment of a $5,000,000 steel plant. The city will give a site of 400 acres at Bare Point and a fixed assessment for twenty years of $50,000 except for school and local improvements.

Port Arthur, Ont.—Mr. D. K. Campbell will erect a 4-story hotel on Arthur St. at a cost of $50,000.

Regina, Alta.—The Rock City Tobacco Company of Quebec, P.Q., have decided to construct a new warehouse in this city, providing a suitable site may be secured. Mayor Drouin of Quebec is president of this company.

St. Catharines, Ont.—The Dominion Government have increased the estimates for this locality by $6,000 for repairs to a bridge at Lock 4, old canal. The estimates for the Welland Canal in addition to the above are: $3,000 for a bridge over the feeder canal, $10,000 for heavy repairs, $8,000 for installing Gowan Safety devices, and $15,000 for the repairing of foundations of locks on the old canal.

Toronto, Ont.—Mr. P. J. Mulqueen, proprietor of the Tremont House, has obtained a permit to erect a hotel structure to cost $80,000. Work is to start about April 1st, 1912.

Toronto, Ont.—The estimates for the property and street cleaning department include $85,000 for firehalls at Wright and Roncesvalles, at Greenwood Avenue, and at St. Clair and Hendrick Streets; $30,000 for a bath house on a site to be acquired from the Harbor Commission, and $26,000 for lavatories. The increase in maintenance over last year is $32,000.

Vancouver, B.C.—There is considerable likelihood of a new city hall being erected. The cost of this is to be $750,000.

MODERN ELEVATORS

FOR FREIGHT OR PASSENGERS

PLUNGER. —Our plunger elevators embody patented features such as a new main valve which prevents bounding when the car stops, and a new control valve which prevents any accidental movement of the car in the opposite direction when passengers are entering or leaving.

ELECTRIC. —Our electric elevators have patented improvements embodying the good features of the drum and traction type and eliminating their bad ones, and giving greater security and economy of operation. These elevators are worthy of the attention of all interested in office and factory building.

MANUFACTURED BY

PACIFIC COAST PIPE CO. LIMITED

Factory: 1551 Granville Street, VANCOUVER, B.C.

P.O. Box 563. Full Particulars and Estimates Furnished.

The aldermen suggest that competitive plans be sought from architects. The intention is to construct a permanent city hall of architectural beauty, and so laid out that wings could be added to it if necessary later on, as the site is ample for city hall needs for many years.

Victoria, B.C.—It is reported that the estimates of Hon. Thomas Taylor, provincial minister of public works, contain an item of $7,000,000 for new roads and public bulidings throughout British Columbia.

ROADS AND PAVEMENTS.

Ottawa, Ont.—Premier Borden is to receive a deputation from the Ontario Motor League, who will urge on the Federal Government the necessity of maintaining good roads in the Province of Ontario and of making grants towards the same.

CURRENT NEWS.

Esquimalt, B.C.—Twelve carloads of steel plates and tank material have arrived for use in the alterations being made to the G.T.P. liner Prince George. The steamer is being equipped to burn fuel oil at the British Columbia Marine Railway Company's yards. It was necessary to construct special tanks in the steamers to contain the supply of oil.

Latchford, Ont.—An acetylene explosion occurred in the rear of the King Edward Hotel. Considerable damage to property resulted.

Ottawa, Ont.—The Dominion Government have decided to restore the bounties on pig iron.

Ottawa, Ont.—A deputation representing the iron and steel industry waited on the government in an effort to obtain from the new government the restoration of the iron and steel bounties and further encouragement for the iron industry.

Ottawa, Ont.—The statement of the municipal treasurer shows a deficit of $78,085. The treasurer's statement is as follows:—

Deficit in city general account, excluding $12,500 for extra land for Lady Grey Hospital, for which debentures are to be issued		$68,163.72
Deficit, interest and sinking fund account		1,705.45
Deficit, street watering		5,071.11
Total deficit		$74,940.28
Less surplus in hospital account	$ 3,882.70	
Net deficit, exclusive of waterworks	$71,057.58	
Waterworks deficit	7,028.00	
Total net deficit		$78,085.58

Province of British Columbia.—The penalties imposed by the timber branch of the Department of Lands for the year 1912 amounted to $13,199. The total timber branch revenue for the province for 1911 amounted to $2,297,452.25.

Province of New Brunswick.—A deputation from New Brunswick are at Ottawa seeking to have an experimental farm established in that province.

Province of Alberta.—The use of a common drinking cup in this province is now against the law.

Province of Manitoba.—At the next session of the legislature there will be inaugurated a "Public Service Commission" for the province. Under this commission will be placed all the public services of the province, including steam and electric railways, gas and electric lighting, telegraphs, telephones, grain elevators and any other public utility.

St. Boniface Man.—A plan to reclaim certain lands now occupied by the River Seine is being prepared for discussion by the municipal council. The plans show a cutting off of the Seine south of the city boundary, and a short cut to the Red River about opposite River Park. An alternate plan shows a cutting of the stream at the St. Boniface Road, which is the southern boundary of the city. Here it is proposed to run the water through a flume in the centre of the road to a point in the Red River shore opposite Bartlett Avenue, Fort Rouge. The ground thus saved is desirable for railway purposes, as yards, and the filling in of the creek would obviate the necessity of bridges. All the railways will be able to use the territory, and new tracks laid east from Winnipeg will be opposed by no such difficulties as are now to be met. The lands are valued at approximately $3,000 per acre.

Toronto, Ont.—The Works Committee have recommended the municipal council to discontinue its policy of insuring laborers against accident, as premiums have amounted to $7,191.73 per annum, and accidents have been fortunately few.

Vancouver, B.C.—Amongst the suggestions made by Mr. Lea, the engineer preparing the plans for the sewage system, was that the city should provide him with an assistant resident engineer to secure data regarding surfaces, make the further investigations as to areas, and report to him. The commission passed a resolution authorizing the chairman to consult with Mr. Lea as to the selection of an engineer.

Winnipeg, Man.—It is the intention of the municipal authorities to construct a submarine telephone cable across the Red River.

Winnipeg, Man.—The faculty of the University of Manitoba has arranged a series of lectures to be given during the month of February. The syllabus is as follows: "The Pitch and Quality of Musical Sound," "Experiments on Flame," "The Mineral Resources of Manitoba," "Water Purification."

Winnipeg, Man.—The Minister of Public Works announces that the time for receiving competitive drawings for the new parliament buildings has been extended to March 1st, 1912.

BUSINESS.

Dauphin, Man.—Fire did considerable damage to the Canadian Northern Railway station at this point. The telegraph office was destroyed.

Kenora, Ont.—Fire destroyed the fire hall, police station and a business block. The damage is placed at $50,000.

Kingston, Ont.—The municipal council are about to consider the installation of a heating system for the city hall, to replace the box stove method now in use.

Medicine Hat, Alta.—There is a probability of the Ogilvie flour mill coming to this city, and negotiations are in course of progress between the municipality and a representative of the company. The head office of this company is in Montreal, P.Q.

Montreal, P.Q.—$125,000 damage was caused by fire to the building and contents of the Richelieu and Riendeau hotels, and the Hobb Glass factory.

Port Stanley, Ont.—It is stated that the Dominion Government will erect a fish hatchery at this point in the near future.

Port Arthur, Ont.—The fire, water and light committee have been instructed to purchase a new fire engine of not less than 600 gallons capacity.

St. Mary's, Ont.—$10,000 damage was caused by fire to the plant of the St. Mary's Wood Specialty Company. The sawmill and part of the main building were destroyed.

Shoal Lake, Man.—A loss of $25,000 was caused to the business district of Shoal Lake.

St. Boniface, Man.—The plant of the Winnipeg Steel Granary and Culvert Company, in the outskirts of St. Boniface, was totally destroyed by fire with a loss of $15,000.

Sudbury, Ont.—The Canadian Copper Company's hospital was destroyed by fire. The loss is estimated at $50,000.

Toronto, Ont.—Fire damaged the R. D. Fairbairn & Company and the Allen Manufacturing Company's building to the extent of $250,000.

Toronto, Ont.—The Dominion Foundry at 400 East Front Street, owned by Messrs. Blatchford & Trelour, was damaged to the extent of $10,000 by fire.

Winnipeg, Man.—$100,000 damage was caused by fire to the plant and building of the Winnipeg Cold Storage Co.

Winnipeg, Man.—Damage of $20,000 was caused by fire to the Lightfoot furniture storage warehouse.

Heat and Oil-Resisting Steam Hose

You don't buy hose every day. When you *do* buy, it's up to you to remember that the *best* you can buy *today* is the *cheapest* you can use tomorrow---and demand

GOODYEAR

Steam and Hot Water Hose

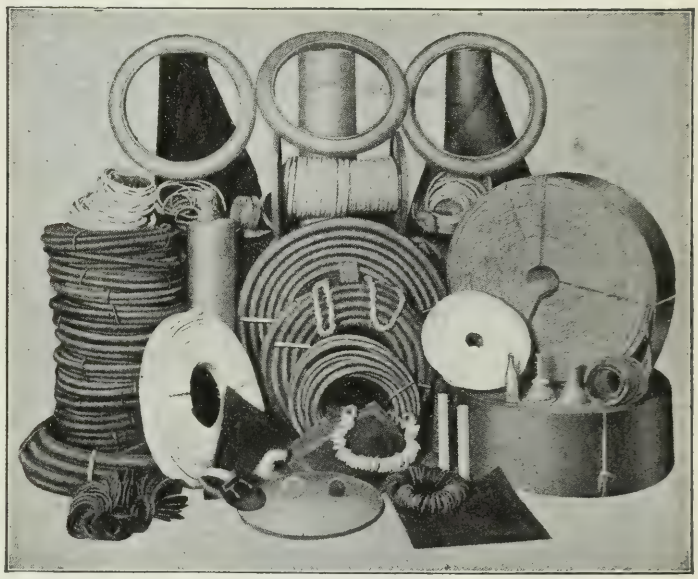
Dependable Hose for Boiler Rooms

This hose is *specially treated* to yield the maximum resistance to steam and *oil*—agencies that play havoc with other hose, *shortening its usefulness and doubling its cost.* The toughest, strongest, least-affected-by-heat hose in existence — and the most economical.

In addition to Goodyear Steam and Hot Water Hose, we also make highest grade

Fire Hose
Air Hose
Suction Hose

as well as special hose for



A Few of the Lines We Manufacture

Oil, Gasoline, Vinegar, Fire Extinguishers, Brewers and Divers

If *ultimate saving* is worth your while, buy *Goodyear* Hose. In every foot you get the same high quality material, skillful workmanship and years of experience that have built such enduring service into the products of the Goodyear Tire & Rubber Company, Akron, Ohio, U.S.A. Tell us what kind of hose you are interested in. Let us quote you a *saving* price—and ship you *saving* goods. 8

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA.

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from The Canadian Engineer for small fee.

15748—January 4—Authorizing C.N.O. Ry. to cross public road, Twp. of Nelson, County of Halton, Ontario.

15749—January 3—Authorizing City of Winnipeg to extend Ellice Avenue across C.P.R. Pembina Branch.

15750—January 3—Approving location of South Ontario Pacific Ry. station at Progresston, mileage 5.32, Twp. of East Flamboro, Ontario.

15751—December 14—Directing that G.T.R. employ watchman from May 1 to October 1 of each year at crossing just east of Grimsby Beach, Ontario; 15 per cent. by Twp. of Grimsby, remainder by G.T.R.

15752—January 3—Extending until June 1, 1912, time for making changes by G.T.R. to water standpipes at Alexandria, Ont.

15753—January 11—Approving plans for spur track to property of W. H. Haight, Piper's Siding, B.C., G.N.R.

15754—January 8—General Order re Freight Rates Western Canada.

15755—January 8—Authorizing C.P.R. to construct spur for Bardsley and Peterson in N.E. ¼ Sec. 4, Twp. 2, R. 7, W. 2 M.

15756—January 8—Authorizing G.T.R. to construct spur for Lautz Co., village of Bridgeburg, Ontario.

15757—December 28—Directing Atlantic, Quebec & Western Ry. to provide farm crossing for Arsene Lelievre, Little River East, joint crossing with A. Shannon. See No. 15456, November 22, 1911.

15758—January 8—Authorizing C.N.O. Ry. to construct its line from present tracks of Central Ontario Ry. at Stanley Street, Trenton, Ont., to railway bridge across Trent River.

15759—January 8—Naming express collection and delivery limits for City of Strathcona, Alta.

15760—January 4—Authorizing C.P.R. to divert road allowance in Twp. of Mara, County Ontario, mileage 41.56 from Victoria Harbor.

15761-62—January 4—Authorizing C.N.O. Ry. to take of Geo. W. Burgess and John Penny, in City of Belleville, Ont.

15763—January 8—Authorizing G.T.P.B.L. Co. to cross with its Melville-Regina Line public road at mile post 42, Lebret, Sask.

15764—January 9—Directing that crossing over Yonge Street, Simcoe, Ont., G.T.R., that when watchman is not on duty that crossing be protected by flagman for all switching movements.

15765—January 5—Directing C.N.R. to complete by February 15, 1912, under penalty of $10 per day to erect wind breaks, etc., just east of Melfort, Sask. Complaint L. I. District, 428 South Melfort, Sask.

15766—December 13—Approving plans for new station by G.T.R. at Stoney Point, Ont., station at new location.

15767—January 3—Authorizing C.P.R. to cross with its Swift Current to Brooks Branch twenty-three highways in Saskatchewan.

15768—January 11—Authorizing C.P.R. to construct sidings into Union Stock Yards, at Toronto, Ont.

15769—January 9—Authorizing C.N.O. Ry. to open for carriage of traffic its line from Harrowsmith to Sydenham, mileage 160.50 to 163.50 from Don Junction, Ont.

15770—January 11—Authorizing Government of Saskatchewan to divert highway and cross C.P.R. at Foam Lake, Sask.

15771—January 9—Authorizing G.T.P.B.L. Co. to cross with its Melville-Regina Branch highways and to divert same at mileage 85.9 and 58.9, Saskatchewan.

15772—January 9—Authorizing T., H. & B. Ry. to discontinue operation of its interlocking appliances at crossing of Hamilton Street Ry. Co. at Barton Street East, Hamilton, until May 1, 1912, crossing to be protected by flag during passage of trains.

15773—January 11—Authorizing C.P.R. to operate spur into premises of Lowe Bros., Sorauren Avenue, Parkdale, Toronto, Ont.

15774-75—January 10—Extending until March 31 and May 31, 1912, time for completion by C.P.R. of subways at point in Sec. 34, Twp. 24, R. 2, West 5, M. and at Jane Street, West Toronto, Ont.

15776—January 12—Approving Lachine, Jacques-Cartier & Maisonneuve Ry. Co. location 400 feet west of C.P.R. crossing at Iberville Street to terminal at St. Catharine Street, Montreal, through lands of C.P.R., subject to agreement between the two companies.

15777—January 8—Directing that before June 15, 1912, the C.P.R. provide an interchange track with G.T.R. in town of Goderich, Ont.

15778—January 9—Naming express collection and delivery limits for town of Brigthon, Ont.

15779—January 10—Directing Canadian Express Co. to file tariff before January 25, 1912, abolishing extra charge between Pictou, N.S., and Charlottetown, P.E.I., except where it shall be necessary (owing to weather conditions) for traffic to be carried to Georgetown, P.E.I.

15780—January 4—Directing C.P.R. to not later than February 10, 1912, institute by providing two passenger trains a day each way between Ottawa and Prescott. Complaint Hon. J. D. Reid.

15781—January 8—Authorizing C.N.R. to cross with its Vegreville-Calgary Branch over tracks of C.P.R. McLeod Branch in S.W. ¼ of Sec. 11, Twp. 24, R. 1, West 5 M., Alta., by means of overhead bridge.

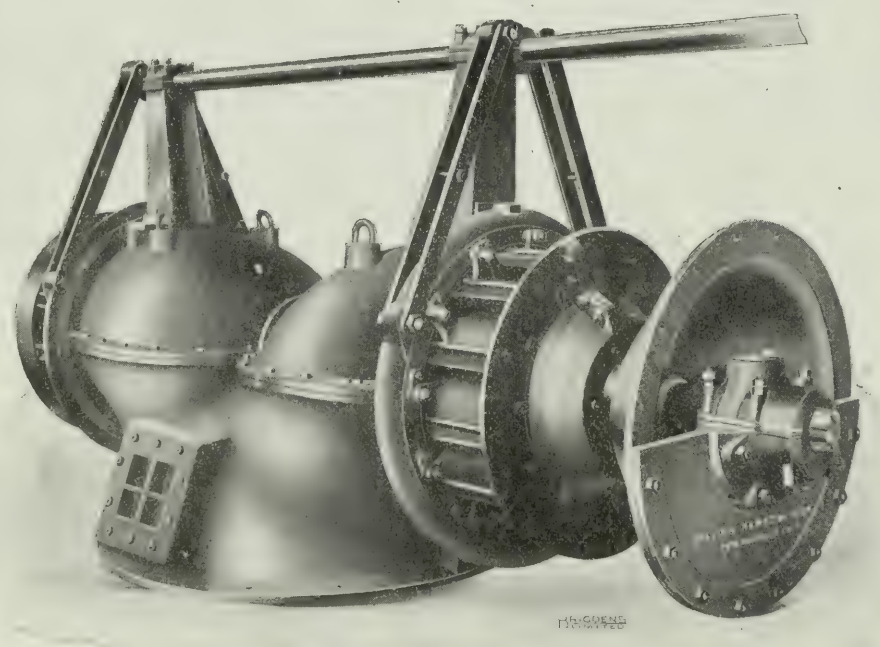
15782—January 9—Authorizing N.Y.C. & H.R.R. to reconstruct interlocking plant at crossing of G.T.R. at Cecile Jct.

15783-84—January 8—Granting certificate correcting omissions and errors in plan of G.T.P.B.L. Co. location, Regina-Boundary Branch.

15785—January 10—Authorizing C.P.R. to construct its Wilkie to Anglia Branch across twelve highways, mileage 0 to 19.37, Saskatchewan.

15786—January 10—Authorizing G.T.R. to construct siding into premises of International Varnish Co., Ltd., and Pinchin, Johnson & Co. (Canada), Ltd., Toronto, Ont.

15787—January 10—Authorizing T., H. & B. Ry. to construct five spurs in City of Brantford, into lands of Verity Plow Co., Ltd., through lands of the New England Co.



Water Wheel Installations

The Canadian Engineer

An Engineering Weekly

STRAIN MEASUREMENTS OF STEAM BOILERS.

Two 72-inch boilers which had been in active operation for 27 years were contributed for investigative purposes by the late Nicholas Sheldon, treasurer of the Kendall Manufacturing Company, of Providence, R.I. They were made by the Whittier Machine Company, of Boston, Mass., out of "Benzon" steel, were put into service in March, 1881, and had never required repair or renewal in any part. They were made in five courses, two sheets to a course, and had the following general dimensions:

Diameter	72 in.
Length, over dry sheet	16 ft.
Thickness of shell	⅜ in.
Thickness of heads	½ in.
Number of tubes	140
Diameter of tubes	3 in.
Length of tubes	15 ft.
Diameter of dome	2 ft. 6 in.

Longitudinal seams, double-riveted lap joints, ¾-inch rivets, 2-inch pitch, punched holes, rows 2⅜ inches apart, rivets staggered.

Girth seam, ¾-inch rivets, 2⅛-inch pitch.

Heads stayed, each, with 14 braces.

Cast-iron manhole frames and safety-valve nozzle.

Supported by lugs, three on a side.

The feed-water came from the Pawtucket river.

The utmost advantage of this opportunity was secured by placing in charge of the tests James E. Howard, qualified by long years of service as the head of the government test-

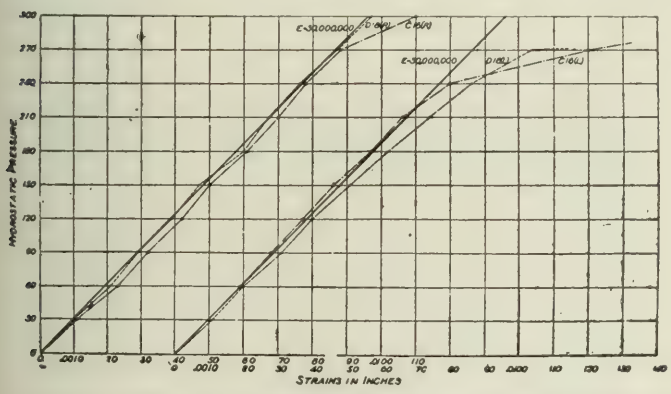

Fig. 1.—Curves of Tangential Extension, Solid Sheets, at Middle of Length of Courses.

ing plant, at the Watertown arsenal and now engineer-physicist of the Bureau of Standards, at Washington. He was advised and assisted by Francis B. Allen, vice-president of the Hartford Steam Boiler Inspection and Insurance Company. The tests were made at the W. H. Hicks Boiler Works, Providence, and form the subject of a paper to be presented at the December meeting of the American Society of Mechanical Engineers, from which the following information is derived:

The tests were made by subjecting the boilers to hydrostatic pressure and measuring the deformation at various points. For this purpose holes about 0.05 inch in diameter and 0.10 inch deep were drilled 10 inches apart in various portions of the shell, and reamed with a reamer having an angle of 65 degrees. A 10-inch strain gauge having conical points with an angle of 55 degrees, adjustable with a micrometer screw, was used to measure the distances between these holes as they varied under stress. The difference in

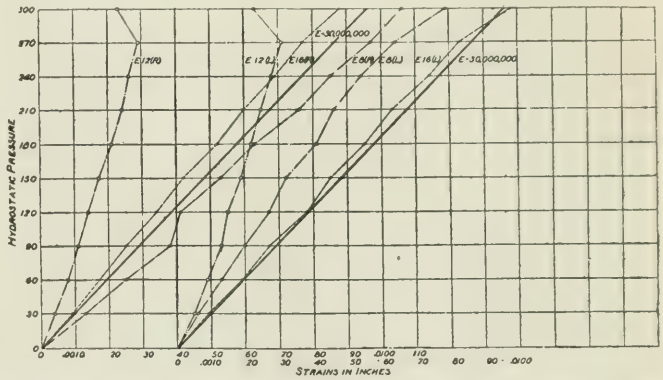

Fig. 2.—Curves of Tangential Extension, Solid Sheets, End Course Near Rear Head, Girth Seam and Middle of Length of Course.

angles made the gauge bear near the surface of the sheet and it is believed that the readings are reliable to $\frac{1}{10,000}$ inch. The stress which would produce an elongation of this amount in a distance of 10 inches is 300 pounds per square inch, assuming a modulus of elasticity of 30,000,000 pounds; that is, supposing that the stress per square inch divided by the stretch per inch of length would equal 30,000,000.

The boilers tested were of a very simple type, yet in very few instances were strains developed corresponding to those which would be indicated by the usual calculation for strains in a cylindrical shell subjected to internal pressure.

In Fig. 1 are laid off in a horizontal direction the amounts of stretch which would be produced by various pressures per square inch in a plain cylinder and with a modulus of elasticity of 30,000,000, each at a height corresponding to the pressure required to produce it. A pressure of 60 pounds per square inch in the interior of a cylinder of this diameter and thickness of shell would, for instance, produce a stretch of nearly 0.0020 inch in a length of 10 inches; and a pressure of 300 pounds a stretch of about 0.0095 inch. The points so determined would lie in the heavy straight line of the diagram marked E = 30,000,000. The distortions actually found were set off in the same way and connected by the lighter lines. They show the extensions of the third and fourth sheets of the boiler, counting from the front on the right and left sides of the boiler respectively, taken at the middle of the lengths of the courses. The courses are lettered A, B, C, D, E; C—16 R. on the diagram means gauged length 16 on sheet C, right-hand side. These follow

the heavy reference line for the ideal condition quite closely upon one side of the boiler, but the leaning to the right of the plotted lines of the other diagram indicates more than a normal stretch.

The strains produced at the various places measured are plotted in this way and the diagrams accompany the paper. E-8 was taken near the girth seam between this and the next sheet and E-16 in the centre of the rear sheet close to, but not spanning, the longitudinal joint. Diagrams of the boiler are given in the paper showing the location of each of the spans measured. Fig. 3 shows the extension across the longitudinal seam on the middle course, curve C-7 being taken at the front edge, C-11 at the rear edge and C-15 in the middle of the sheet. The author points out that in the case of a three-course boiler with one sheet to a course, as found in current construction, it would seem that a double riveted lap joint might occasion (by reason of the greater extension) an excessive stress in the solid sheet abreast the end of the seam, under certain pressures.

Pressure on the exterior of the tubes necessarily extends them in length. The amount of the extension appears to depend upon their position with reference to their proximity to the shell. Tubes adjacent to the shell extend less than those at the middle of the rows, a restraining influence from the shell appearing to affect the outer ones.

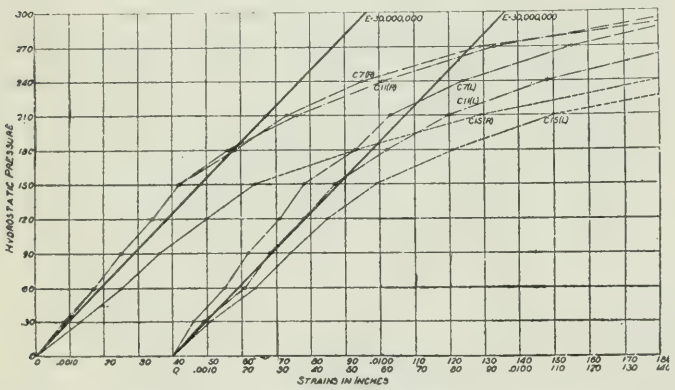

Fig. 3.—Curves of Tangential Extension, Across Longitudinal Seams, at Middle of Length of Course and at Edges.

In a plain cylindrical shell, increase in diameter would necessarily be attended by a definite amount of endwise contraction, eliminating the effect of pressure on the heads. The tests showed that there were parts of the boiler which were nearly free from longitudinal strains, while there were other places in which the strains were reversed and longitudinal extension shown instead of contraction. Along the lower quarter of the boiler the longitudinal strains were contractions, while along the upper quarter they were in part contractions and in part extensions. Figs. 4 and 5 show the amount and character of these strains at 270 pounds in the middle of the sheets and across the girth seams respectively.

It will be noticed that the lower part of the shell contracted notwithstanding the fact that the tubes were extended by the exterior pressure to which they were subjected. This behavior calls for bending at the flanges of the heads to compensate for the difference of these movements. The six through braces would relieve the shell of a portion of the longitudinal tension coming from the heads in the upper half of the boiler. Longitudinal gauged lengths on the upper part of the shell showed diminished contractions over those observed on the lower portion or displayed strains of extension. On the very top of the boiler the strains were extensions of a pronounced order.

The tests for which the figures and diagrams in the paper are given were made upon only one of the boilers. In the tests of the first boiler greater strains were displayed in the vicinity of the dome and the manhole frame than at other parts of the shell, which resulted in an early failure at these places. Actual rupture of the dome was not accomplished, but leakage along its single-riveted longitudinal seam became so great at 266 pounds that it was necessary to remove the dome and close the opening to it in the shell with a patch in order to reach higher pressures with the pump available.

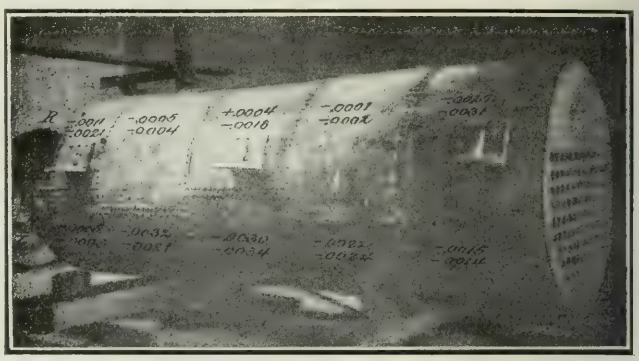

Fig. 4.—Longitudinal Strains on Solid Sheets at Middle Length of Courses. Minus Signs Indicate Longitudinal Contraction; Plus Signs, Longitudinal Extension.

At 270 pounds the cast-iron manhole frame fractured across the middle of its length. Another patch was then put on the shell covering the manhole and the test resumed, when at 295 pounds the rupture of three braces of the front head occurred. The test was then discontinued and the boiler dismantled. The strain measurements made upon the boiler were of the same order as those reported for the second and the results were similar.

A feature, however, in the test of the first boiler was absent or obscure in that of the second. Measurements of strains across the longitudinal seams increased progressively in passing from the front to the rear end of the boiler. The author says: "While these seams were not directly exposed to the heated gases over the grates, nevertheless it seems probable that a wider range of thermal conditions prevailed

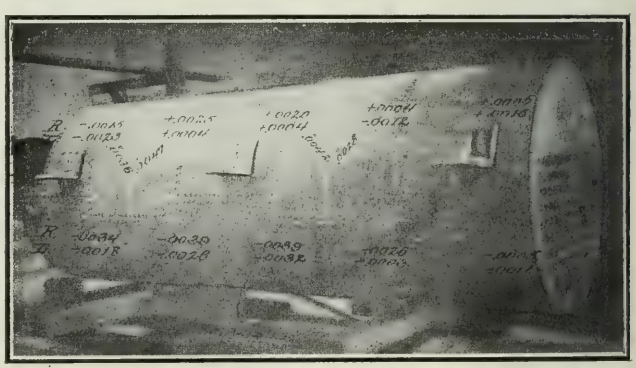

Fig. 5.—Longitudinal Strains Across Girth Seams, Also Strains on Diagonal Gauged Lengths of Courses.

in the vicinity of seams at the front end over those at the rear end of the boiler. If such was the case it would aid in explaining the greater slip of the forward seams." Leakage at the longitudinal seams began at 120 pounds and became general at 180, but at this time the slip of the joints had become pronounced and necessarily disturbed the calking.

The second boiler was stripped of its dome and manhole frame and the openings covered with patches before it was

tested. The heads were strengthened by means of six 1¼ inch through braces. The cast-iron safety-valve nozzle was allowed to remain in place, but was eventually replaced by a soft patch after 300 pounds pressure had been applied and released, as the distortion of the shell under the flange of the nozzle caused leaks impracticable to calk. During the test the boiler was supported on two wooden shoes sawed to fit the curvature of the shell.

When the pressure in the boiler was increased from 300 pounds, the highest indicated on the diagrams, to 335 pounds the manhole patch ruptured. Three of the rivets were sheared by the tangential stress of the shell followed apparently by the fracture of other rivets by tension on their stems which pulled off the heads and finally tore the sheet longitudinally along its upper element, starting this fracture at a rivet hole of the manhole as shown in Fig. 6.

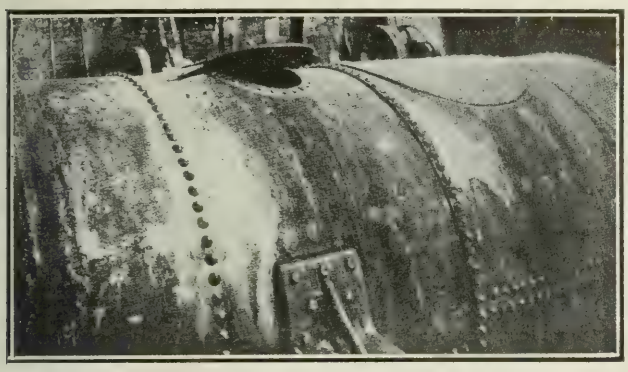

Fig. 6.—Manhole Patch After Rupture.

The shell was repaired by cutting out a portion of the middle course and putting in a section the full width of the course and about 3 feet wide measured on the arc. This was double riveted to the shell at its longitudinal seams. The hand-riveted seams extended rapidly, and copious leaks were started so that at the time of writing the paper no greater pressure than that of 335 pounds, at which the manhole patch ruptured, had been attained.

In summing up, the author points out the usual influence of longitudinal seams in intensifying the stresses in the adjacent sheets, the excessive stress developed at the side of the manhole patch and at the side of the safety-valve nozzle, and suggests that if such abnormal stresses can occur with so simple a structure as the boiler under consideration, it might be well to apply this method of examination to the strains produced in boilers of more complex construction.

GREASE IN GARBAGE.

Grease in garbage at Toronto was determined by a test made in January, 1911, at the works of Messrs. W. Harris & Company, under the direction of Messrs. Hering & Gregory, consulting engineers, of New York City. The object of the experiment was to ascertain by means of the reduction process the amount of grease contained in samples of Toronto garbage. Ten loads of garbage and rubbish, having a total weight of 11,075 lbs. were delivered at the works. This material was sorted over and the rubbish removed from it, leaving a net weight of 8,823 lbs. The garbage was then subjected to the reduction process and it was found from the results and analyses that the total amount of grease was about 4.71 per cent. of the weight of garbage. It is impracticable to recover all of the grease, but it is stated that by the use of the naphtha process the total amount of grease which could have been recovered would have been about 4 per cent. of the weight of the garbage.

COST ANALYSIS FOR CONTRACTORS.

The American Society of Engineering Contractors has for some months been working upon a uniform system of cost analysis for contractors, a committee having been appointed and discussions having been held at the monthly meetings of the society in New York and by some of the sections of the society in other cities. The subject has been freely discussed at these meetings by many contractors and a certain amount of progress is apparently being made. At a meeting in New York Edmund A. Pratt, under the title "A Simple Form of Cost Analysis," presented a form dealing with reinforcement in concrete work. This was somewhat modified by the discussion which followed, the resulting form being that shown herewith. The form presented is not intended to be kept in the field, but in the office, containing the results and total of records kept in the field. It seemed to be the general idea that the most convenient size for the form was that of the ordinary letter head, as it made it convenient for filing and for reference. As indicating the general ideas of the members concerning the subject of cost analysis we quote certain remarks from the minutes of that meeting as published in the September number of the Journal of the society:

Secretary Wemlinger—Although we have become acquainted with many and various systems and forms for cost keeping and cost analyses, few of such are sufficiently simple and convenient to become available for general use. It is our aim, therefore, to determine what features, classifications, items or subdivisions are desirable or necessary in cost analysis blanks, so that the engineering contractor who needs to study his costs can readily do so by using some of the standard forms and methods recommended and adopted by the society.

Mr. Lockwood—Concerning cost-keeping systems there is always danger of too much detail. In a certain shop a very elaborate system was put in to revolutionize the work and to show how much the owners were losing. At the end of the year they had lost $30,000; the system was so complicated with minute detail that it took half the time of the men to fill out cards.

Mr. Smith—There is a weekly time card that I saw one contractor use, something like that illustrated below:

Foreman, F. C. Burke.

Laborer, John Angelo.

Day.	7	8	9	10	11	1	2	3	4
Monday	A		C		D	C		A	
Tuesday	B								
Wednesday	D	E		A		D			C
Thursday	C								
Friday	E					D			
Saturday	B	A		B			E		C

At the top of the card is written the foreman's name and the name of the laborer. The first column is for the day, there being six spaces, one for each day of the week. Across the top, under the names, are printed the working hours. In the morning the foreman would take the card for each man and write a capital letter to indicate the class of work that the man was working on; later, say nine o'clock, if he changed him to another class of work, he would write another letter in the column 9. Every time the workmen were put to work on some other part of the job the proper classification letter was entered in the time column. . . . The foreman took the cards from the men every morning at seven o'clock and kept them in his pocket until noon, when he handed them back to the men. Then at one o'clock he took the cards back and entered the proper classification of work for each man. At five o'clock the cards were handed back to the men, and the whole thing repeated each day.

Mr. Wake—We find that the finer we try to get the records the more inaccurate they are. If you give the contractor too much to keep track of he cannot, or will not, do it.

Mr. Wemlinger—The object of cost keeping is not like that of book-keeping, to itemize everything to cents, but to get an approximate idea of the various costs. That is what we aim to do.

Mr. Wake—A contractor could not afford to keep these records if we go into too much detail.

Mr. Wemlinger—The large organization can afford to keep them, but we want to devise blank forms for the fellow that cannot afford to keep a man busy keeping track of all these details. We want something for the contractor who may have to do all this work himself.

Mr. Watson—The efficiency of any system of cost analysis depends, in the first place, on the accuracy of cost records. To serve the purpose well these must be clear and reliable and the conditions of the work concisely explained. Furthermore, the items of cost should be kept in accordance with some uniform system, so that records of different jobs may be compared intelligently and used advantageously in the analysis of costs for future estimates.

To get costs and to make the proper distribution on the records should be the duty of one man alone. If this man is shown what to do and how to do it, where and what changes to make, and is on the job all the time, keeping a journal and photographs as well, then at the end of a job these records are worth something; but ordinarily the timekeeper simply makes the easiest distribution he can and gives no details.

By watching the reports I myself know what job needs my attention most and when. Some contractors say: "The job is not large enough to pay the costs of a clerk." This is the biggest mistake possible, for every job will pay a clerk's wages. If you are losing money have him more than ever, for the records will show what the loss is and the reason why, and you can avoid making the same mistake again. My experience is that foremen and assistant superintendents who keep good cost records are not fit for anything else, as a rule, and could not get the work done for the estimated cost. For that reason, I say emphatically, have a cost clerk on every job; the better the man the more money you will make in the end.

In a discussion by the Indianapolis section of the report of the Committee on Uniform System of Cost Analysis considerable time was devoted to discussing the possibility of utilizing the facts obtained by such analysis in preventing the recognized evil of the low bids submitted by inexperienced contractors, which bids are too often accepted to the injury of both the contractor and the city or other party for whom the work is done.

The distinction between productive and non-productive labor and material was made a point of discussion also. In connection with the discussion DeWitt D. Moore, chairman of the committee, called attention to the committee's chart wherein it was endeavored to classify the several items of cost in a general way, this having formed a part of the report of the committee at the first meeting in 1911.

Mr. C. Brown said:

As a result of the speaker's experience in keeping final records of costs of additions to existing plants, such as sew-

ers, waterworks, and the like, in which distinctions must be between new construction and maintenance and repairs, he strongly urges the separation of items on the basis of productive and non-productive labor and material. The separation is made quite generally in the schedules offered in the committee report and in Mr. Luten's discussion of the same, but incidentally rather than upon a fixed principle. It may, therefore, help to point out this principle in order that it may serve as a guide to determine the method of handling the details.

The distinctions between the above two classes of labor and material are as follows:—

1. What might be termed productive material and labor, to borrow the term without modifying it to fit the facts exactly, is material that remains in the work and forms a permanent part of it, and labor which puts that material in its place and keeps it there.

2. Non-productive material and labor figuratively speaking, consists of tools, equipment, etc., used in handling the material put into the work and in holding it in place temporarily; such non-productive material being then removed permanently from the work, thenceforth to have no further conection with it. Non-productive labor is the labor which is put upon this non-productive material, in preparing it for use, in disposing of it, transporting it, etc.

3. There is also the usual class of non-productive labor, i.e., labor which has no direct effect in putting the materials into their positions in the structure.

*To be proportioned over the various items of productive labor.

CEMENT STRONG ROOMS.

In a recent English test of the burglar-proof qualities of vaults of reinforced concrete, a slab of the material six inches thick was perforated with a hole 3½ inches in diameter by means of the oxyacetylene blowpipe. When a steel bar was reached, it was instantly fused away by directing a jet of pure oxygen on the white-hot metal, but this metal-cutting jet had little effect on the concrete.

The time required for making the hole was 24 minutes. As a similar hole in any kind of steel could be made through an equal thickness within four minutes with the jet, it was evident that the concrete offered an important advantage for strong-room building.

SHALLOW FLOORS FOR RAILWAY BRIDGES.*

By O. F. Dalstrom.

In railway bridges of the through type, designed for crossings where local conditions do not govern the depth of the floor system, that depth is determined by sections that give the greatest economy of material consistent with simplicity of construction and facility of erection.

The Shallow Trough Floor Bridge.—The floor beam usually determines the depth of floor in designs of open floor through bridges, whether truss or plate girder type. The term "depth of floor" will be used throughout this discussion to indicate the distance from base of rail to lowest steel of span. If considerations governing the design of the trusses produce panels of considerable length, the stringers, instead of the floor beams, may determine the depth of floor. A single track truss span of 350 to 400 ft., with trusses 18 ft. 6 in. or 19 ft. centres, may have panels over 30 ft. in length. In such a design the economical depth of the stringer would be about the same as that of the floor beam. In common practice the floor beam would still be made deeper than the stringer to obtain simple details of connection between these members.

But conditions of grade and requirements of clearance below the bridge may make it necessary, in a measure, to disregard economy of material and simplicity of construction and erection to obtain designs that will meet all the requirements in special cases. Difficult conditions of grade under clearance, necessitating extreme shallowness of floor, are frequently encountered in crossings over streets and over other railways; and the type best adapted to any particular crossing must be determined by a careful study of the local conditions.

A crossing over another railway usually requires that the grades be carried above the normal grade of the line, with a through bridge over the railway at the apex of the grades. If the approach grades are long and heavy, the slightest reduction in the depth of the floor of the bridge means an appreciable reduction in the cost of the approaches. And—what may be of greater significance than the reduction of the cost of bridges and approaches—it means the reduction of grades that would be costly and otherwise objectionable, or practically impossible, from the standpoint of operation, where local conditions determine the limit of running out of the grade.

The files of the bridge department of the C. & N. W. contain the plans of a large number of bridges that have been designed to meet extreme conditions of clearance grade and curvature. A few of these designs have been selected, with special reference to shallowness of floor, as typical. Fig. 1 shows the floor details in the design of a double track through truss bridge of 170 ft. span, in which the depth of floor is 1 ft. 11 in. This bridge is designed for Cooper's Class E-50 locomotive; or a concentration of 60,000 lb. on each of two axles spaced 6 ft. 0 in. centre to centre.

The floor is of trough construction, the troughs being placed perpendicular to the axis of the bridge. Each trough carries a tie under each track, as shown in transverse section through troughs and floor beams in Fig. 1; the tie is supported at four points on horizontal angles riveted to the tops of diaphragms extending between the webs of the troughs. In every alternate trough, except those adjacent to the floor beam, special diaphragms are provided near the ends of the ties. To these diaphragms the ties are anchored by bolts

*A paper before the Western Society of Engineers, December 13th, 1911.

through the horizontal angles at the tops of the diaphragms, which are so located in the troughs that the bolts will be about 4 in.—a convenient working distance—inside the guard rail. The horizontal legs of the angles at the tops are turned toward the ends of the ties to make the bolts accessible after the ties are put in place. The tie bolt diaphragms are omitted in the troughs adjacent to the floor beams, as they would interfere with the driving of the field rivets at the ends of these troughs.

The troughs (half-section, B-B), are carried by longitudinal girders which are parallel to the trusses, and placed at a sufficient distance from the lower chord to permit ready inspection of the chord and girder. The longitudinal girders are carried by the floor beams (half-section A-A), which are designed to receive the entire panel load and transmit it to the truss.

The troughs are designed to carry a concentration of 60,000 lb. on each track, each concentration distributed over two ties. This gives a load of 30,000 lb. on each of the two ties carried by the trough, or 60,000 lb. carried by the trough. The floor beam is designed to carry the load from the intermediate troughs, concentrated at the bearings of the longitudinal girders, 2 ft. 1 in. from the centre lines of the trusses; and, in addition, to carry its part of the load on the ties in the adjacent troughs.

The heavy load carried by the floor beam, together with its greater length, requires in this member a section considerably heavier than that of the troughs. The depth back to back of angles is made the same in the floor beam and troughs, but the addition of flange material required to give the necessary section modulus in the floor beam, makes the extreme depth of this member somewhat greater than that of the trough sections. This extreme depth of floor beam determines the depth of floor for this type of bridge. By flattening the rivets under the rail and allowing a clearance of 1 in. from the base of rail to the tops of the flattened rivet heads, a satisfactory section is worked out with a depth of floor of 1 ft. 11 in.

It will be noticed that the material in the floor beam and trough sections is not disposed symmetrically with reference to a horizontal line at the middle of the section. In order to obtain the most effective distribution of material, the neutral axis is maintained at the middle of the section. The metal is increased on the tension or lower side to make up for the reduction of section by rivet holes, no allowance for reduction of section by rivet holes being necessary on the compression or upper side of the section.

The depth of the longitudinal girders is made considerably greater than economic considerations require for the section. This is done to obtain a good detail at the end bearing and at the connection to the floor beam.

Fig. 1.—General Details of Shallow Trough Bridge Floor.

The top flange of this girder is unsymmetrical, being composed of a plate and an angle, the angle placed with its face against the web, the horizontal leg projecting over the top of the web and outward from the track. This detail of the top flange is to gain an additional horizontal clearance, as at this point the structure approaches nearer to the clearance diagram than at any other place except at the end post, where the edge of the cover plate is coincident with the extreme vertical line of the clearance diagram. An advantage in erection is also obtained by this detail of top flange section, as it permits setting the trough sections in place on the bottom flanges of the girders, with only a very slight displacement of the girders from their permanent position.

To further facilitate erection of the troughs, the stiffeners are omitted from the inner side of the longitudinal girder. The end connection angles of the troughs, which are field riveted to the web of the girders, are placed high enough so that the tie bolt diaphragms near the ends of the troughs will not interfere with the driving of the field rivets at the ends of the troughs in which the tie bolt diaphragms occur.

The troughs are drained through 1 in. gas pipes fitted into holes in their bottoms and projecting slightly below the trough to form a drip. This projection of the drain pipes must not extend below the line of low steel determined by the rivet heads on the under side of the extreme cover plate of the bottom of the floor beam. The upper ends of the drain pipes are threaded into washers to hold them in place. The lower part of the troughs is filled with asphalt mastic, the surface sloping toward the drain pipes and flashed over the washers at the upper ends of the pipes. A layer of broken stone covered with gravel is spread over the mastic for a protection.

sections. There is no interference from the girder in driving the rivets on the outside of the truss, but these rivets, up to the level of the tops of the girders, should be driven at the same time that the riveting on the opposite side of the truss is done.

In the development of this type of shallow floor for double track bridges, the first efforts were directed toward obtaining an open floor design, with stringers beneath the track, transmitting the load directly to the floor beam. The excessive bending moment in the floor beam, resulting from this arrangement, made it impracticable to design a floor beam that would come within the required limits of depth of floor.

Following this, a trough floor type was designed, differing from the one shown on Fig. 1 in that it had no longitudinal girders to carry the troughs. Instead, the troughs were extended to the trusses and connected to the bottom chord in the same manner that the floor beam in Fig. 1 is connected to the chord at the panel point. The bottom chord was designed to act as a girder, to carry the panel loads to

33'6" Out to Out of Girders

Fig. 2.—General Details of Shallow Open Bridge Floor.

The deflection of this floor under a maximum load is considerably greater than that of floors designed for depths determined by economical sections. Under maximum load the theoretical deflection at the centre of the floor beam is 0.65 in. The erection of truss bridges of the open trough floor type requires a special order of work in riveting, owing to the longitudinal girders being located so close to the trusses. After the girders have been placed in position, no riveting can be done on the inside of the lower chord opposite the girder. On this account all riveting in the trusses below the level of the tops of the girders must be done before the girders go into place, which means that all lower chord splices, floor beam connections to trusses, and web member connections to gusset plates, up to the level of the tops of the girders, must be riveted before placing girders and trough

the panel points. This design brought the depth of floo within the required limits, but made the troughs excessively heavy. The bottom chord was necessarily made deep and heavy, since it had to act as a beam for the floor troughs at the same time that it was doing duty as a tension member in the truss.

The next step was the introduction of the longitudinal girder. This was placed as close to the track as the clearance diagram would permit, to reduce as far as possible the bending moment, and thereby the sections, of the floor troughs. The introduction of the longitudinal girder changed the bottom chord from a combined beam and tension member to a simple tension member, and eliminated from it the objectionable secondary stresses produced by the vertical loads applied at the trough connections.

Below are given a few figures for the comparison of a 170 ft. double-track span of the above type, and a double-track span of the same length, with the usual open floor construction, in which the floor beam and stringer sections are determined by the economical depth.

	Shallow trough floor type.	Deep floor type.
Depth of floor	1 ft. 11 in.	4 ft. 9 in.
Weight of floor system per lineal foot of bridge	5,000 lb.	1,700 lb.
Weight of trusses and bracing, per lineal foot of bridge	3,400 lb.	3,250 lb.
Weight of 170-ft. span, complete	1,496,000 lb.	900,000 lb.
Total cost of span, f.o.b. cars at bridge company's plant, at $0.025 per lb.	$37,400.00	$22,500.00

Difference, $14,900.00 = 66.2 per cent. of deep floor type.

As the depth of floor is increased, the weight diminishes rapidly. At 2 ft. 4¼ in. depth, the weight is 4,100-lb. per lineal foot of bridge. Further increase of depth would show a corresponding decrease in weight until the minimum thickness of material in sections is reached.

Unit prices in bids submitted by bridge companies for the fabrication of material for the shallow trough floor type have been found to run about the same as those submitted at the same time for open floor truss bridges. On this basis, a comparison of the two types of the span selected shows that the shallow floor type would cost, f.o.b. cars at bridge company's plant, about 66 per cent. more than the deep floor type. The cost per ton for erecting would be about the same for both types. The number of field rivets per ton is somewhat less in the shallow floor type than in the other type; but an allowance, for which no figures are at present available, must be made for the order of procedure in riveting, which requires that part of the riveting be done before all the material in the bridge is assembled, and for the additional falsework and blocking that are necessary under the floor system to provide for the uninterrupted movement of the trains.

The comparison of costs of the two types erected would show about the same relation as that of the costs of fabrication.

The range of application of floors of this type in double-track truss bridges would cover depths of floor of about 3 ft. and under, if the panel lengths do not exceed 15 ft. With a depth of floor over 3 ft. an open floor bridge is practicable and would be more economical.

For double-track through girder bridges, where panel lengths can be varied as desired, the application would be limited to about 2 ft. 6 in. depth of floor.

The Shallow Open Floor Bridge.—A design of open floor, double-track bridge, with 1 ft. 6 in. depth of floor is shown in Fig. 2. This is the plan of a bridge erected near Mapleton, Wis., on the new line of the M. S. & N. W. The design shown is for a double-track bridge, but the type is applicable to crossings with any number of tracks at the standard distance of 13 ft. centres. The limitation of this type of bridge is in the direction of span lengths, being suitable only for spans of less than 40 ft.

The relation of the clearance diagram to the girders shows that in the longer spans the girders and not the floor beams or stringers determine the depth of floor. The section of the middle girder, which carries load from both tracks, is exceptionally heavy, while that of the floor beams have no shapes over ⅝ in. thick. In shorter spans, 20 to 25 ft., it would be possible to make a shallower girder and reduce the depth of the floor beam so that the depth of the floor would be about 1 ft. 3 in. At that depth the stringer would be so shallow that any further attempt to reduce the depth of floor would result in stringers so shallow and short, and floor beams so close together, that the floor would consist of floor beams connected by diaphragms acting as stringers. It would be approximating the type described above under the name of shallow trough floor bridges.

In spans of 15 ft. or less, the girders can be brought under the third offset of the clearance diagram, making the floor beams shorter and lighter. At this point the depth of floor would probably be determined by the stringer, and the floor beam would be designed in accordance with that depth.

The Rail Girder.—Fig. 3 is the plan of a girder designed to carry a track over a 4 ft. 6 in. clear span in places where there is not sufficient space for stringers and ties below the rail. Conditions requiring such designs are not uncommon in railway yards and in city streets, where pipes and conduits are laid close to the grade of the track.

This design consists essentially of an independent girder for each rail, built up of Z shapes and bars. Section E-E is a transverse section of the girder, showing the rail held in place by cast iron clips bolted to the webs of the Z's. The depth of floor is 3 in., using the term in the same sense as in the discussion of the previous tvpes.

In the design of the girder it is assumed that both rail and girder will be effective in resisting the bending under load. They will act as separate units, however. Both rail

and girder will be deflected the some amount, but as they are of different sections, the stresses in the extreme fibres will not be the same, but will be proportionate to the distance of the extreme fibre from the neutral axis in each case. This distance in the girder is 3 in. In the rail shown it is 2⅞ in., or 0.96 of that of the girder.

The section modulus of the girder given below, Section E-E, is the actual section modulus of the net section of the girder. The "effective" section modulus given for the rail is 0.96 of the actual section modulus of the rail. The sum is the effective section modulus of girder and rail acting as separate units, and deflected the same amount.

Section E-E shows a 90-lb. A. S. C. E. rail section, on the girder. Any type of rail can be used with the girder by varying the details of the cast iron clips to conform to the section of the rail to be used. The space in the girder on each side of the rail is filled with asphalt mastic, to protect the steel and provide a run off for drainage.

The weight of a pair of girders of the section shown in section E-E is about 1,500 lb. The weight of a pair of the special section is practically the same as that of the standard section.

CONCRETE CONSTRUCTION.*

By E. Brown, Professor of Applied Mechanics and Hydraulics at McGill University.

Concrete construction has many followers, ranging from the rabid enthusiast who will assert that it is the thing for almost every kind of building, to the more modest and perhaps more effective advocate who realizes at one and the same time its advantages and its limitations. There was a day when it had its opponents, but its record of actual achievement in the past few years has established its claim to being one of the principal forms of construction at the present day. The opponents have become friendly critics or even converts, and I imagine there are now very few who are so blind as to ignore the facts of the situation. There are, however, some who seem to think that a designer in reinforced concrete is drawing on his imagination (shall I say) to a much greater extent than a designer of steel work. Some steel designers, at all events until recently, would almost give you the impression that their work was calculated to such a nicety as compared with that possible in reinforced concrete work, that the latter by comparison had very little claim to exactitude. I am not here advocating one form of construction as against another, nor any particular type of either form, but I do say that if we set down the exact conditions of the problem confronting a designer in these rival forms of construction, there is not much to choose in the matter of exactitude. I am not here concerned with any considerations of actual construction. We can have good and bad work in any kind of construction. I am speaking of the conditions of design. The problem is always this, no matter whether it is a design for a huge bridge or for an office building or store.

(1) To make some estimate, more or less exact, of the forces which will probably be brought to bear on the structure considered. Floor loads, wind loads, etc.

(2) By some theory, more or less exact, to determine the forces which the above estimated loads will produce in the component parts of the structure.

(3) From our knowledge, more or less exact, of the physical characteristics of the materials employed in the various parts of the structure, to so proportion those parts that they may withstand successfully for an indefinite period, the forces which are estimated to come upon them.

After that it is necessary to have the work carried out in strict conformity to the designers by efficient labor, under the best supervision. In the matter of the first two processes above, designers of steel work and of reinforced concrete work are on the same footing.

As regards the third point, our knowledge of the properties of concrete, and of the effects of changes in its composition is now of considerable extent, and I do not think that a conservative designer need have any anxiety in regard to the behavior of his structure if reasonable, sound specifications are lived up to. Steel designers, in recent years, have come to consider much more carefully than heretofore, the probable effects of eccentricity in some of their details, and in this, reinforced concrete designers can learn from them. In the particular case of columns consisting of angle and other sections latticed and tied together, we are only in the early stage of finding out how they really act. I could show you experimentally the actual conditions of stress in such a member as a tie bar made up of two angles, back to back, connected by a plate at their ends, and separated at intervals by distance pieces—one of the commonest forms of construction imaginable. Experiments of a very interesting character are being made by one of our staff at McGill on this matter, and all I need say to emphasize the point I am now making, is that any steel designer who thinks that even such a simple built up member acts as one piece has another "think" coming to him. No, gentlemen, we are all engaged in "estimating" something. Formulae expressing the complex action which is going on in either a steel structure, or in one of reinforced concrete may be forthcoming, but of this I have grave doubt, and even if they are, we shall, for practical purposes, make such modifications of them as will eliminate from them any complexities which are due to effects which are either of small magnitude, or which can be allowed for in a simpler manner.

A survey of the development of our professional work generally will show that whenever and in so far as it has been possible to exalt any branch of that work to the rank of a science, the progress has been due to the gradual but certain development of a few fundamental ideas. Our great electrical industries of to-day have developed by applications of the great principle discovered by Faraday when he found that a closed coil of wire moved across a magnetic field generated an electric current. And while few of our branches of engineering science are as scientifically exact as the one I have just mentioned, in all or most of them there is such a mass of practical experience and of results of tests to couple with some simple fundamental ideas expressing actual conditions but inadequately, that we can go ahead with our designs with complete confidence in the results. The science of hydraulics is an instance of this phase of the work of our profession.

So that while I for one would not be prepared to admit that the steel designer can figure the actualities to a much finer degree of accuracy than the reinforced concrete designer, I do think that the latter depends to a tremendous extent on the honesty and sincerity with which his plans are carried out. Structural mild steel is manufactured in our steel mills under reasonably uniform conditions, and speaking broadly of course, an engineer buys it in the open market with considerable confidence in its physical properties. He knows that he can figure safely on 16,000 pounds per square inch in tension, and that if he is cutting his sections as finely as possible, he may reduce them by say 10 per cent. and increase his unit stress accordingly. The properties of his material are not altered. He is **not** taking an **unknown** risk.

But in concrete construction the material by which the compressive forces in the structure are carried is made and laid on the spot and is liable to such variations in mixing as may occur in practice quite apart from any variations in quality due to change of composition. If we reduce cement by say, 10 per cent., use an inferior sand, or change the nature of the aggregate without definite knowledge of the effects of this change—if we do all or any of these things we are altering to an uncertain extent the physical properties of our concrete. We **are** taking an **unknown** risk, and one which to my mind is entirely different in character from that involved in a cut of a definite per cent. on steel sections. We know from experience that certain expectations in the properties of mild steel will almost certainly be lived up to, and it is in the power of those engaged in reinforced concrete work to produce a concrete equally uniform and reliable. A successful designer has always in mind certain possible differences between assumed and actual conditions, and it is in a proper realization of such differences, and in the capacity of the designer to apreciate the extent of their influence, that reliance must be placed. If for any reason he may fear that the concrete will only stand a compression stress of 400 pounds per square inch, instead of perhaps 600, his oppor-

*Abstract of paper read before Montreal Builders' Exchange.

tunities to make both a successful and economical design are at once limited. Poor concrete is much the same weight per cubic foot as good concrete, and if the concrete is poor, and only capable of safely carrying a small compressive stress, more is required to sustain a given compression load, and hence, more steel is required to carry the extra dead load necessitated. But we **can** get uniformly high grade concrete if proper care is exercised. At the same time the calculation of a designer can be rendered of little avail if the actual work is not carried out in a thoroughly conscientious manner.

Any theory of reinforced beams starts from the assumption that the several layers of the beam are lengthened or shortened by an amount proportional to their distance from the plane separating tension and compression areas. Careful experiment shows while this is not rigidly true in all cases, it is conformed to with reasonable accuracy in most cases. Accepting it as true we shall get different results for the bending moment which the beam can carry according as we assume.

(a) Variable modulus following assigned law.

(b) Modulus uniform during loading.

(c) Different values for uniform modulus.

Assume a rectangular beam 10 inches deep with, say, one per cent. reinforcement. Then, taking average concrete, one should find that under working loads the distance from the steel line to the point in the section where the resulting compression acts is about 8 feet 6 inches if we assume a variable modulus with the definite law of variation; 8 feet 8 inches if we assume a uniform modulus of 3×10^6 pounds per square inch.

The safe bending moment on the beam is the product of the allowable force in the steel and one or other of the above numbers. It is evident that the difference shown in the safe bending moments is only some 2½ per cent., and any attempt to figure to such a degree of supposed accuracy is foolish. Rods, in practice, may easily be displaced by an amount affecting strength of calculations far more than do these different theories.

These figures neglect concrete tension and their differences indicate the extent to which different methods of calculations affect the broad features of design. Under the specifications adopted by the American Society for testing materials, the American Society of Civil Engneers, and the Maintenance of Ways Association, all concrete is now taken to have the same modulus, a great change since the days when cinders, rock concrete, gravel concrete, etc., were all supposed to have a different modulus, and following a different law of variation as the load increased. It has been amply demonstrated that all these were unnecessary refinements and the standard specifications recently drawn up have swept them away. Similar simple specifications were drawn up earlier by the Royal Institutes of British Architects, and I would urge the adoption of some such standards here. I do not believe you have any such standards at present. When in Toronto a couple of years ago attending the Cement Association Congress I learned that their buliding by-laws prohibited a designer from figuring any continuity in reinforced concrete floor systems, and I believe that foolish and unjustifiable prohibition still stands. It seems to me to eliminate competition to a great extent and to leave a clear field for the steel construction. Here, in Montreal, I do not think you are hampered by any by-laws on such matters—it is more of a go-as-you-please. You are more familiar than I can be with the results of this, but unless something miraculous happens, the usual result of such conditions is to find one design called for according to one set of specifications, another design according to another set, and so on. Now, even if all these varied specifications are beyond reasonable criticism—which is questionable—would it not be better to have a working standard? Our railroad bridges and highway bridges are built under standard specifications, and it seems to me desirable that there should be some standards in this matter also. I am sure it would be advantageous to have something of the kind, whether the architect prepares the plans in his own office or has them prepared independently by an outside firm.

PATENTS AND THE ENGINEER.

The following is the outline of an address delivered to the Engineers' Club, of Toronto, on Thursday, January 11th, by Mr. J. E. Maybee, patents solicitor of Toronto.

The main purpose of the address was to point out to prospective inventors the proper course to follow if they wished to avoid the more common pitfalls which beset the inventor's path. The great inventions, outside a few lucky hits, are not made by men who sit down with the idea of inventing something but in response to the stimulus of a known want.

An inventor who succeeds with the least waste effort will follow fairly closely the following order of procedure, which is given substantially in the lecturer's own words:

1. Find a want, i.e., be sure you have a market. It pays to devote the utmost care to gauging the needs of your public.

2. Be sure you have, or can acquire, a sufficient quantum of knowledge to enable you to direct your efforts wisely.

3. Obtain as wide a knowledge as possible of the inventions of others along similar lines. (Some in practice do this just before taking step No. 6.)

4. With sweat of brain evolve a new idea and embody it in concrete form.

5. Devote every effort to **work out your details** as thoroughly as possible, so that your device will not only work well, but what is just as important, **can be easily and cheaply made.**

One of the most fruitful fields for inventors lies in devising means for more cheaply making various articles of manufacture or in devising simplified forms of commonly used articles or machines.

6. See that you get as good a patent as can be obtained.

In both patents and inventions "pretty near is not good enough." In a recent address before the Engineers' Club, of this city, Mr. Justice Riddell pointed out that failure to keep the above maxim in mind led to such disasters as the Austin dam failure, and unless the inventor would court failure he must make "as good as possible" his motto, and he should select professional advisers who will live up to the same rule.

It was pointed out that engineers, as a rule, did not figure largely as patentees, the exceptions being those specially employed by large concerns to perfect their goods or machinery.

The main reason given for the lack of inventiveness of the engineer was the necessary conservatism of his procedure in his work, whereas the disposition of the typical inventor was to exhibit a contempt for authority and tradition.

A strong plea was made to the engineering student to acquire as broad a general culture as possible and to cultivate the imaginative faculty which in essence is the same in the artist as in the engineer, and which is one of the most useful and prominent characteristics of a successful inventor.

THE DESIGN OF TALL CHIMNEYS.*

By Henry Adams.

Architects, in the course of their practice, have frequently to furnish designs for special constructions, and although they sometimes adopt the sensible course of calling to their aid the services of an expert, they more frequently draw out what they think ought to do, and place the responsibility upon the contractor. The present condition of general knowledge upon the subject of the stability of tall chimneys is strikingly shown in connection with the Mechernich shaft.† This was designed to withstand a wind pressure of 160 lb. per square foot; Prof. Rankine calculated that it would stand only 70 lb. per square foot, while Mr. R. J. Hutton, a later writer, estimated that a wind pressure of only 32 lb. per square foot over the whole height would be sufficient to damage it. Tall chimneys ought to be designed upon scientific principles, so that there is an absolute guarantee for their stability, and in the following paper the author desires to elucidate these principles.

Height.—In designing a tall chimney‡ it is desirable first to know what height to make it. Forty-five feet is an ordinary height to serve two steam boilers, but in some

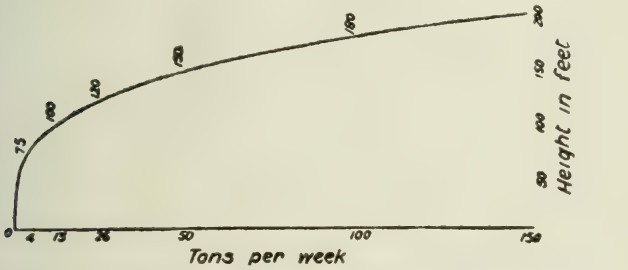

Fig. 1—Height of Chimney According to Consumption of Coal.

towns, as Manchester and Leeds, 90 ft. is the minimum allowed. They are sometimes proportioned for height according to the coal burnt per week of fifty-six hours, thus:—

4	tons	per week	=	75 ft. high.
13	"	"	=	100 "
26	"	"	=	120 "
50	"	"	=	150 "
100	"	"	=	180 "
150	"	"	=	200 "

This table is checked by the graphic curve shown in Fig. 1. Another rule is to make the height of the chimney three times length of boiler + twice distance of furthest boiler to chimney. This allows 1 ft. of height for every foot the gases travel round the boiler and 2 ft. of height for every foot of external flue. And again, a round chimney should not exceed twenty-five times its internal diameter in height. In many modern power stations Babcock & Wilcox boilers and Green's economizers are used; what is saved in obstruction in the boilers is lost in the economizers, so that no material difference arises, but the chimney shafts are, as a rule, only from 75 ft. to 100 ft. high, and of very large sectional area. For chemical works, or where poisonous fumes are emitted, they should be higher than for ordinary steam boilers, in order to disperse the fumes at such a height that they may be diluted to a harmless condition by the time they reach the ground. The Townsend chemical works chimney at Glasgow is 454 ft. high, and was, when built, the highest in the world.

Sectional Area.—The sectional area or internal diameter is the next point to decide, and there are many different rules, some depending only upon the coal consumption, others upon the firegrate area, and others upon the water evaporated in a given time. Simple approximate rules are:

(a) 1 sq. ft. area for each cwt. of coal burned per hour.

(b) Area = one-tenth of the total firegrate area, each flue being one-fifth of its firegrate area, and main flue one-eighth of total.

(c) 2½ sq. in. per indicated horse-power of the engine.

(d) If the height of the chimney is taken into account, as of course it should be, then on the average—

$$\text{area} = \frac{\text{lb. of coal burnt per hour}}{12\sqrt{\text{height in feet}}}, \text{ or } \frac{\text{fire-grate area sq. ft.}}{1.5\sqrt{\text{height in feet.}}}$$

Shape.—The necessary sectional area being obtained, it should next be decided whether the chimney is to be round, octagonal, or square. It is generally acknowledged that circular chimneys have the best appearance, at least above the pedestal, which is usually square, and from which the circular part springs by broached angles. Octagonal chimneys have the next best effect, some even consider that they are more sightly than round chimneys, while square chimneys always look more or less heavy, and are only suitable for short stacks of large area, such as are generally used in modern central station work. The circular chimney is most efficient for its area, as it takes the least material and there are no angles in which soot may cling; but with any chimney it is desirable to add 2 in. all round to the calculated minimum area to allow for friction. Octagonal chimneys require special bricks for the angles in alternate courses, to produce the best work.

Wind Pressure.—The comparative efficiency according to the shape of cross-section may also be considered from the point of view of obstruction to the wind, that which offers the greatest obstruction requiring the greatest stability or quantity of material apart from other considerations. It is not yet definitely settled what is the pressure of the wind upon a plane surface due to a given velocity, and still less

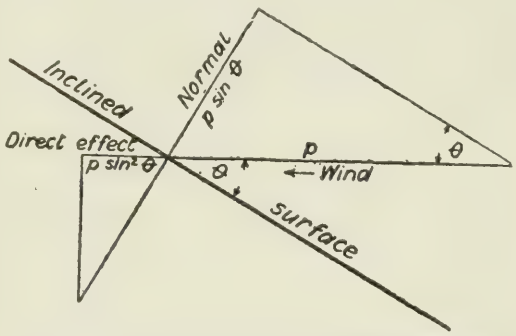

Fig. 2.—Effect of Wind on Inclined Surface.

is known of the effect upon a surface inclined to its direction. We shall generally be quite safe, however, if we allow for ordinary purposes a pressure of 56 lb. (or ½ cwt.) per square foot on a plane surface normal to the direction of the wind, and even half of this may be sufficient in many cases. When we come to fix the value of these figures against an inclined or curved surface we find much difference of opinion and no sufficient experimental evidence.

* Paper read at a meeting of the Society of Engineers, England.

† Trans. Soc. Eng., 1887. Paper by R. J. Hutton on "The Stability of Chimney Shafts."

‡ In different districts this would be known as a high chimney, mill chimney, chimney shaft, chimney stack, chimney stalk, smoke stack, furnace shaft, boiler shaft, etc.

A formula agreeing closely with Hutton's experiments* is:—

$$P = ap(\sin\theta)\ 1.84\cos\theta$$

where P = total pressure in lb.
a = area of surface in square feet.
p = normal pressure lb per square foot.
θ = angle of incidence.

and this is the basis of the majority of tables of effective pressures; but Hutton experimented on a surface only 22 sq. in. area, which was too small to be of much practical value.

Some years ago† the author suggested a variable allowance according to the width and height of the structure, would cover all cases and be more in accordance with modern experiments. His empirical formula for this purpose is now:

$$\log p = 1.125 + 0.32 \log h - 0.12 \log w$$

where p = ultimate wind pressure in lb. per square foot necessary to be allowed for against a plane surface normal to the wind,
h = height in feet of centre of gravity of surface considered, above ground level,
w = width in feet of part to be taken as one surface,

and when the surface is inclined at θ degrees to the direction of the wind, the ultimate pressure normal to the surface may be taken as $= p \sin\theta$, or its effect in the same direction as the wind $= p \sin^2\theta$ (see Fig. 2).

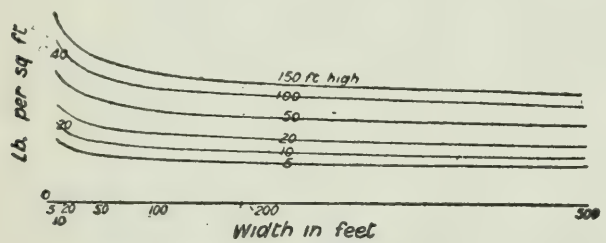

Fig. 3.—Wind Pressure According to Width and Height.

This would give allowances as in the following table, for which the curves are plotted in Figs. 3 and 4.

Wind Pressure Lb. Per Square Foot on Plane Surface.

(For very exposed positions 25 per cent. may be added.)

Height	Width in feet.						
in feet.	5	10	20	50	100	200	500
150	54.6	50.3	46.3	41.4	38.1	35.1	31.4
100	48.0	44.2	40.7	36.4	33.5	30.8	27.6
50	38.4	35.4	32.5	29.1	26.8	24.7	22.1
20	28.7	26.4	24.3	21.7	20.0	18.4	16.5
10	23.0	21.1	19.5	17.4	16.0	14.8	13.2
5	18.4	17.0	15.6	13.9	12.8	11.8	10.6

Multipliers for Angle.

θ	10	20	30	40	50	60	70	80	90
Sin	.174	.342	.500	.643	.766	.866	.940	.985	1
$\sin^2$	.0303	.117	.250	.431	.587	.750	.884	.970	1

In the case of a boundary wall the length to consider would be a portion equal to, say, one and a-half times the height, or the width between the buttresses. In the case of a roof the distance from centre to centre of the trusses should be taken, unless the stability of the whole structure be under consideration, when the full length should be taken. In the case of a lattice girder bridge 50 per cent. should be added to the actual area offered to the wind and both girders taken.

* See paper by the author on "Wind Pressure on Roofs," read before the Society of Architects, March 14, 1893.

† See discussion on a paper by R. J. Hutton on "The Stability of Chimney Shafts," Trans. Soc. Eng., 1887.

The lower part of the above table, shown graphically in Fig. 5, gives the multipliers for angle when the surface is not at right angles to the direction of the wind, the sins being used for obtaining the normal pressure on an inclined surface such as a roof, and the $\sin^2$ for the effective pressure in the same direction as the wind on such a surface as a square chimney placed diagonally.

Theoretically, account should be taken of the effect of the batter in determining the wind pressure on a chimney, but this is so slight that it may usually be omitted.

Pressure on Square Chimney.—A square chimney will give the same resistance whether facing the wind or standing diagonally to its direction, the greater area of the inclined surface and the reduced pressure upon it making the same total as the flat side under the full pressure.

Pressure on Circular Chimney.—With circular chimneys a very serious difference of opinion exists as to the effective pressure of the wind, as shown by the following list of multipliers recommended:—

Rankine.	=.5	Prof. Hutton	=.66
Wilson.	=.56	Gaudard.	=.66
Borda.	=.57	Bressé.	=.78
Sir B. Baker.	=.57	Adams.	=.7854

"Molesworth's Pocket-Book" says somewhere (but owing to the very imperfect index the author has been unable to find the statement again) that "the pressure of the wind upon a cylindrical surface has been given at one-half to two-thirds

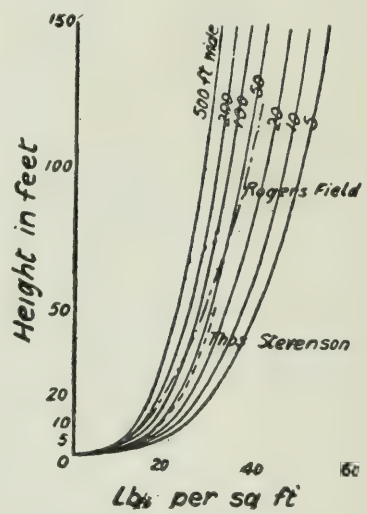

Fig. 4.—Wind Pressure According to Width and Height.

of that against a normal plane, while experiments show it to be nearer three-quarters." C. B. Bender, in a paper on "Wind Pressure," read before the Institution of Civil Engineers in 1882, says "cylinders have the special coefficient of 0.54, but larger surfaces probably increase this value." The author's investigations lead him to adopt $\frac{\pi}{4}$ — as the multiplier, which, if incorrect, is at any rate on the safe side. The area taken for wind pressure in the case of a circular chimney is the diametral vertical plane, and no further allowance need be made for suction on the lee side.

Pressure on Octagonal Chimney.—An octagonal chimney has two extreme positions with regard to the wind—viz., when it is acting directly against one face, and when acting directly against one edge. For the former case the author's multiplier would be 0.83, and for the latter 0.82; there is not much difference, but the latter coefficient gives rather the highest result as it is taken against the width over angles.

(To be Continued.)

THE ANNUAL MEETING OF THE CANADIAN SOCIETY OF CIVIL ENGINEERS.

The annual meeting of the Canadian Society of Civil Engineers is again a matter of history. This year the meeting, which was held in Montreal, was very well attended, and it can be seen from the report, which appeared in the daily issues of The Canadian Engineer and continued in this issue, that a good deal of interest was taken in the discussions.

It looks as if some change were necessary in the present method of carrying on the business of the annual meeting. The time of the meeting is all too short to allow of the discussion of reports of committees, etc. With the present mode of procedure, the first day and the morning of the third day are devoted to business and discussion of reports. The second day is the excursion day to the different plants to be inspected; and the afternoon of the third and last day is reserved for the meeting of the new council.

From the analysis of the discussion it appears that the general consensus of opinion is that the excursion day, or second day, should be devoted to business, and that the discussion of reports of committees be carried on at the meetings of the different branches of the society.

With the elimination of these two matters the business of the annual meeting would undoubtedly be much facilitated, and a great deal more time allowed to the actual affairs of the society.

The excursion is certainly a valuable function, for it aids greatly in the members getting acquainted with each other. However, by postponing it until the fourth day of the meeting it would serve this purpose nearly as well, and would give an additional day to the work of the society. The discussion of the reports of committees, in the opinion of many of the members, could be better carried on at the branch meetings. While there would undoubtedly be difficulties to this method of procedure, still these could be overcome if it were considered advisable to change.

The retiring president, Mr. C. H. Rust, suggested that an annual summer session would be an excellent thing, and the idea met with a great deal of approval. By this means many interesting places and works could be visited by the society as a body, which under present conditions are impossible, and it would afford an excellent opportunity for the members to become acquainted. The latter fact, after all, is one of the most valuable results of the society meetings.

THE LETHBRIDGE SEWAGE SEDIMENTATION TANK.

Patent rights have recently been granted in connection with a sewage sedimentation tank which introduces several novel features of construction. The working principle of the tank appears to be somewhat similar to the type known as the "Emscher," inasmuch as the object aimed at is the automatic immediate separation of sedimented solids into a separate section of the tank. The patented claim, however, only appears to cover the principle of separation or isolation of sludge in connection with rectangular tanks, and the constructive features may not be applicable to circular tanks as with the Emscher design.

Both forms of tank have been fully described and discussed in The Canadian Engineer and elsewhere, and it would appear that the principle involved in these modern types of sedimentation tanks, which is creating much interest in sanitary engineering circles, is likely to supersede the older types of efficiency.

Up to within a recent period we have been accustomed to hear so much about the efficiency of the septic tank that the name has almost become synonymous with the term "sewage disposal." In fact, in many quarters, when a municipality is contemplating the introduction of sewage disposal works, it is common to state that "septic tanks" are proposed without any definite knowledge of the particular form and method of sewage disposal under consideration.

More recently, however, we have been told that septic tanks are a mistake, that they have been founded on error and resulted in failure.

It now appears, however, that there are some good features connected with the much-maligned septic tank, and that it cannot be thrown altogether aside and scrapped. In fact, the newer forms of sedimentation tanks, which appear to meet the demand of modern conclusions and knowledge gained by experiment and practice, are simply a compromise between the old continuous-flow sedimentation tank and the septic tank. With the continuous-flow sedimentation tank the working principle depends upon reduced velocity of flow for the precipitation of the suspended solid matter and the immediate removal of the settled solids to sludge beds adjoining the tank, where they are generally allowed to rot and form the chief nuisance connected with any sewage disposal works. On the other hand, the principle of the septic tank is to allow the settled solids to remain in the sedimentation tank and undergo the rotting process, after which they can, at extended intervals, say, once or twice a year, be removed to sludge beds adjoining the tank without the same risk of nuisance, as the putrefactive process has taken place in the tanks, and the removed solids are practically of a mineral and non-offensive character.

The latter method gained much favor, and, under the term septic treatment, was very generally adopted as more economical and efficient than the daily removal of fresh sludge from tanks.

The method, however, very soon proved itself a partial failure as it was found very detrimental to the final treatment of the tank effluent to allow this sludge or settled solids to remain in the tanks in contact with the continuous flowing sewage.

The newer form of tank meets the above objectionable feature by providing a separate compartment, into which the solids are precipitated, where they undergo septic action or the putrefactive changes necessary to render them inoffensive on removal. At the same time the tank effluent is unaffected by the presence of accumulated putrefying solids.

Thus the efficiency which is peculiar to septic treatment of sewage is attained, together with the efficiency peculiar to the ordinary continuous-flow sedimentation tank. The Lethbridge tank also introduces several novel features, such as the use of wire reinforced glass for the tank slopes so as to accelerate the discharge of the settled solids into the separate decomposing chamber.

The Emscher tank is a German design, while the Lethbridge is Canadian, its name being taken from the city where it is being installed. We understand that this form of tank has been adopted at several other places in Canada.

EDITORIAL COMMENT.

The forestry question in Canada has become an exceedingly important one, and it is one which is of great interest to engineers, closely associated as they are with the building and constructional fields. Our forests have been depleted by fires and by the necessities of life until little remains of our original magnificent heritage. We must look to the future, and in doing so our only salvation is in scientific forestry. The Canadian Forestry Association are doing a great deal towards promoting a sane forestry programme, and the association deserves the support of all engineers. This association are holding their annual convention in Ottawa on February 7th and 8th, and the discussions at this meeting should be productive of much which will be of interest.

* * * *

We have drawn attention in The Canadian Engineer before to the fact that the executive of the Ontario Good Roads Association is completing arrangements for a provincial deputation to attend at Ottawa on Thursday, the 8th day of February. This deputation will wait upon Premier Borden and the members of his Cabinet to present their views in reference to federal aid for good roads and how it can best be distributed and applied throughout Canada, and Ontario in particular. An effort was made to bring this deputation together in December, but owing to the early adjournment of the House and other matters, a satisfactory date could not be secured. In response to the notices sent out in November, more than one-half of the county councils of the province expressed their approval of the idea by appointing delegates. A similar notice will go before the city, town and county councils this month, and it is hoped that all will arrange to be represented. A meeting for the organization of the deputation will be held in the council chamber of the city hall, Ottawa, on the morning of the day appointed, commencing at 9 o'clock.

LETTER TO THE EDITOR.

The Editor:

Sir,—I have read with interest the article by Mr. S. B. Code, O.L.S., concerning concrete sidewalks. This is a subject upon which very little is written; perhaps the idea is so simple, and there is not much to give to the engineering profession.

The suggestions put forward by the writer are well founded, but there are a few points which he touched upon in so general a way as to make the article of less value than it otherwise would have been. It would be interesting to know Mr. Code's opinion as to the proper thickness of the surface mixture, concrete body, and the foundation. I understand that some cities are laying cement walks at the present time, and do not provide any gravel or cinder foundation at all, and their walks have been reportd to be satisfactory. This, of course, is a matter which is governed by locality and condition of the foundation with respect to porousity or impermeability.

Another point is the distance between expansion joints, which are places in the neighborhood of 50 feet. It would seem to me that joints braced thus far apart is too much for ordinary severe climatic conditions, unless all the intermediate joints between each slab are perfect.

I would further remark, that as a general rule pitch between the expansion joints squeezes out during the

summer, and is very objectionable when the cold weather comes.

These points are matters which might well and profitably be discussed by members of the profession, and it would be interesting to get the ideas of various municipal engineers on the subject. Yours truly,

A. C. D. BLANCHARD, City Engineer.
Lethbridge, Alta.

THE CANADIAN HIGHWAYS IMPROVEMENT ACT.

The following is the text of the Act to encourage and assist the improvement of highways, which is now before the House of Commons at Ottawa. This is Bill No. 77 of the first session of the twelfth Parliament.

1. This Act may be cited as The Canada Highways Improvement Act.

2. In this Act the word "Minister" means the Minister of Railways and Canals.

3. The Governor-in-Council may, in any year, and upon such terms and subject to such conditions as are prescribed by order-in-council, grant to any province in aid of the improvement of existing highways or the construction of new highways in such province, or for both such purposes, a subsidy not exceeding such sum as may in such year be voted by Parliament for that purpose.

4. Any highway for which aid is granted to a province shall be improved or constructed, as the case may be, according to descriptions, conditions and specifications approved by the Governor-in-Council on the report of the Minister, and specified in each case in an agreement between the Minister and the Government of the province, which agreement the Minister, with the approval of the Governor-in-Council, is hereby empowered to make.

5. Each highway to be constructed or improved shall be defined and described in such agreement, and provision may be made therein for the future maintenance of such highway in good condition according to a specified standard and to the satisfaction of the Governor-in-Council.

6. The Minister, with the approval of the Governor-in-Council, and upon such terms and conditions as are prescribed by order-in-council, may undertake the construction of any new highway or the improvement of any existing highway in any province, and may expend in such improvement or construction the whole or any part of the sums voted by Parliament for such subsidy to that province. Provided, however, that the Minister shall first obtain the necessary authority from the legislature of such province and the consent of the Lieutenant-Governor-in-Council.

LECTURES FOR INSPECTORS.

The department of health of the city of Toronto have entered upon a series of lectures with a view to broadening and extending the usefulness of inspctors and others. The lectures are held once a week at 4.30 p.m., and all health inspectors are required to attend.

Among the subjects discussed are:—Bacteria, Their Nature and Functions; General Sanitary Inspection; Special Sanitary Investigations; Foods, Their Nature, Uses, Value, Adulteration, Preservation and Possible Dangers; General Food Inspection; The Milk Problem; House and Lodging House Inspection; Hygiene and Sanitation in the Home; Disease Carriers and the Value of Medical Inspection in Schools; Isolation Regulations and the Enforcing of Them; The Municipal Control of Tuberculosis; The Work of the Tuberculosis Nurse; Plumbing Inspection; Meat and Slaughter House Inspection; The Social Aspect of the Tuberculosis Problem; The Work of Charitable Societies in Their Relation to the Work of the Health Department.

An examination is held at the close of the series, when the results will materially effect the standing of inspectors and other employees.

REINFORCED CONCRETE—THE COLD WEATHER BUILDING MATERIAL.

In the winter many factory managers and mill agents are confronted with the fact that they must have an increased space to handle a larger factory production. Often this extension is deferred until the spring, as from bitter experience they are aware of the uncertainty of completion of mill constructed buildings due to the slow deliveries of materials and do not consider reinforced concrete either on account of its higher first cost or doubt as to the safety of construction under cold weather conditions. Buildings with steel frames are not considered, as very few factories are built of this design nowadays.

Very often factory managers will incline to mill construction on account of the lower first cost, while in ultimate cost, considering depreciation, insurance, interest, and vibration with its resultant wear on machines, reinforced concrete is cheaper in most every instance. In winter time concrete work will average from 6 to 10 per cent. more than the cost of work done in warm weather, and mill construction will cost from 4 to 8 per cent. more, but the early occupancy of the concrete building more than offsets the extra cost of concreting in winter, while with mill construction there is absolutely no surety of the completion of the building, four to six months being often taken to finish a building that should be put up in three months.

Reinforced concrete work that has been executed in the coldest weather is just as sound as summer work, provided proper precautions are taken. In New England, with its severe winters, for the last eighteen years a contracting firm in Boston, the Aberthaw Construction Company, have successfully carried through three or four jobs each year, under the most adverse weather conditions.

The principal points of winter concrete work consist in heating the sand, stone, and water before putting the same in the mixer. The cement is not heated, as its setting is hastened to too great a degree. Salt is sometimes mixed with the concrete in the proportion of two pounds of salt to each bag of cement. Of course all snow is removed from the forms by a steam jet, and the whole building as it goes up is enclosed floor by floor with canvas until the concrete is set and salamanders burning coke are placed underneath all freshly poured concrete floors and kept there until the concrete is thoroughly set. In this way the interior of the building is kept about 30 degrees above that of the air outside. The tops of the concrete floors which cannot be enclosed with canvas are covered with about 12 inches of hay or straw, the latter being sometimes sprinkled with salt.

On account of the speed and certainty of erection, together with its numberless known advantages, it seems that reinforced concrete construction in winter will become more and more adopted by factory owners, when it is realizd that with experienced contractors the soundness of the structure is just as good as if it had been erected in the summer time.

REPORT OF ANNUAL MEETING OF CANADIAN SOCIETY OF CIVIL ENGINEERS.

(Continued from daily issue of Jan. 26th.)

Friday Morning's Session—January 26th, 1912. PRESIDENT C. H. RUST in the chair.

THE PRESIDENT: If you will come to order, gentlemen, we will proceed with the business. The examiners of student papers have recommended to award the prize in the general section to Mr. Percy E. McDonald, for his paper on "A General Description of the Structural Detail of Buildings." We will now take up the reports of branches.

THE SECRETARY: The only outstanding branch is Vancouver, and I have not received a report from it.

THE PRESIDENT: We will proceed, then, with the discussion on the reports of committees.

THE SECRETARY: Before proceeding, I would like to call attention to the excursion that is provided for this afternoon for those interested to the Oxygen Plant at Maisonneuve, which is said to be exceedingly interesting, and Mr. R. J. Levy, the manager, has kindly undertaken to be here at 2.30 to conduct the party there.

Mr. Muckleston, of Calgary, sends a discussion on the report of the Committee on Roadbeds and Ballasting. I don't know whether it is in order to take it up until there is some member of the committee present.

THE PRESIDENT: Probably we had better leave it over for the moment. Is there any gentlemen here on the Committee for Roadbed and Ballasting?

MR. MACKENZIE: Mr. President, may I ask what you propose to do regarding this report?

THE PRESIDENT: Well, we want the report to be received, and if there is any discussion on it we will be glad to have it.

MR. MACKENZIE: Of course, I am not the chairman of that committee. I am simply a member of the committee and I am not authorized to present the report, but I have something to say regarding it, if it is in order.

THE PRESIDENT: Very well, it is now open for discussion.

MR. MACKENZIE: I think this is one of the most important reports that we have. I came here purposely to take a small part in the discussion of this report, and I may say that I am very much disapointed to find that the chairman of the committee is not present. I don't know whether or not there is any communication from him.

THE PRESIDENT: This matter came up the other day, and we postponed it until to-day. We have had no communication from the chairman of that committee.

THE SECRETARY: The practice has been to have any member of the committee who is present represent the committee.

MR. MACKENZIE: Since this is the case, is it in order that I should make a few remarks on this report before it it is received?

THE PRESIDENT: Certainly.

MR. MACKENZIE: I may say, then, Mr. President, that I heard nothing of this proposed specification until about a month before this meeting. I spent a couple of days going through it, and jotting down my views regarding certain points which are contained in it, which I sent to the chairman. The report, however, has been printed as it originally appeared, without any change whatever, and, as I said before, it is certainly a very important report, seeing that there is a great deal of railroad building being done in Canada at the present time, and I think it would be of very great benefit and convenience to all engineers engaged in railroad work that a standard specification should be adopted by this association. There are a great many different specifications in use at the present time on roadways, and this draft presented by the committee has been largely modeled on the standard accepted by the American Engineering Association, with improvements or supposed improvements sandwiched in here and there through it, producing what we have before us in this report.

Now, in comparing it with the standards as found in the 1911 Manual of the American Engineering Association, the first difference we find is in the marginal references. Here we have no marginal references at all. These are very convenient in actual work, and particularly if there is an index at the beginning of these marginal references. I think that these marginal references should be put on.

In paragraph 8, if you will kindly turn to it, it is stated:—

"Stumps shall be cut off even with the ground, where cleaning is to be done, except between the slope stakes of embankments, where they may be cut so that the depth of filling over them will not be less than 2½ beet."

Well, if that is carried out literally, you might have stumps there 17½ feet high. It seems to me that that requires revision.

Paragraph 11 says, "All trees that may be reserved shall be stripped of their tops and branches, made into ties, or cut to such lengths as may be directed and neatly piled up at such places on the right of way as may be designated, for which service payment may be made by the tie or by the cord of 128 cu. ft."

I think, Mr. President, with reference to that particular paragraph, that we should make it quite clear that the wood cut on the right of way belongs to the railroad company, and not to the contractor. These are little things, but they always come up in carrying out the work.

Now, if we are to make a specification as a standard, let us make it so clear that there will be no difference with the contractor when the work is being carried out.

In paragraph 12 it mentions that close cutting is to be included in the price paid for clearing. It seems to me that is not right. Close cutting should be paid for separately.

Paragraph 16 says: "Grubbing shall also be required between slope stakes of all embankments of less than 2½ feet in height."

In this paragraph the 2½ feet mentioned conflicts with the 4 feet mentioned in paragraph 18. That requires revision.

Paragraph 18 says that the payment for the grubbing shall be paid for separately. It seems to me it should be measured in square acres. The contractors understand square acres better than any other measure for that kind of thing.

The grubbing should be paid for as grubbing on excavation or anywhere else. It does not matter where the contractor does the grubbing, he ought to be paid for it. It is sometimes said that if a contractor takes out stumps with a steam shovel that he has no right to be paid for grubbing. That is not correct. It costs the contractors just as much to handle stumps with a steam shovel, as it does to grub them out anywhere else, because he has to handle them two or three times.

Am I going into too much detail, Mr. President?

THE PRESIDENT: We have a great deal of business to go through this morning, and I was going to suggest to you, that if the report is not satisfactory to you, Mr. Mackenzie, it should be referred back to the committee, because the committees themselves, before they present the reports, I understand, got together and agreed upon them.

MR. MACKENZIE: Well, it has not been agreed upon.

THE PRESIDENT: Well, had you not better move that it be not adopted but referred back to the committee again?

MR. MACKENZIE: Well, that would result in putting it a year back.

THE PRESIDENT: Well, as you are the only member of that committee present, it seems to me if we are going into it in detail, I do not know that we could do very much, because the other members of the committee may not look upon your ideas in the same way as you do, and it would be better if you are not satisfied with the report of the committee to have it sent back to the committee.

MR. MACKENZIE: These notes that I have been reading were sent to the chairman of the committee about three weeks before the meeting.

THE SECRETARY: Perhaps Mr. Mackenzie would give a general criticism with a motion that the report be referred back to the committee.

THE PRESIDENT: How would it do for you to make your suggestions in writing, which, of course, would make it necessary to have the report referred back for another year?

MR. MACKENZIE: I see nothing else than that. The report will have to be postponed for another year.

MR. MOUNTAIN: I quite sympathize with Mr. Mackenzie. I think we should have a finality to these things. (Hear, hear.) We are going on with these reports, and we all know that these reports are particularly useful to railway engineers, and we are now using—most of us who are railway men in this room—are using the American Railway Engineering Association standards. We prefer to use our own. This society has made standards and they are approved.

There is another one coming up shortly—the bridge specification. That committee was formed, I think, two years ago, and I understand to-day that it is to be brought up and carried over. Now, we are dealing to-day with half a dozen different specifications, and I for one would particularly like to see this matter closed up and some finality reached about these specifications.

THE PRESIDENT: How would it do, Mr. Mackenzie, to authorize this meeting to have these specifications adopted when they are revised, but not wait for another year.

MR. CLEMENT: The adoption of a standard specification by this society may debar certain members who are working under specifications of their own. I do not think the society should adopt the standard until all the members have had a chance to be present and discuss it. We have had brought before us a specification, and the only member of the committee present states that he took no part in that specification, and did not know it was being adopted by the committee. I would move, sir, that this report be referred back to the committee, and that it be brought before the various meetings of the sections and various branches for discussion, and that the result of these discussions be sent in in the form of suggestions to the committee for their consideration.

MR. DUGGAN: I entirely agree with the remarks of the last speaker. I think we ought to go further and revise our whole method of dealing with these reports. The matter was up in Winnipeg last winter and it was then agreed that the reports should be issued one month before the annual meeting, so that it might be discussed. As a matter of fact, we have at the annual meeting perhaps not over five per cent. of the whole membership of the society. There is a lot of other business to be attended to, and a report comes up. It is too long to be read over clause by clause, as it is in the other associations, and the thing is either adopted or rejected or sent back to the committee for continuance. I think that Mr. Clement's suggestion is an excellent one, that the report should be read by the various sections and got into shape and discussed by them, and I think we should go even further, and when a committee considers that a report has been discussed as far as possible, both before the various branches and by written communications, that they should issue a final report for letter ballot by the society. This society, stretched out as it is all over the country, can hardly deal with important matters in any other way than by letter ballot, and I do not think the time of this meeting can be taken up better than by passing a resolution to that effect. We should deal with these important reports coming up before us every year in a proper manner, and I have much pleasure in seconding Mr. Clement's motion.

THE SECRETARY: Might I say, for the information of those present, that as far as possible the resolution of the annual meeting at Winnipeg was carried out. The only reports which are presented here are those which were turned in a month before this meeting, and they were in the hands of the members—perhaps not a whole month—but about three weeks before the meeting. There are other committees who have not reported at all.

MR. MACKENZIE: There are just two suggestions that I wish to make before the discussion ends, with regard to the standard specifications. I intended to suggest that when this special specification is completed by the committee and before final adoption by the society as a standard, a copy should be sent to every member of the Canadian Society of Civil Engineers, giving him a month to reply, and to send in any suggestions or criticisms which he may wish to make by letter, to the secretary of the society. No one can then say he did not have a chance to say what he wanted to say about any standard specification, and further, I think it would be a helpful thing if a copy were sent to every one of our principal railway contractors in Canada, as some of these contractors have decided views with regard to these specifications, and I do not think it is quite fair that an engineer on one side and a contractor on the other side, who are associated in carrying out the work based on these specifications—I do not think it fair that the man who does the greater part of the work should have no say whatever in the specifications under which he is working. (Hear, hear.)

Some of these contractors are engineers as well as being contractors. Most of them are very intelligent men, and can give engineers pointers regarding the specifications, as well as the actual carrying out of the work every day in the week.

Now, I think we should have the secretary to ask the assistance of some of those contractors in preparing a standard specification which would be, I hope, a standard as long as we live.

THE PRESIDENT: Would it not be the proper thing for the members of the committee to send the information out to the contractors, and get their ideas before submitting a report?

MR. MACKENZIE: I think the society as a whole should, perhaps, request the committee to do that. It would carry more weight, and they might have very different opinions about the advisability of doing it. Some engineers know it all; the contractor takes what comes to him.

THE PRESIDENT: Of course the members of the committee would know better who the contractors are than probably the society at large.

MR. MACKENZIE: If the suggestion was made to them, I think it would be a great help to suggest that the committee do it.

THE PRESIDENT: Do you want to put your motion, Mr. Clement?

MR. CLEMENT: I do not know that my motion has been seconded.

MR. LEOFRED: It seems to me, Mr. President, that the Canadian Society of Civil Engineers should not overlook the remarks of the chief engineer of the Intercolonial Railway, who says to us very frankly that he has not been consulted, and that the committee, of which he is a member, never wrote to him stating what report they were going to propose for adoption. I believe, under the circumstances, we ought not to adopt this report without taking into consideration the very valuable remarks of the chief engineer of the Intercolonial Railway, whether in the form of a motion or otherwise. We should take his remarks into consideration.

THE PRESIDENT: Well, gentlemen, is it your pleasure that we dispose of this matter or leave it over for another year, by referring it back to the committee?

MR. DUGGAN: No, do not leave it over. It is too important.

MR. JAMIESON: This question of committees and the question of dealing with specifications is one that requires a great deal of consideration by this society. Now, if the society is going to issue specifications they should certainly be most carefully prepared and every point corrected before they are adopted by the society. That involves a very large amount of work by any committee, and that committee should have every consideration from the society, and should not be subjected to undue criticism, because there are many points that cannot be dealt with to the satisfaction of all; but one thing the committee should do, is to take care, I think, to have everything in as good condition as possible, and every clause carefully considered as widely as possible by the members of the committee as a whole after getting the advice of others wherever necessary. Then they should bring the report before the society and make their recommendations. After that the annual meeting may be able to deal with it to better advantage than we can in this way.

I understand it is quite impossible to discuss these reports clause by clause during our annual meeting, with the time we have at our disposal to do so, and unless we are going to devote the whole of the time to a discussion of the business affairs of the society, and cut out our trips around the city, and if these reports are not in such shape as to be above fair criticism, I think it might be well for it to be referred back to the committee for another year, with a view to getting them in that shape, and making final recommendations.

MR. MONSARRAT: Mr. President, I know in connection with the bridge specification, it has been very difficult indeed to get a discussion of the various clauses contained in it, on account of the committee being so widely separated all over the country, and, as Mr. Jamieson has said, there is a great field to be discussed and it takes a great deal of time. I think, therefore, it would help considerably if the committee would be furnished with a secretary who could look after the correspondence and the collating of information, and the resident members of the committee could discuss the matter and make suggestions. The secretary could see that these suggestions were forwarded to the outside members of the committee for their revision or suggestions and, after they had come to an agreement in the matter, then these reports could be submitted to the society as a whole, and written discussion sent in on them, or opportunities given to discuss them or bring up any point for the committee to discuss. Then the reports could be put in proper shape and submitted to the society at the annual meeting, which would thus eliminate a great deal of discussion at the annual meeting when there is very little time to do it properly.

MR. JAMIESON: I quite agree with the last speaker that when there are a number of committees dealing with these reports that there should be a secretary, who would act for all the committees, because it involves a great deal of research in connection with matters of specifications that the secretary could look up, and it is very difficult for the general members of the committee to get at it. The preparation of a specification is essentially a one-man job along with a secretary, and then it could be sent out to the other members of the committee for their revision or suggestions and concurrence after preparation, and then go through that final revision before being referred to the annual meeting.

THE PRESIDENT: At our annual meeting in Winnipeg we made provision for that, and we were given authority to spend money for that purpose.

MR. HARKOM: Instead of dealing with this special report, it seems to me that the discussion is taking a general form. As has been said here, I think it will be desirable to send out and get the expression of all the members before hand.

It seems to me that the act of putting out a specification by the society as authoritative and the society being responsible for a specification, should be very carefully considered. There is also the question as to whether the meeting, such as this annual meeting, is really properly qualified to dispose of such a subject. Would it not be better, Mr. President, that all committee reports, when they come in, should be dealt with by the Executive Council, and that they should not be issued as authoritative, but as recommended practice. Then again, it might be possible if that provision is made in that way, for a committee's report to be issued between annual meetings, and, if a secretary were appointed for that purpose, it could be sent out to all the members of the society who are interested and qualified to speak on the subject, and then the council might deal with it in a far more satisfactory manner than at a meeting like this.

MR. JAMIESON: Mr. President, pardon me if I again speak on the subject, but Mr. Harkom has raised a new point, and one that is very important; that is the question of sending in the report or specification for revision by the council. When we appoint committees at our annual meeting we are assumed to select for members of that committee those members of our society who are assumed to be best qualified to deal with the subject under discussion. If that is so, then that committee should be in a better shape to prepare their full report or make the specifications than the council is; and furthermore, they are appointed for that special purpose while the council has lots of other duties to perform. I think, therefore, it is essentially the work of the committee and not the work of the council.

It also raises the question as to whether those committees appointed at the annual meeting are committees of the whole society or committees of the annual meeting, or whether they are subservient to the council of the society—whether they should deal directly and report to the annual meeting or not. Of course all committees necessarily must work in concurrence with the council, because the council is the governing board of the society, but they should not be subservient to the society, nor have to depend on sending

in their report for revision to the council. Otherwise it would take away all sense of responsibility and pride that the members of that committee may have. I think we ought to know now exactly what is the standing of our committees.

THE SECRETARY: Mr. President, answering Mr. Jamieson, the procedure in regard to committees is quite definite, whether it is a proper one or not. It is this: The committees draw up their reports, when, in the opinion of the committees, the reports are ready they are sent in to the council, and the council is instructed by the annual meeting to send those reports out to the members for their information, and for any discussion they may wish to make. The reports are then supposed to be ready for consideration by the annual meeting.

MR. JAMIESON: Yes, but that does not involve the revision of any report by the council.

THE SECRETARY: No, certainly not.

MR. JAMIESON: I have raised this question because there are certain cases in which the council has, I think, stepped in where they have had no right to do so, and have interfered with the personnel of these committees. I do not wish to go into it any further, but it certainly is not right that it should be that way.

MR. HARKOM: It is not my intention to suggest that the Executive Council should be empowered with, or in any way to deal with, the report of the committees, confirmed by a ballot or referred to the society as a whole, but with the result that the committee's report should govern the council.

THE PRESIDENT: We are now discussing this report and nothing else, and I would like somebody to make a motion in regard to it, as to what we are going to do with this report on Roadbeds and Ballasting.

MR. JAMIESON: I move that the report of the Roadbed and Ballasting Committee be referred back to the committee for the incoming year, and I do this with a great deal of deference, because it is going to result in putting it over.

MR. SNYDER: I would move an amendment to the motion that the reports of committees, or every report, should be submitted to one special meeting of the society for discussion. It is utterly impossible to discuss so many reports at one single meeting, and if the reports on Bridge Specification are submitted at one meeting and nothing else, then we would have an interesting paper. It has been stated here that there are no interesting papers for discussion brought up in the society. These reports of committees are practically papers which are submitted to the society at the annual meeting, which could be submitted to one meeting and then they could be properly discussed, but I submit it is utterly impossible to do it properly at the annual meeting. Therefore, I move that the report of the committee be submitted to the society and be discussed at any meeting, but not at the annual meeting.

MR. DUGGAN: I understand, Mr. President, that you are dealing simply with this report of the Committee on Roadbed and Ballasting.

MR. JAMIESON: At the request of a member I add to my motion that it be referred back, and in the meantime, as early as possible, copies be sent out to all members for suggestions, and that as finally revised, be printed. If there is a demand for it, it may be issued in the meantime, of course, not as adopted by the society, but sent out for sug-suggestions.

MR. MACKENZIE: What I have asked Mr. Jamieson to include in his motion is, when the committee's report is made as good as they think they can make it, that they should send a copy to each member of the society and ask that member, within four weeks, to let them have the benefit of his suggestions or criticism, and that they should do that also in the case of prominent contractors who do such work.

MR. ST. GEORGE: Why not specialize the men to whom you would send it? For instance, a bridge report should be sent to bridge builders. It seems to me that would save a good deal of time.

MR. MACKENZIE: I mean to contractors in that particular line of work.

MR. HOLGATE: Is it not included in the Bulletin?

MR. JAMIESON: Well, that is the sense of the motion that I propose. I can write it out, if you like.

MR. McGOUN: I wish to second the motion.

MR. DUGGAN: I beg to move an amendment to the motion, adopting Mr. Clement's idea, namely, that this report be referred to the various branches, and that they be asked to discuss it, and report their discussion to the committee; and also, that every member should be asked by letter to send in their opinion or suggestions before the first of March, let us say, and that the committee should then deal with the suggestions and issue the report for letter ballot to the society.

If the matter is to represent practically a standard specification, it surely is a matter of sufficient importance to a lot of men who are at a distance to be given an opportunity to discuss it; it is merely a matter of dealing with the matter within the next two months in the same way as we would have to if it were referred back to the committee to be dealt with at the next annual meeting.

MR. CLEMENT: I second the amendment.

MR. JAMIESON: It seems to me there is very little difference between the amendment and the original motion.

THE SECRETARY: While the amendment is being prepared formally, there is a discussion from one member on this report. I have a communication from Mr. Muckleson, of Calgary, who sends in a discussion on the report of the Committee on Roadbed and Ballasting.

THE PRESIDENT: Had not that better be referred to the committee? Is that your pleasure?

Carried.

MR. SKAIFE: While the amendment is being prepared, there was a motion brought up the day before yesterday by Mr. Stead and it was duly seconded, and the meeting apparently took no notice whatever of it. I wish to bring that motion to the attention of the meeting now, and I would therefore move that in future the council form a reception committee to receive the outside members and see that they meet the local members of the society at every annual meeting.

THE PRESIDENT: I understood that Mr. Stead withdrew his motion at that time, and I stated that we would bring it up to-day as new business.

MR. JOHN KENNEDY: May I say just a word while the amendment is being prepared about these reports. I think it would be well if the Committee on Specifications would include in the specifications, as a specification only, those points upon which the engineers are pretty well agreed as a whole, and that the specification which may be considered as a standard specification, if adopted, should be accompanied by remarks upon recommended practice or variations under special conditions. In many instances variations are necessary for meeting special conditions, and remarks to that effect are very valuable.

I have in mind the specification of the American Society of Civil Engineers, and another of our own, which is all mixed up. The specifications proper and the remarks about what ought to be done in recommended practice, and what is done by the association for testing material in the United

States, are given, and there is an immense amount of valuable information in this, but it is utterly impossible to use it as a specification. One cannot refer to it and state that the work and materials are to be according to the specification of the Canadian Society of Civil Engineers, because it will not work as a specification, although it contains very much valuable matter. Now, if the specification proper were to include just such things as are standard and agreed upon for all ordinary occasions, and then be accompanied by an index with remarks upon recommended practice, or what is done under special conditions, it would be really more valuable and more easily workable. (Hear, hear.)

MR. DUGGAN: Mr. President, my amendment is as follows: That a notice be sent out requesting each of the branches to discuss this report and report the discussion to the secretary not later than the first of March. Also, that those who cannot attend the meeting be requested to send in written discussion before the first of March, and that the committee be requested to take such discussion into consideration and send out the report again for adoption by letter ballot not later than the first of June, such ballot to be returned not later than the first of July.

MR. SHERWOOD: Mr. Duggan's amendment seems to be in the right direction, but I think one important point is to get a discussion of the suggestions.

MR. TYE: It seems to me that the suggestion that these specifications and reports be discussed separately at a meeting, is a very valuable one. I think that personal discussion often brings out better points even than written discussion, and if this suggestion of Mr. Duggan's could be carried out and then referred to one of our ordinary meetings called for that purpose, it would be then discussed just as an ordinary paper would be, and I think you would get good information from discussion in such a way. (Hear, hear.)

MR. MACKENZIE: I see that the amendment has ignored the suggestion that prominent contractors in the same line of work should be given an opportunity to make suggestions or criticisms. If it is the sense of the meeting that that should be, I have nothing further to add. Otherwise I think it should be included in the amendment.

MR. DUGGAN: I did not intend to ignore that suggestion by any means. I think Mr. Mackenzie's suggestion is an excellent one. I should think the committee, in dealing with the specifications, would be only too glad to get ideas from contractors, and I would therefore amend my amendment that notice be sent out to members of the society as well as to the prominent contractors. Of course, it is a difficult thing to include it in the motion.

THE PRESIDENT: The resolution and the amendment are practically the same, with the exception of the word "contractor."

MR. TYE: I wish to put that suggestion of mine in the form of an amendment to the amendment, or perhaps Mr. Duggan, who seems to favor it, might include it in his amendment and not necessitate a further amendment being made.

MR. JAMIESON. Is it not in order for the society to call a meeting and have it discussed?

THE PRESIDENT: When?

MR. JAMIESON: Right away, or at any time.

THE PRESIDENT: Yes, I should think so.

MR. JAMIESON: I mean without a motion to that effect.

THE PRESIDENT: While the amendment is being prepared with the further suggestions that have been added, there is a resolution that has been moved by Mr. Skaife to the effect that hereafter at all annual meetings of this society a reception committee be named by the Executive Council who shall see that the outside members meet the local members. This is moved by Mr. Skaife and seconded by Mr. Harkom. What is your pleasure, gentlemen?

Carried.

MR. DUGGAN: My amendment will now read as follows: That notice be sent out requesting each branch to discuss this report and report the discussion to the secretary not later than the first of March. Also, that those who cannot attend the meeting be requested to send in a written discussion before the first of March. That the committee be requested to take such discussion into consideration and ask for a letter ballot on a final draft of the report, not later than the first of June, such ballot to be returned not later than the first of July.

THE PRESIDENT: You have heard Mr. Duggan s amendment, which has been seconded by Mr. Clement. What is your pleasure?

MR. JOHN KENNEDY: Does this amendment refer to all reports or to this special report?

THE PRESIDENT: To all reports.

Carried.

THE SECRETARY: Might I ask what would happen after the first of July?

MR. DUGGAN: The council will issue it.

MR. McGOUN: I think that all the members here present should have an opportunity of discussing this now.

THE PRESIDENT: Well, I have declared the amendment carried.

MR. McGOUN: The report of the annual meeting asks for discussion of all reports, and it seems now that all this discussion is cut out. We who have come here from a distance do not get an opportunity to discuss it.

MR. DUGGAN: I might say that I had no intention of cutting off discussion in making my amendment.

THE PRESIDENT: There is another important matter for discussion, and that is the proposal to sell our property. I will ask the secretary to read the communications that he has with regard to this project.

MR. SKAIFE: I would like to ask in this connection if there is a real estate broker's commission of two and a half per cent. to come out of the amount mentioned, or do we deal directly with the purchaser?

THE PRESIDENT: We do not pay any commission.

MR. TYE: I will be glad to move the necessary resolution. As I understand it, it is the case of a railway taking the property, and they can expropriate it if they see fit. It seems to me that this offer which we have obtained is a very good one, and we are not likely to get anything better.

MR. MARCEAU: I second the motion.

MR. OGILVY: As a matter of information, Mr. President, will you state what this property stands on the books of the society at the present time?

THE SECRETARY: A little less than $16,000.

MR. KEEFER: When do we require to vacate the premises?

THE SECRETARY: Theoretically on the 1st of May, but practically not for some time.

MR. KEEFER: Has the committee any other site in view that we can obtain?

THE PRESIDENT: Yes, we have two or three sites in view.

MR. KEEFER: Have you figured out how much it comes to by the square foot?

THE SECRETARY: It comes to a little over $20 a foot.

MR. ST. GEORGE: Is there interest to be paid on the other two instalments of ten thousand dollars?

THE SECRETARY: Yes, at six per cent.

MR. MURDOCK: Will it cost more or less than $60,000 to get the new premises.

MR. TYE: I think we should take this occasion to get a better site and a better house than we have now. This is getting a little small for us, and I think we could very well afford to take the $60,000 and put $20,000 or $30,000 more to it, and get a good place.

THE PRESIDENT: What is your pleasure, gentlemen, shall we approve of this sale?

Carried unanimously.

MR. SKAIFE: I would like to move in connection with this matter of securing new premises, that a building committee be named by the society for looking after the erection and procuring of a site. I think the council of the society has enough to do without looking after that matter exclusively, and I would like to name Mr. St. George on that committee. I cannot help remembering the services he did in connection with securing this site and building.

MR. ST. GEORGE: No, no; leave it to the council.

THE PRESIDENT: I think that had better be left to council.

MR. SKAIFE: All right.

MR. ST. GEORGE: It seems to me the council should be authorized by this meeting, if it is necessary, to purchase another property without coming back to the society for authorization, but I think we should give them authority now to make the purchase of a site which is satisfactory to the council, without coming back to the annual meeting. They have to do it, and there is no use calling upon the society again. I think we have confidence in the council, and that that matter should be left entirely in their hands.

MR. SKAIFE: I wish to second the motion.

MR. ST. GEORGE: I would add to my motion that the council be given such powers to spend the necessary money to erect a suitable building—a building that will be a credit to the society, even if we have to go in debt, because we could afford to go in debt, but my suggestion is that we should have something good, and something that will be a credit to the society. (Hear, hear.)

MR. TYE: Well, would it be necessary for the society to say how much money the council might spend in connection with this proposal?

MR. ST. GEORGE: Well, let us say not to exceed $100,000.

THE PRESIDENT: What is your pleasure, gentlemen, in connection with this motion?

Carried unanimously amidst applause.

PROFESSOR HAULTAIN: With all due deference to the mover and seconder of this motion, it seems to me you are passing a very serious matter, very casually. I repeat this statement as a non-resident of Montreal. I think that we outsiders who are not represented here should have something to say as to whether $100,000 should be spent on a building in Montreal.

THE PRESIDENT: The matter is not open for further discussion. The next order of business is the report on Railway Ties.

MR. TYE: Why not apply to this report the same procedure that we applied to the last report, and then we would not require any discussion here at all.

THE PRESIDENT: What is your pleasure, gentlemen?

Carried.

MR. MOUNTAIN: What about the bridge report?

VOICES: The same thing.

THE PRESIDENT: Is it your pleasure that Mr. Duggan's amendment apply to all reports of the different committees?

MR. DUGGAN: I must say that I made my amendment simply to deal with the report that was then before the meeting. I think it is a great mistake when men have come a long distance to discuss these matters that they should not have an opportunity to do so. If we have other business of importance to get through, let us dispose of it, and then we can go on and discuss the reports as long as we have time to do so; that is to say, let us resolve ourselves into a committee of the whole society to discuss these reports, because I do not think they should be disposed of in any such offhand manner as is now suggested.

MR. JAMIESON: I agree with Mr. Duggan that if the society is going to issue specifications there is scarcely any more important business that we have to deal with in order that they should be put out in proper shape, otherwise we should not put them out at all.

THE PRESIDENT: I quite agree with you.

MR. TYE: Well, don't you think that this method of dealing with them is going to reach that result? We have only an hour or so more to discuss these things and we cannot go through all these reports in that time. They are going to be discussed at the annual meeting; the only thing is to do the same as the Maintenance Society in Chicago does. If they are going to be taken up at the annual meeting, there is nothing else to do but cut out all our visiting, and if we are going to have these strictly business meetings, we will have to discuss the reports and nothing else, and give one-half the day to general business only, but it seems to me this other way of having the reports discussed by the different branches and finally sending out a letter ballot is a very good way, in view of the fact that we do like to take these excursions to the different places of interest in the city.

THE PRESIDENT: If we get through our business in time we can have some discussion on these reports. What is your pleasure regarding the motion?

Carried.

THE PRESIDENT: We have the report of the scrutineers and the Nominating Committee and several other matters now before the meeting.

MR. CHIPMAN: What is the first on the program?

THE PRESIDENT: We have now disposed of all the reports, Roadbed and Ballasting, Railroad Ties, Good-Roads, Sewage Disposal, etc.

MR. CHIPMAN: I was not aware that the sewage report had been disposed of.

THE PRESIDENT: Well, it was not quite settled, but I understand all these reports are being sent back to the committee.

MR. CHIPMAN: Until next year?

THE PRESIDENT: No, certainly not.

MR. JOHN KENNEDY: There is one question in connection with the sewage disposal matter that I would like to bring before the attention of the meeting, and that is, that the Senate of Canada has a bill on sewage disposal—a rather drastic one—and it will come before the House shortly, and the point is whether this society should take any part in that matter in any way, either official or unofficial, or through a committee, or in any other way. If our opinion is of any use at all, it is time to put it in. I confess to being somewhat puzzled along just what lines we should act. If we can do anything towards assisting the Senate, it seems to me it should be done at the present time. There is some danger of a law being passed which will be unworkably severe.

MR. MACKENZIE: What are we going to do with the Good Roads report? That was a very important report. We don't know that there are any imperfections in that report, or anything that requires revision.

(To be continued.)

BITUMINOUS ROADS.*

By Major W. W. Crosby.

It is not the purpose of the speaker to trace the history of bituminous road work from the early efforts of the Peruvians, nor even to review the work of this country for the past 40 years, but rather to touch merely on some of the points in it at present of so much common interest and, in so doing, perhaps to suggest a thought or two that may be of value in stimulating consideration and discussion of this important subject.

For surfacing roads—usually called "Streets"—in cities, the larger practice in the use of bitumen has been to use it in the form of asphaltic cement, such as in sheets or block asphalt pavements. Such pavements, under proper conditions, give good satisfaction at reasonable expense. The first cost of them varies between $1.50 and $3.50 per sq. yd., however, and in recent years an effort has been made to secure a similar surface, of even wider applicability, at reduced cost. Incidentally, success in this line would offer a much needed surfacing for filling the gap between the best macadam, cheap but sometimes of questionable satisfaction, and the rather expensive asphalt pavements referred to.

In this effort, the use of cheaper bitumens—such as the tars for instance—has been tried, and also new methods and mineral materials for the body of the pavement, cheaper than the graded hot sand required for the sheet asphalt. Much success has been had with naturally some failures. This work, as a whole, however, in the cities has been so like the development of the country roads along the same lines, and the distinction between a highly developed country road and a minor street in a city is so lacking in clearness that we probably may proceed, with this reference to city work, to the consideration of road work proper.

Bituminous roads constitute a modern development to meet both the actual needs under modern traffic and the desires of modern civilization for greater efficiency, comfort, satisfaction and better sanitary conditions. The advent of the motor vehicle has greatly changed the conditions under which a road existed. Good roads are in greater demand owing to the greater radius of action of the automobile. Smoother roads are more desired because of its sensitiveness —at its greater speeds—to slight inequalities of road surface. More cementitious surfaces are needed, due to its ability to destroy the bond of the stone surface, to cause internal friction and wear of the pieces of stone forming the crust, and to render the road thus more susceptible to the elements. And further, the dust, which formerly laid on a good road surface and which, when not too profuse, was not only not seriously objected to, but was of some actual value in the protection which it afforded the stones composing the road, has been violently brought to our attention by the motor—so violently and powerfully in fact that we are now well aware that, under recent conditions at least, the disadvantages, discomforts and unhealthfulness of this dust far outweigh any good it may formerly have possessed.

None of us believe that the remedy for this state of affairs is the abolition of the motor-vehicle. Most of us who do not possess one are looking forward to the day when we may, and most of those who already are fortunate enough to own one are anticipating the possession of two or of more.

So the remedy seems to be to cure the defects of the road. And the speaker wishes to here again repeat what he has frequently said before, i.e., there is no one "best way" nor one "best material." The decision as to method or material to be used must depend in each case upon conditions of traffic, availability of different materials, desires of locality, and probable changes of conditions during the life of the work decided on to be done. A clear recognition of this fact is important for good work and economy. It is somewhat surprising how often it appears to be overlooked even among those who would be expected to appreciate it most.

Let us suppose now that we have the improvement of a certain road contemplated and that the details have all been worked out except as regards the road surface itself: that there is no question but that as soon as the road improvement is completed, a considerable number of motor-vehicles will use the road daily, say, not less than 20 every 24 hours. Then there is no question but that the road should be treated with bitumen either during or immediately after the construction of the surface with gravel, shells or broken stone, if economical and satisfactory maintenance is to be had. The treatment may also be justified for other reasons.

There may be said to be three ways in which a road surface may be treated with bitumens. These are, The mixing method; the penetration method; the method of surface applications, after construction in the ordinary manner.

A choice of these methods depends, as before stated, upon conditions. Such choice may be largely affected by traffic conditions but it is not yet clearly established just what amount of traffic demand justifies a selection of one method from the others. We are acquiring information on this point and it is hoped it may soon be clearer.

Generally, however, the choice is largely affected by other considerations, such as of comfort, health and satisfaction to the users or abutters, and the speaker believes that in making the choice it is well to be on the safe side from all these viewpoints. It is almost inevitable that, once a road is well improved, the previous traffic records will become almost worthless except for historical purposes. Consequently he believes that apparent extravagance in the choice at first may often prove later to have been true economy.

Although the speaker referred to construction alone in the foregoing, the remarks apply equally well to reconstruction or to repairs to a road that has deteriorated beyond the point where a surface treatment can be safely expected to relieve the needs.

At this point the speaker must inject the remark that it is his opinion that reconstruction is often attempted when a thorough surface treatment is all that is needed—not true economy. He is convinced that in the near future the use of proper surface treatments will be far wider and of greater satisfaction than it has been up to the present.

Now, the Mixing Method, as the term is generally understood, consists of mixing with the mineral material composing the wearing course of the road a sufficient amount of bituminous cement. This mixing is usually done at a plant off the roadway itself and even perhaps some distance from the site of the work. The materials may be mixed either heated or at the normal temperatures of either or both according to the method and materials employed, and by hand or by machinery for the purpose as desired. The mixed material is then taken to its place, spread and rolled and then frequently given a flush coat of bitumen and grit and again rolled. Satisfactory results from this method cost from 30 cts. to $1.50 per sq. yd. over and above what would have been the cost of an ordinary modern water bound road under the same conditions. The advantages claimed for the mixing method include great uniformity of surface and of composition of same, maximum value of surface for materials used, economy in use of materials, maximum life of surface and economy of results. There seems to be no question but that the mixing method has proved capable of producing high class results. There is grave doubt if it has always

* Paper read before the American Association for Highway Improvement, Richmond, Va., November 21, 1911.

been the economical method to have followed, and there are many instances of its utter failure. The mixing method frequently involves a considerable investment for machinery and with its first cost has led to the development of the Penetration Method.

In brief, the Penetration Method consists of simply applying a coat of pitch to the wearing course of the road just before the binding of this course by dusting, watering and rolling as usually practised in modern water-bound work. The pitch may be applied cold if properly prepared, though it is usually used hot. After its application, the pitch is coated with grit and the road thoroughly rolled. The cost of the Penetration Method varies between 10 cts. and 50 cts. per sq. yd. above the cost of water-bound work under the same conditions, according to methods, materials and quantities of the latter used. The advantages claimed by its advocates include sufficient uniformity of surface, economy in first cost, economy in long run, simplicity of operation and avoidance of complicated and expensive machinery, not to mention freedom from interference by patent infringement claims.

There is no doubt but that high class results can be secured by the penetration method. There are plenty of records of failure, however.

The method of Surface Treatments is only applicable to road surfaces already finished under other methods, usually to old or new water-bound work. In brief, the method consists of cleaning the old surface to be treated so that it shall be free from all fine material and refuse, even to washing it with water if this be necessary. After such cleaning, and when dry and as warm as practicable, the pitch is applied, allowed to soak into the surface for a longer or shorter time, as the material used may demand, then covered with grit and rolled. The process of applying pitch and chips may be repeated immediately, or after an interval as may be necessary. Sometimes two or more applications of pitch and chips are necessary for satisfactory results, and the interval between applications may vary from a day or so to a year or more, depending on local conditions. The pitch may be spread by hand or machinery as convenient, and either cold or hot, as its character may permit.

The cost of Surface Treatments varies from 5 cts. to 20 cts. per sq. yd. The advantages claimed for this method include simplicity of work, economy of first cost and, in many cases, economy in long run, lack of serious interruption to use of the coal, ease of repairs and renewal. Unquestionably satisfactory results have been secured under the method of surface treatments, and the speaker believes this method offers an easy and economical way for the revivifying of a road about to otherwise need resurfacing at a far greater cost under old water-bound methods or under either of the other two methods of employing bitumen.

The earlier success of the Mixing Method and the consequent attracting of attention to this method led many road workers to rush into it, believing it to be a panacea for all the road ills they were familiar with. A little later its extravagance in many cases became apparent and the Penetration Method received some followers. Still later the unnecessary expense of even this method became apparent for many cases and the method of Surface Treatments developed. Unquestionably, each method has its uses and the proper selection of one for a particular case is the end to be aimed at. The sphere of action of each is merged with or overlapped by those of the others and it will be some time yet before they can be clearly separated. The method of Surface Treatments is particularly applicable to use on old roads, and as water-bound construction will predominate for the near future at least, so will Surface Treatments grow in use.

The speaker is unable to wholly agree with a statement that had been made elsewhere to the effect that "the water-bound road is a thing of the past." He is yearly building a hundred or more miles of water-bound road and looks for such work to be continued indefinitely, as there are many localities where dustiness is less objectionable than increased first cost. But as these water-bound roads develop traffic over them, and as their extent and age increases, there comes a time when treatment is demanded and then Surface Treatment with pitch is often most advantageous and satisfactory.

In each of the methods referred to, a variety of materials may be used. At the present time, except possibly in the case of certain asphalt used for pavement work, the critical characteristics of a bituminous material to insure its being satisfactory in use under any definite method or conditions are not settled. Gradually, experience with them is clearing up the problem, but it is likely to be some time yet, owing to the variety already available and new forms yearly coming out, before definite knowledge will be had. Such knowledge will, of course, be hastened by co-operative effort, such as this meeting, and careful co-ordinated records of work done, which records are already being collected by the Committee of the American Society of Civil Engineers. About all that can be said now is that certain materials will generally give good results; many materials will be satisfactory when properly used; some are extremely limited in their application; and some are practically worthless.

In the foregoing we have perhaps dealt mainly with the use of bitumens or pitches in connection with ordinary road materials. And it may seem that it all was toward the end of improving what would, in many cases, have been a fair road, or under earlier conditions have been an excellent road. There is, however, another large consideration for the wider use of bituminous materials in road work. By such use many materials otherwise unfit for road surfaces—such, for instance, as the harder sandstones, granites, flints, etc., without binding powers—can be most satisfactorily availed of a great bridge over the Shimonoseki Straits for railway bituminous materials, soft stone, oyster shells, marl and even sand, can be made to cheaply form a road surface that is both highly satisfactory and most economical in a great many instances. And again, by the use of a relatively light and cheap "carpeting" of pitch and stone chips on its surface, the speaker believes many, if not all, of the defects of concrete for a road surface will be overcome. If so, a large avenue is opened for progress toward satisfaction and economy.

The selection of proper methods and materials to fit the conditions is the particular province of the unbiased and competent expert, and should not be attempted by the inexperienced nor entrusted to an ignorant or prejudiced party unless failure in some feature of the work is to be expected.

The speaker wishes to briefly suggest two thoughts more:

The first cost of bituminous roads is not a correct basis for the proper comparison of either materials or methods. Desirable, even satisfactory as such roads may be, they, like all other roads, require also maintenance.

This maintenance means expense even though reduced from the earlier figures for such work. And such maintenance should be, with bituminous roads as well as with any others, prompt, sufficient and efficient.

A LARGE BRIDGE.

A Japanese bridge project contemplates the construction of a great bridge over the Shimonoseki Straits for railway and highway purposes, to replace ferry connection. The bridge would be at an elevation of about 165 feet above water, and its total length would be over 3,700 feet.

LETHBRIDGE SEWAGE DISPOSAL WORKS.

The following description of some of the main features of the Lethbridge sewage disposal works, now under construction, should be not only of Canadian but also of general interest. The design of the sedimentation tank is understood to be original, and possesses certain features which are intended to obviate the recognized objections to the ordinary septic tank form of construction.

Generally speaking, the works are designed in order to obtain a reduced character of sewage effluent amenable to disinfection at the lowest form of construction.

The city of Lethbridge is situated in southern Alberta, on the banks of the Belly River, a stream of considerable volume, which joins the South Saskatchewan River. The city obtains its water supply from the river, which also serves as a water supply for several large coal mining centres located below Lethbridge. The population is over 12,000, and the normal water consumption converted into sewage about 700,000 gallons per day. The city is sewered on the separate system, but a proportion of the rain fall enters the sewers from roofs and a small amount of subsoil water also enters the sewers.

There is one main outfall sewer for the whole system, which up to the present has discharged raw sewage into the Belly River about a quarter of a mile below the city intake.

The demand for sewage purification is caused by the large number of typhoid cases in the mining centres depending upon the river as a source of water supply below the point of sewage discharge.

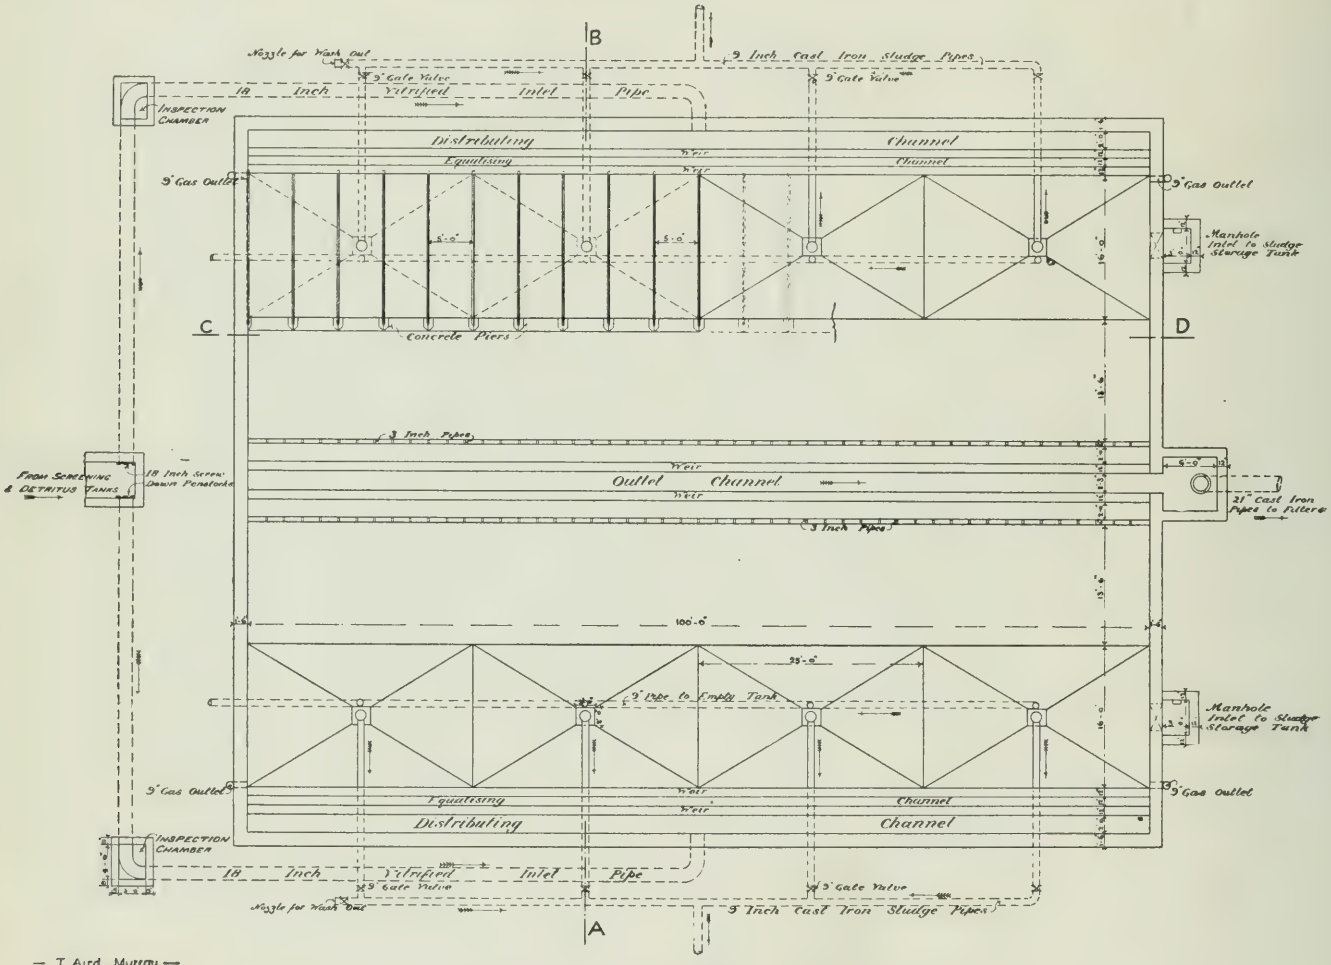
The discharge of sewage varies considerably at different periods of the day, and is only slightly affected by rainfall. Weir readings at the outfall sewer led to the conclusion that the proposed works be constructed to deal with and show a maximum rate of discharge of 2,000,000 gallons per day, a normal rate discharge of 1,000,000 gallons between 6 a.m. and 9 a.m., with a minimum rate discharge of 400,000 gallons per day between 9 p.m. and 6 a.m. Several of the water mains are composed of wood stave pipes, and much of the night flow is considered to be due to direct leakage from the mains to the sewers.

A series of analyses of samples of the sewage show it to be comparatively fresh at the point of discharge, the gradients being excellent and the distance of flow short. The average strength of the sewage is comparable with the class as described as weak in the fifth report of the Royal Commission on Sewage Disposal (Great Britain.)

Fortunately there is sufficient natural fall to allow of the sewage being treated before it enters the river without pumping.

Fig. 4 shows the general layout of the scheme, consisting of, 1st, detritus and screening tanks; 2nd, continuous flow sedimentation tanks; 3rd, percolating filters; 4th, humus tanks; 5th, chlorine mixing chamber.

The 1st, 2nd, 3rd and 4th stages of treatment may be said to be entirely subsidiary to the 5th stage, viz., that of disinfection. The preliminary methods are employed in order to ensure an effluent which can be disinfected at a high efficiency with a low annual cost. Experiments with refer-



—PLAN—

Fig. 1.

ence to the disinfection of the sewage tended to show: 1st, the difficulty of obtaining satisfactory disinfection without the removal of a large proportion of the solids; 2nd. That, in order to disinfect the settled sewage liquor after 70 per cent. of the suspended solids were removed there was required approximately 10 parts of chlorine per 1,000,000 parts of the sewage liquor; 3rd. That in order to disinfect the sewage liquor after it had been well oxidised and rendered chemically stable, it required approximately 3 parts of chlorine per 1,000,000; 4th. That, after oxidized liquor had stood for 1 hour for further sedimentation, that from 1½ to 2 parts of chlorine were required in order to obtain satisfactory disinfection. The above experiments were carried out with only small quantities of sewage and under circumstances which only allowed of very general conclusions. The general conclusions were so far in agreement with other experimental work of E. B. Phelps and others that they reasonably appeared to justify as follows:—

Supposing 2,500,000 gallons of sewage per day. To disinfect the liquor, after 75 per cent. of the solids have been removed, at ten parts of chlorine per 1,000,000 of sewage liquor, with chloride of lime at 1.5 cents per pound, the cost would be $4,000 per annum for lime only. To disinfect this sewage after thorough oxidation in filters and the removal of the filtrate humus, at 2 parts of chlorine to 1,000,000 of effluent, the cost would be $800 per annum. The difference in annual cost capitalized at 5 per cent. represents $64,000. Filters for oxidizing sewage at 2,500,000 gallons per acre at 6 feet 4 inches in depth can be constructed in Canada at a cost of $30,000 or $3 per cubic yard of filter material. There is thus a capital saving of $34,000 by adopting oxidizing filters rather than attempting to disinfect a putrescible effluent, on a unit of 2,500,000 gallon, sewage discharge.

The point where the capitalized cost would be warranted of disinfecting a putrescible sewage liquor rather than providing a non putrescible liquor by filtration followed by disinfection appears to be when only about 4 parts of chlorine are required for disinfection. The writer is strongly convinced that owing to the difficulty of penetrating even the finer solids and treating unstable sewage liquors with chlorine; that it will generally be found expedient to adopt what may be termed the standard methods of sewage disposal in order to obtain non putrescibility before disinfection is attempted.

Stress is laid upon the above point, for the reason that the proportion of dilution of volume of minimum flow in the Belly River to the sewage discharge, is away beyond that which is considered necessary to ensure oxidation by dilution.

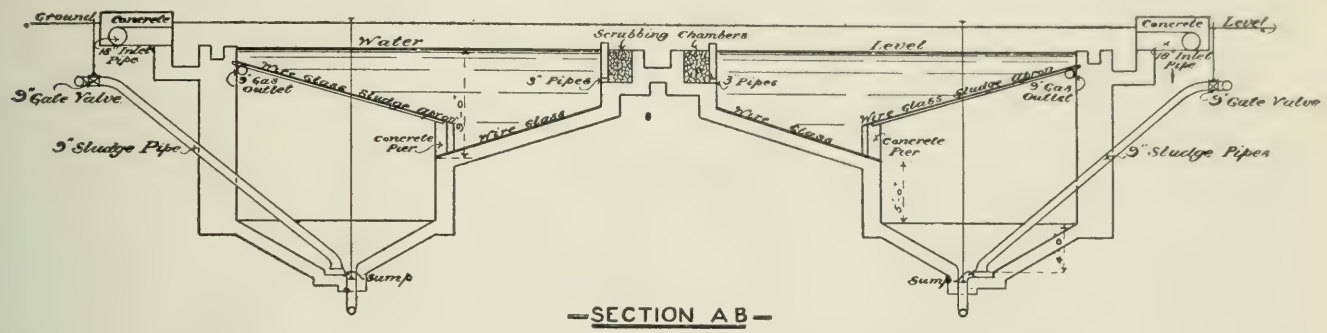


Fig. 2.

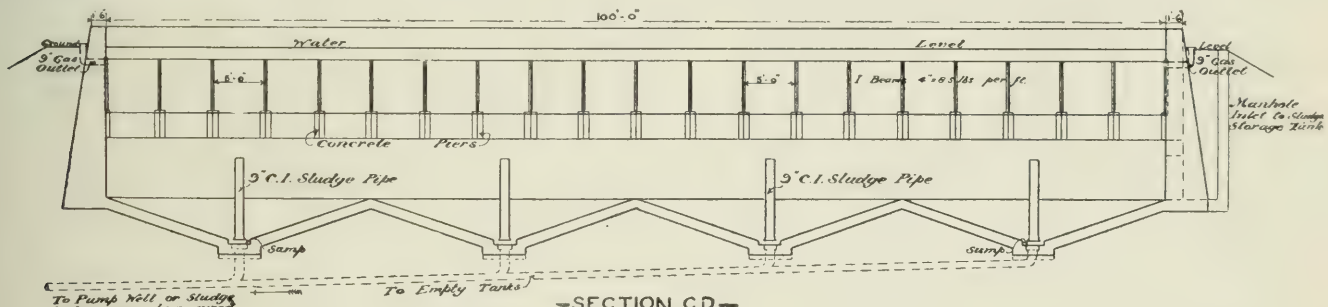
—T. Aird Murray—

Detritus Tanks.—These are built in duplicate, each 15'.0" x 8'.0" with a depth of 6'.6", with a total capacity of 10,000 gallons, providing a normal velocity flow of 1.7 feet per minute. Wrought iron upright screens are fitted across the tanks with ½ inch openings between the bars.

Sedimentation Tanks.—Are in duplicate as per figures, 1, 2, and 3. It will be noted that the sewage is delivered over a weir the full length of the longitudinal side of the tank. This is in order to obtain a low velocity of flow with as short a period of contact as is practicable, and is a departure from the ordinary custom in septic tanks of discharging the sewage over a weir the width of the cross section only and providing a considerable length of passage for the supernatent liquid over the settled matters. The settled sewage leaves the tanks by means of 3 inch pipes fixed below the sewage level and set at equal distances apart along the whole longitudinal length of the outlet and wall, thus ensuring that no floating matters pass off with the settled liquor. The settled liquor passes up and through scrubbing chambers of clinker before it enters the main outlet channel to the filters.

Each tank is practically divided into two compartments, as in the case with the Emscher Tank. A reinforced wired glass apron is made to project into the tank the whole



—T. Aird Murray—

Fig. 3.

longitudinal width. This apron covers what is called a sludge storage basin or area, and has a slope of about 1 in 5. The fore basin of the tank is also lined with glass with a similar steep slope. The apron overlaps the fore base and rests upon piers which are set intermittently allowing of openings between the sludge storage basin and the main body of the tank.

The working principle aimed at is, that, by means of the low velocity of flow owing to the wide cross sectional area of tank, precipitation of the solids will take place upon the apron and the fore base and that owing to the steep slopes and the minimum of friction presented by the glass surface, the precipitated solids will continually be delivered into the storage area or basin. In this basin putrefactive decomposition may be allowed to take place, with the result that such action will be entirely separate from the flowing supernatent fresh sewage The gases arising from decomposition will rise and impinge upon the lower surface of the apron and will be carried off by vent pipes to the outside of the tank, as shown. The many advantages of a decomposed sludge will thus be obtained without the admitted disadvantages resulting from sludge decomposition in contact with fresh flowing sewage.

Several of the above types of tanks are being constructed under the writer's direction in Canada and one installa-

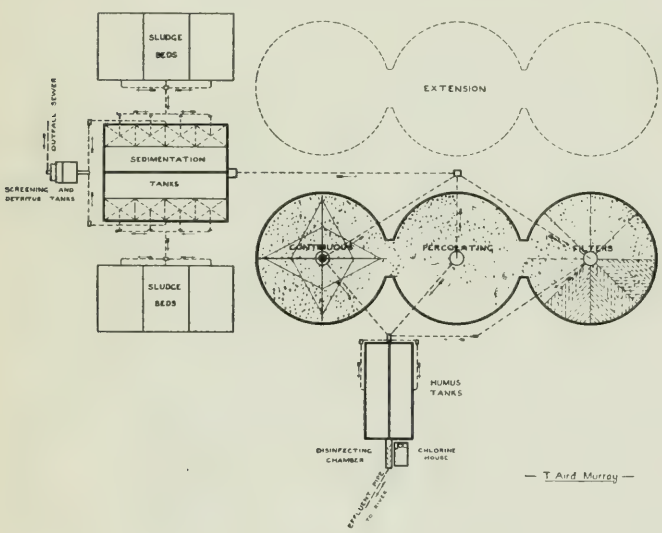


Fig. 4.

tion has been in use for some time, and although apparently giving excellent results, has not yet been in operation long enough in order to provide opportunity to obtain official and reliable data. The type of tank although similar to the Emscher as far as the objects aimed are concerned was designed before the Emscher was known in Canada, and no data as to comparative efficiencies as yet exist. The Lethbridge tank, however, is not costly as far as construction is concerned, and the principle of the glass apron appears eminently suited to a retangular form of tank for covering a sludge storage basin separated from the main body of the tank.

The sludge storage capacity in each tank up to the level of the lip of the forebase is equal to 60,000 gallons, while the sedimentation capacity is equal to 100,000 gallons. The velocity of flow through the tank is at the rate of .002 feet per second at the normal rate of flow of 1,000,000 gallons per day, and twice that velociy at the maximum rate of flow.

Filters.—The settled liquors from the above tanks is distributed over circular percolating filter beds, there being three in number each 108 feet diameter, with a depth of 7 feet of clinker graded from 2 to 3 inch cubes. The rate of filtration at the normal flow is 140 gallons of sewage per cubic yard of filter material.

The distributing apparatus consists of revolving distributors actuated by 2'.0" head difference between the level of the sewage in the tank and the level of the filter material in the beds. The distributing apparatus and other special mechanical appliances are designed and supplied by Messrs. Adams & Co., hydraulic engineers of England. The sub drainage of the filters is conveyed to the centre of each bed and from thence to humus sedimentation tanks.

Humus Tanks.—These are in duplicate each 80'.0" x 15'.0" average depth of 4'.0" with a total capacity of 60,000 gallons and a normal velocity of flow of .005 feet per second. As in the case of the sedimentation tanks the influent is distributed over a weir the full length of the longitudinal section, but no sludge apron or sludge storage basin is provided.

Disinfecting Plant.—This consists of a brick built house for lime storage, mixing tanks and head orifice tank regulated to the volume of flowing sewage. The hypochlorite mixes with the sewage in a chamber 26'.0" x 4'.0" wide with baffles placed every three feet.

In laying out the plant one of the main considerations has been compactness, as all the tanks and filters are to be covered and rendered frost proof.

Most of the work has been let by contract, the city supplying the clinker. The total cost is estimated at about $80,000.

The direct supervision of the work is under the control of Mr. A. C. D. Blanchard, the City Engineer, while Mr. T. Aird Murray of Toronto, as consulting engineer, is responsible for the design and layout of the scheme.

CONTRACTS FOR THE SUPPLY OF ELECTRIC POWER FROM THE USER'S POINT OF VIEW.

V.

BY H. E. M. KENSIT, M.I.E.E.

The next points to be defined are:

(1) Nature of supply.
(2) Regulation as to voltage and frequency or cycles.
(3) Equality of load on the phases.

"Nature of the supply" should define whether it is to be 1, 2 or 3 phase or otherwise, and also the normal load and normal frequency at which the power is to be delivered.

"Regulation" should define what variation is permissible from normal voltage and frequency and what steps are to be taken if this is exceeded.

"Equality of load on the phases" refers to the arrangement of the load in the customer's works. Two phase supply requires 4 wires and gives 2 circuits. Three phase supply requires 3 wires and gives 3 circuits, and there are other combinations which need not be fully discussed here. The customer's load should be so divided amongst these circuits in his works as to be approximately equal and similar on each circuit; otherwise the regulation and efficiency of distribution will be interfered with. A want of such balance in any individual works affects not only that works but the whole of the Power Company's system.

Sample clauses on these points are as follows:—

(1) "The power supplied shall be 3 phase electric energy at 600 volts and a frequency of 60 cycles, and the wave form of the alternating current shall closely approxi-

mate a sine curve. If either voltage or frequency vary by more than 5 per cent. from that above specified for more than 10 per cent. of each consecutive 24 hours the Power Company will instal more effective regulations.

"The customer agrees, that so far as the nature of its work will permit, it will so regulate its use of electric energy that the load will not vary suddenly more than 20 per cent., and that they will maintain equality of load on the phases within 10 per cent. of the load on the least loaded phase.

"The Power Company shall not be responsible in any way for the distribution of the electric energy or power beyond the point of delivery to the customer."

The insertion of the sentence relating to "wave form" is of very doubtful utility. The point is a highly technical one requiring a mathematical explanation that would be outside the scope of this article. The "wave form" depends on the design of the generating plant and on the nature of the load and cannot be said to be under the practical control of either the Power Company or the customer.

(2) "The Power Company agrees to deliver 3 phase alternating commercially continuous 24 hour power every day of the year except as hereafter provided and in the quantities above provided, at approximately 12,000 volts and approximately 25 cycles per second frequency, and the maintenance by the Power Company of approximately the agreed voltage at approximately the agreed frequency shall constitute the supply of all power involved herein and the fulfilment of all operating obligations hereunder. When voltage and frequency are so maintained, the amount of power, its fluctuations, load factor, power factor, distribution as to phases, and all other electric characteristics shall be considered to be under the sole control of the customer."

It may be pointed out that the use of the word "approximately" is undesirable, and it is better to state a fixed percentage even if this is very liberal. In case of a dispute or legal action it is as difficult to decide what is "approximate" as what is "reasonable."

(3) "The electric energy to be delivered under this agreement shall be 3 phase, 60 cycle, 2,200 volt, alternating current, and the Power Company agrees to maintain normal frequency and voltage within 2 per cent. either way. The customer will endeavor to maintain equality of phases."

Here it may be remarked that it is extremely doubtful whether any Power Company ever has or ever will be able to maintain voltage and frequency within 2 per cent. of the normal, and it is questionable whether such a requirement could be enforced. It is better to place this at a reasonable figure, say 5 per cent., and then insist upon this being lived up to.

Variations of voltage and frequency directly affect the speed of motors, and variation of frequency also affects the power factor of the motors quite appreciably.

Such variations are more frequently downwards than upwards, due to overload of the generators or transmission line or insufficiency of power.

Lowering the voltage and thereby the speed of the motors directly affects the amount of output of the factory, and in some cases its quality, and lowering the frequency lowers the power factor, and thereby in some cases increases the amount charged for power.

The power-user should therefore keep careful watch that both voltage and frequency are kept continuously within the defined limits.

All three of the points defined at the commencement of this article can be contained in one clause, and the following is suggested as the basis of a fair clause, subject to modification to meet the particular conditions:—

"The Power Company shall supply 3 phase electric energy at a normal pressure of 600 volts, and a normal frequency of 60 cycles per second. If either voltage or frequency vary by more than 5 per cent. either way from the above stated normal pressure and frequency for more than 5 per cent. of the time in any consecutive 24 hours, the Power Company shall immediately install more efficient regulating apparatus or take such other steps as may be necessary to keep the pressure and frequency within the above defined limits. The customer agrees that he will maintain equality of load on the phases of his circuits within 10 per cent."

This clause contains a guarantee by the Power Company and a guarantee by the customer. To be effective a penalty for non-performance should be provided in each case. This might be done by providing that the amount of the account for power should be deducted from or added to in proportion to the extent to which the above limits are exceeded.

Such variations represent a cash loss; in the case of voltage and frequency the loss is to the customer in affecting the quantity and sometimes the quality of his output and lowering the power factor of his load; in the case of unequal loading of the phases the efficiency of distribution is diminished and the operating difficulties increased to the disadvantage of the Power Company; it therefore appears fair that an adjustment of the account proportionate to such variations or inequalities should be made and should work both ways.

REGISTRATION OF MEMBERS OF CANADIAN SOCIETY OF CIVIL ENGINEERS.

The following members registered too late for inclusion in the daily issue of January 26th:—

240. F. E. Bremner, Montreal.
241. A. Bertram, Dundas, Ont.
242. J. Zverina, Montreal.
243. D. MacPherson, Ottawa.
244. E. B. McLean, Moncton, N.B.
245. G. W. Shearer, Montreal.
246. W. Murdoch, St. John, N.B.
247. F. Thomson, Montreal.
248. W. H. Greene, Montreal.
249. J. Mayer, Montreal.
250. H. C. Lumsden, Toronto.
251. C. Thomson, Montreal.
252. R. W. Leonard, St. Catharines, Ont.

PERSONAL.

Mr. J. J. Antonisen, of Port Arthur, has been appointed city engineer of Moose Jaw, Sask.

Mr. J. Stoddart has severed his connection with the city of Toronto. He has been appointed assistant engineer in the waterworks department of Hamilton, Ont.

OBITUARY.

Mr. Matthew Neilson, a well-known civil engineer in Canada, died on January 21st at his residence, 52 Arlington Avenue, Westmount, Montreal, after an illness of three months. Mr. Neilson was born at Almonte, Ont., 59 years ago. He is survived by a widow and one son. His death was due to pleuro-pneumonia.

FORESTRY CONVENTION.

The program for the big Forestry Convention, at Ottawa, February 7th and 8th, is now complete. The subject of how to handle our forests so as to get the most out of them, both now and in the future, will be dealt with by leaders from Canada and from the United States. Among those who will speak are Messrs. Gifford Pinchot, formerly Chief Forester of the United States; E. A. Sterling, Forester of the Pennsylvania Railroad, which is now growing its own ties; Dr. Fernow, head of Forestry School, of Toronto University; Dr. J. W. Robertson, of the Conservation Commission, and H. R. MacMillan of the Forestry Branch of the Department of the Interior. The banquet on Wednesday evening will be attended by parliamentary leaders, educationists, foresters, lumbermen and the heads of financial and commercial institutions. The day sessions are open to the public, and the importance which the government attaches to this subject is shown by the fact that these are held in the Railway Committee room of the Parliament Buildings; while the railways have granted special rates to delegates. The Seed Growers' Association convene on February 8th and 9th, so that delegates to the Forestry Convention will be able to attend some of the sessions of that body.

COMING MEETINGS.

THE CANADIAN SOCIETY OF CIVIL ENGINEERS.—Jan. 24. 25, 26, 1912. General meeting. 413 Dorchester St. West, Montreal. Prof. C. H. McLeod, Secretary.

CANADIAN FORESTRY ASSOCIATION.—February 7th and 8th, 1912. Forestry Convention Meetings held in the Railway Committee Room, Parliament Buildings, Ottawa. Secretary, Mr. James Lawler, Canadian Bldg., Ottawa.

CANADIAN LUMBERMEN'S ASSOCIATION.—February 6, 7 and 8, 1912. Annual Meeting to be held at the same time and place as the Canadian Forestry Association.

CANADIAN NATIONAL ASSOCIATION OF BUILDERS. — The Sixth Annual Convention will be held in Toronto, February 20, 1912.

ONTARIO GOOD ROADS ASSOCIATION.—Annual Convention to be held at Toronto, February 26, 27, 28. Secretary, J. E. Farewell, Whitby.

THE CLEVELAND ENGINEERING SOCIETY.—Regular Meeting, Tuesday Evening, February 13, 1912, Chamber of Commerce Bldg., Cleveland, O. Address by Mortimer E. Cooley, Dean, Department of Engineering, University of Michigan; Subject: "Public Utilities and Their Relation to the Public." Secretary, F. W. Ballard.

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, C. H. Rust; Secretary, Professor C. H. McLeod.

QUEBEC BRANCH—
Chairman, P. E. Parent; Secretary, S. S. Oliver. Meetings held twice a month at Room 40, City Hall.

TORONTO BRANCH—
96 King Street West, Toronto. Chairman, T. C. Irving; Acting Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the month at Engineers' Club.

MANITOBA BRANCH—
Secretary E. Brydone Jack. Meets every first and third Fridays of each month, October to April, in University of Manitoba, Winnipeg.

VANCOUVER BRANCH—
Chairman, Geo. H. Webster; Secretary, H. K. Dutcher, 319 Pender Street West, Vancouver. Meets in Engineering Department, University.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, S. J. Chapleau, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

MUNICIPAL ASSOCIATIONS.

ONTARIO MUNICIPAL ASSOCIATION.—President, Chas. Hopewell, Mayor, Ottawa; Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

UNION OF ALBERTA MUNICIPALITIES.—President, H. H. Gaetz, Red Deer, Alta.; Secretary-Treasurer, John T. Hall, Medicine Hat, Alta.

THE UNION OF CANADIAN MUNICIPALITIES.—President, W. Sanford Evans, Mayor of Winnipeg; Hon. Secretary-Treasurer, W. D. Lighthall, K.C., Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer, J. W. McCready City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. E. McMahon, Warden, King's Co., Kentville, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secretary, Mr. Heal, Moose Jaw

CANADIAN TECHNICAL SOCIETIES.

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang; Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BUILDERS, CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto.

CANADIAN ELECTRICAL ASSOCIATION.—President, N. W. Ryerson, Niagara Falls; Secretary, T. S. Young, Canadian Electrical News, Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, Thomas Southworth, Toronto; Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; J. Keillor, Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. Frank D. Adams, McGill University, Montreal; Secretary. H. Mortimer-Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, T. A Starkey, M.B., D.P.H., Montreal. Secretary, F. C. Douglas, M.D., D,P.H. 51 Park Avenue, Montreal.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, D. McDonald, Manager, Montreal Street Railway; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto, President, G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July, August.

DOMINION LAND SURVEYORS.—President, Thos. Fawcett, Niagara Falls; Secretary-Treasurer, A. W. Ashton, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, W. B. McPherson; Corresponding Secretary, A. McQueen.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President, Killaly Gamble; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian Members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain, and W. H. Miller, and Messrs. W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary, R. C. Harris, City Hall, Toronto.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C.B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, W. H. Pugsley, Richmond Hill, Ont.; Secretary, J. E. Farewell, Whitby.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, J. Whitson; Secretary, Killaly Gamble, 703 Temple Building, Toronto.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary J. E. Ganier, No. 5. Beaver Hall Square, Montreal.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, F. S. Baker, F.R.I.B.A., Toronto, Ont.; Hon. Secretary, Alcide Chausse, No. 5 Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Dr. A. McGill, Ottawa, President; Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, J. P. McRae; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Wm. Pierce, Calgary; Secretary-Treasurer, John T. Hall, Brandon, Man.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. Rosevear, 115 Phœnix Block, Winnipeg, Man. Second Monday, except June, July and August, at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc.
Printed forms for the purpose will be furnished upon application.

TENDERS PENDING

In Addition to Those in this Issue.

Further information may be had from the issues of The Canadian Engineer referred to.

Place of Work.	Tenders Close.	Issue of.	Page
Arcola, Sask., schoolhouse	Feb. 1.	Jan. 18.	75
Calgary, Alta., bridge	Feb. 10.	Jan. 18.	86
Chesley, Ont., public wharf	Jan. 31.	Jan. 18.	75
Grandview, Man., scrapers	Feb. 1.	Jan. 18.	75
Hamilton, Ont., works supplies	Feb. 6.	Jan. 25.	59
Lajord, Sask., schoolhouse	Feb. 10.	Jan. 25.	59
Little Lameque, N.B., wharf	Feb. 14.	Jan. 25.	59
Lake Quinze, Que., dams and sluiceways	Feb. 15.	Jan. 25.	59
Lloydminster, Sask., public building	Feb. 7.	Jan. 25.	59
Lion's Head, Ont., lighthouse tower	Feb. 5.	Jan. 18.	75
Ottawa, Ont., iron posts	Jan. 31.	Dec. 21.	68
Ottawa, Ont., contracting machinery	Feb. 26.	Jan. 11.	59
Petewawa, Ont., improvements to wharf	Jan. 31.	Jan. 18.	75
Saskatoon, Sask., subway	Feb. 23.	Jan. 25.	68
Saskatoon, Sask., pavements	Feb. 16.	Jan. 18.	86
Saskatoon, Sask., concrete sidewalks	Feb. 16.	Jan. 18.	86
Swift Current, Sask., theatre	Feb. 16.	Jan. 25.	59
Toronto, Ont., bridges	Jan. 31.	Jan. 18.	75
Toronto, Ont., Central Y.M.C.A. building	Feb. 5.	Jan. 25.	60
Toronto, Ont., track intersections, etc.	Feb. 20.	Jan. 25.	72
Upper Salmon River, N.B., pier	Feb. 14.	Jan. 25.	59
Victoria, B.C., schoolhouse	Jan. 31.	Jan. 18.	75
Walkerton, Ont., bridge, Saugeen River	Jan. 23.	Jan. 4.	59
Winnipeg, Man., electric vehicle	Feb. 1.	Jan. 18.	75
Winnipeg, Man., drawings for Parliament Buildings	Mar. 31.	Jan. 25.	70
Winnipeg, Man., pumping machinery	Mar. 1.	Jan. 25.	72

TENDERS.

Calgary, Alta.—Tenders for sluice gates will be received by A. S. Dawson, chief engineer, C.P.R. Irrigation Department, Calgary, until February 29th, 1912. (See advertisement elsewhere in Canadian Engineer.)

Galt, Ont.—Tenders will be received until February 24th, 1912, for the construction of a building for the Young Men's Christian Association, on Queen's Square, Galt. Plans and specifications may be seen at the office of the General Secretary, William R. Cook, of the Young Men's Christian Association, Water Street, Galt, Ont.

Halifax, N.S.—L. Fred Monaghan, City Clerk, will receive tenders until February 1st, 1912, for 4,000 ft. 2½-in. fire hose, and 300 ft. 1-in. chemical hose, all with couplings complete and suitable for Halifax Fire Department.

Kerrisdale, B.C.—Tenders will be received until February 19th, 1912, for the supply of valves, hydrants and special castings, for the Corporation of Point Grey water supply. Specifications, etc., at the office of the engineers, Messrs. Cleveland & Cameron, 506 Winch Bldg., Vancouver. H. Floyd, C.M.C., Municipal Hall, Kerrisdale.

Lethbridge, Alta.—Tenders will be received until February 15th, 1912, for the construction of an extension to power house, plans and specifications of which may be obtained from A. Reid, General Supt., City Hall, Lethbridge. G. W. Robinson, Secr.-Treas., Lethbridge.

London, Ont.—Tenders will be received until February 14th, 1912, for one 50 h.p. gas engine, one gasoline engine, two half-million gallon triplex pumps, three deep well pumps, etc. F. W. Farncomb, Consulting Engineer, London. (See advertisement elsewhere in Can. Eng.)

Ottawa, Ont.—The Dept. of Public Works will receive tenders for the construction of a wharf at Cap St. Ignace, Que., until Feb. 5th, 1912. Plans, etc., at the offices of A. R. Decary, P.O. Bldg., Quebec; J. L. Michaud, Merchants Bank Bldg., St. James St., Montreal.

Ottawa, Ont.—Tenders will be received until February 24th, 1912, for the construction of five twin-screw gasoline launches for the Fishery Patrol Service of the Maritime Provinces of the Dominion of Canada, of the following dimensions:—

Length over all	45 feet.
Breadth moulded	11 feet.
Mean load draft	3 ft. 2 in.

Each boat to be equipped with two 16-h.p. gasoline engines. Plans, etc., can be obtained on application from the Purchasing and Contracting Agent, Marine Department, Ottawa. Agents, Marine Department, St. John, Halifax and Charlottetown. A. Johnston, Deputy-Minister of Marine and Fisheries, Department of Marine and Fisheries, Ottawa.

Ottawa, Ont.—Tenders for the construction of an extension to East Breakwater, and removal of L on West Breakwater, and dredging of Meaford, Grey County, Ontario, will be received until February 26th, 1912. Plans, etc., can be obtained at the offices of H. J. Lamb, District Engineer, Windsor, Ont.; J. G. Sing, District Engineer, Confederation Life Building, Toronto; Postmaster at Meaford, Ont., and at the Department of Public Works, Ottawa.

Winnipeg, Man.—Tenders will be received until February 14th, 1912, for extending the piers and abutments of the Red River Bridge, Winnipeg. Plans, specifications and forms of proposal can be seen at the office of Frank Lee, Division Engineer, Winnipeg.

Sudbury, Ont.—Tenders will be received until 1.00 p.m. February 5th, 1912, for the furnishing and installation of 2 return tubular boilers 72 in. x 18 ft. with accessories; also for 2 horizontal compound duplex steam pumps, 900 Imperial gallons capacity each; also one twelve-inch Venturi Water Meter. J. G. Heney, Esq., Mayor.

Toronto, Ont.—Tenders will be received until March 2nd, 1912, for the construction of 12 concrete bridges in East Whitby Township, Ont. Engineers, Bowman & Connor, 36 Toronto Street.

Winnipeg, Man.—Tenders will be received until February 8th, 1912, for the supply and installation of 3-50 K.W. transformers and accessories at Well No. 3, specifications, etc., of which may be obtained at the office of the City Engineer, 223 James Ave. M. Peterson, Secretary, Board of Control Office, Winnipeg.

Victoria, B.C.—Tenders for the erection and completion of a five-room two-cell lock-up and constable's quarters at Quathiaski Cove, Valdes Island, in the Comox Electoral District, B.C., will be received till February 7th, 1912. Plans at offices of Government Agents, Cumberland and Nanaimo; the Constable-in-Charge, Quathiaski Cove, and the Dept. of Public Works, Parliament Bldgs., Victoria.

CONTRACTS AWARDED.

Calgary, Alta.—Messrs. McDougall & Foster have closed a contract for the erection of an apartment building to cost $250,000, to be erected at the corner of Jasper Avenue and Twenty-third Street, Edmonton, Alta.

Point Grey, B.C.—Contractors MacAdam & Co., of Vancouver, have the contract of the construction of a vitrified brick sewer on West Boulevard. Cost, $27,412.

Quebec, P.Q.—Mr. M. Connelly, of Montreal, has been awarded the contract to lay the Quebec water mains. Messrs. R. Maclaren Company of Glasgow will supply the fittings. This is the largest cast-iron pipe contract ever awarded in Canada ($532,000.)

Victoria, B.C.—The contract for the construction of the new six-story fireproof rooming house on Johnston Street for Messrs. Chas. Hayward and F. S. Barnard, has been awarded to the Westholme Lumber Co. The plans provide for stores with commodious basements on the ground floor, the upper portion to contain 100 good-sized rooms, each provided with hot and cold water, bath room, etc., and each furnished with telephone. The entire building is to be heated with steam, and electric lighted throughout, while an elevator in the main entrance will provide easy access to every flat. The entire cost of the building is $112,000.

Victoria, B.C.—The owner, P. R. Brown, has let a contract for about $14,000 to the Westholme Lumber Company for alterations to the premises on Douglas Street, between Fort and Broughton Streets.

Walkerton, Ont.—The Hunter Bridge Co., of Kincardine, have the contract for the erection of a steel bridge over the Saugeen River, Brant Township. James Warren, Engineer-in-charge.

RAILWAYS—STEAM AND ELECTRIC.

Brantford, Ont.—The Dominion Railway Board has approved the general location of the Lake Erie and Northern electric line to Port Dover, Ont.

Province of British Columbia.—The Dominion Railway Commission have approved the plans submitted by the Esquimalt and Nanaimo Railway Company for its extension up the east coast of Vancouver Island from Union Bay to Duncan Bay, the latter a point north of the Campbell River. It is understood that a very early commencement of construction is contemplated by the compnay, the clearance of right-of-way and a beginning of the grading of the line being already in hand. Large terminals are contemplated for Duncan Bay.

Edmonton, Alta.—Two petitions were brought before the house for the incorporating of street railway companies, one in Medicine Hat and another to serve several of the Crow's Nest towns. The Crow's Nest Pass Street Railway Company wants to operate lines from Cowley, west through Lundbreck, Burmis, Passburg, Bellevue, Frank, Blairmore, Coleman, to a point near Crow's Nest Lake. Those promoting the scheme are given as W. A. Beebe, Robert Coulthard, and Thomas B. George, all of Blairmore. The company is capitalized at half a million. Bonds may be issued to the extent of $12,000 a mile, and work is to start within two years and be completed in five. The Medicine Hat Railway Company's petition was brought in on behalf of Albert F. Krappel, David W. Brown and Warren Overplank, all of Medicine Hat. They are asking for the right to operate lines within Medicine Hat and suburban lines, including Dunmore and south-east to Elkwater Lake.

Montreal, P.Q.—It is stated that by early spring another railway, the Central of Canada, from Montreal to Ottawa, will be under construction, the contracting firm, Messrs. C. J. Wills & Sons, of London, being represented in this city by Mr. David Lyell. Orders are now being given for all the ties needed, as well as for the steel rails which are to be eighty pounds to the yard. It is said that a double track will be laid from Montreal as far as St. Eustache. The construction of three heavy bridges at the Back River, St. Eustache and at St. Andrews will be commenced when the spring opens, and by fall most of the masonry will have been placed in position. The entrance into the City of Montreal has not yet been disclosed by the company.

New Waterford, N.B.—The Dominion Coal Company have under construction at Carney's Lake, near New Waterford, a new electric power station to supplement their central electric power plant at Dominion No. 2. The work is being done by the company's construction staff, under the direction of Superintendent J. S. White.

Ottawa, Ont.—A report states that Hon. C. J. Dougherty, minister of justice, announced that the government has decided not to disallow the legislation of the Alberta Government in regard to the Alberta and Great Waterways Railway. The Provincial Government passed a bill taking over the $7,000,000 raised by the company on its bonds, and disallowance was asked for the reason, that it would be against established precedent to disallow such legislation, the rule having been established that it is inadvisable to interfere with the provinces in the administration of purely provincial affairs. Steps will be taken, it is understood, to see that the interests of those who have claims against the province are protected.

Province of Saskatchewan. — A network of railways to connect all four of the cities of the province with the Hudson Bay Railway is the evndent intention of the Canadian Northern Railway, according to a petition to be presented to the legislature.

Saskatoon, Sask.—During an attempt to wreck the C.P.R. train from Winnipeg to Edmonton, a bridge 93 miles west of Saskatoon was burnt by some persons unknown.

Saskatoon, Sask.—The city council approved the plans submitted by A. G. Sangster, electrical superintendent, to install three hundred and fifty-five light Tungsdon standards on the principal business streets of the city.

Western Canada.—W. B. Lanigan, general freight agent of the C.P.R. has been in St. Paul to borrow motive power to move from Fort William and Port Arthur 3,000,000 bushels of wheat still unmoved, which was ordered out for January delivery. He was negotiating with Great Northern and Northern Pacific Railways.

LIGHT, HEAT AND POWER.

Berlin, Ont.—The Light Commissioners have the following for sale:—One Westinghouse Gas Engine, size 19 x 22, 250 h.p., direct connected to 150 k.w. 3 phase 60 cycle 2,200 volt generator; also direct connected exciter. One 3 cylinder vertical Westinghouse Gas Engine, rated 90 h.p., size 10 x 11. Three 3 cylinder vertical Westinghouse Gas Engines, 125 h.p., size 13 x 14. One Tandem Compound Wheelock Engine 10 x 18 x 28, rated 125 h.p. Also a number of motors and generators.

Fredericton N.B.—The city council are to make an effort to secure a capable official to take charge of the electric light plant.

Carmangay, Alta.—The council have received word that the engine and boiler for the waterworks and electric light plants had been shipped. In two or three weeks the electric light plant should be in operation.

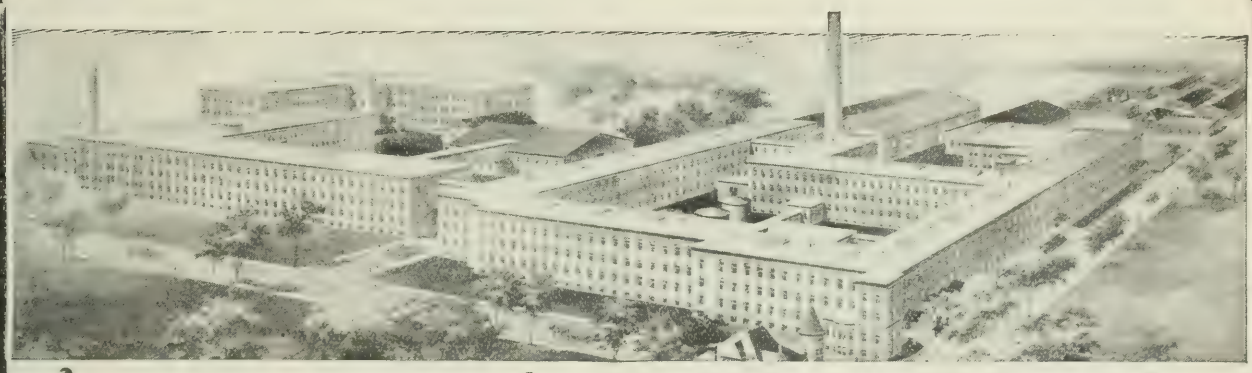
Port Arthur, Ont.—The work on the new street lighting system has been held back owing to the extreme cold weather.

Stave Falls, B.C.—The first large unit installed by the Western Canada Power Company, Stave Falls, B.C., was started on the 16th of December last. The putting into operation of this largest unit installed in Canada (excepting to Niagara Falls), went on to the greatest satisfaction and no irregularity whatever was experienced. No adjustment whatever was necessary, and the turbine was not again shut down. The present installation comprises two units of 13,000 horse-power, each working under a head of about 110 feet. The hydraulic equipment is supplied by Messrs. Escher Wyss & Company of Zurich, Switzerland. Canadian office, 408 Lumsden Building, and the electrical end by the Canadian General Electric Company of Canada.

Tweed, Ont.—The Tweed Electric Light and Power Company, controlled by the Messrs. Kisack Bros., have sold out to the Tweed Electric Light and Power Company, Ltd. The Electric Power Company of Toronto have the controlling interest, and new developments will take place in the system during the spring. Tweed is in Hastings County, Ont.

Quebec, P.Q.—A contract has been made between the municipality and the Dorchester Electric Company by which the Dorchester Electric Company engaged to do the city

Barrett Specification Roofs



Warner Bros. Co., Corset Manufacturers, Bridgeport, Conn. Day & Zimmerman, Engineers, Philadelphia, Pa.

The Most Economical Roof

FOR half a century architects have known that slag and gravel roofs would *often* show marvelous durability.

The Barrett Specification defines the method by which these roofs may be built so that they will *always* show such durability.

It provides for the best materials manufactured, and prescribes the most approved methods of application.

A Barrett Specification Roof will cost less than any other permanent roof, will last upwards of twenty years and will need no painting or coating or care. Such roofs are fire-retardant and take the base rate of insurance.

That is why they are invariably used on large manufacturing plants where the roof areas are great and where, therefore, the unit costs are carefully studied.

Booklet giving the Barrett Specification in full mailed free on request. Address nearest office.

Special Note

We advise incorporating in plans the full wording of The Barrett Specification, in order to avoid any misunderstanding.

If an abbreviated form is desired however the following is suggested:

ROOFING—Shall be a Barrett Specification Roof laid as directed in printed Specification, revised August 15th, 1911, using the materials specified, and subject to the inspection requirement.

The Paterson Manufacturing Co., Limited

Montreal Toronto Winnipeg Vancouver St. John, N.B. Halifax, N.S.

lighting at seven cents per kilowatt hour. The contract with the Quebec Railway Light and Power Company expired on August 1 last, so that the new company will at once begin to put in their plant. Tenders will be called for in the near future.

Vancouver, B.C.—Gigantic power development is to be undertaken by the British Columbia Electric Railway Company during the present year. The plans are for the development during the present year of the generating station on the North Arm of Burrard Inlet, so as to make an available output from the plant of 85,500 horse-power. This practically means the doubling of the present output of this station. The plans at the Lake Buntzen plant and the North Arm station indicate that by the end of 1912 the company will probably have an available output of 105,000 horse-power. Plans are in hand for future developments of power sites controlled by the company which will bring its available output up to 200,000 horse-power.

SEWAGE AND WATER.

Aylmer, Que.—It is proposed to construct a septic tank to treat the sewage from the town before it is emptied into the Ottawa river. The estimated cost of the tank is $5,000 and the city of Ottawa has expressed its willingness to provide $2,500 towards the work. The town of Aylmer will supply the balance. Mr. Ker, City Engineer, Ottawa.

Brandon, Man.—Mayor Fleming in his opening address to the council stated that the waterworks system will be reorganized during the year 1912.

Halifax, N.S.—Since the installation of water meters, according to reports from the lakes, the large meters on the mains show that whereas a year ago the city consumption was about 2,250,000 gallons per day, now it is about 1,600,000 gallons per day. A very large saving.

Medicine Hat, Alta.—A scheme for building a reservoir in this city, with a capacity of 40,000,000 gallons, will be brought up before the city council in the near future. W. P. Morrison, Engineer.

Moose Jaw, Sask.—The water supply is holding out as well as may be expected for this time of the year. The Snowdy Springs and Ross Crescent supplies are still producing fairly well.

St. Catharines, Ont.—Recent examination of the drinking water showed infection to be absent.

Vancouver, B.C.—City Engineer Fellowes recommended that the four-foot brick and concrete sewer on Dufferin Street be extended from Yukon to Bridge, also the construction of a three-foot sewer on Bridge from Dufferin to Seventh Ave. The estimated cost of this work by day labor is $17,300

BUILDING.

Calgary, Alta.—Work will commence in the spring of 1912, on the grounds and buildings of the Calgary University. Rev. Dr. Braithwaite, of Toronto, has been appointed Dean.

Calgary, Alta.—The Rumley Machine Company of Laporte, Indiana, manufacturers of gas traction engines and other machinery, have purchased a site consisting of 25 acres of trackage property in this city. It is the intention of the company to establish a manufacturing plant on the property.

Listowel, Ont.—The Listowel agricultural society will spend $2,000 on erecting a new building on the fair grounds.

Montreal, P.Q.—The congregation of Westmount Methodist Church are contemplating the erection of a $120,000 structure. Rev. W. E. Baker, Pastor.

Port Arthur, Ont.—The city engineer's office have prepared preliminary plans for a fire station to cost about $25,000, also a telephone exchange building to cost about $24,000.

Port Stanley, Ont.—Speakers at the meeting of the London, Ont., board of trade suggested the necessity of the construction of a grain elevator at Port Stanley.

Saskatoon, Sask.—A company which will engage in the manufacture of Trojan flooring and fireproof partitions will erect a factory in this city. Mr. C. H. Forrester, of the International Construction Company, Winnipeg, Man., is interested in this project.

Toronto, Ont.—Work on the new St. Alban's Cathedral will commence in the spring. Messrs. Symons & Rae, local architects.

Vancouver, B.C.—Mr. J. D. Barton, New York, U.S.A., is contemplating the erection of an apartment house in this city to cost $250,000.

Winnipeg, Man. — The Canadian Consolidated Rubber Company and the Canadian Fairbanks Morse are about to erect large factories in the west end of the city.

ROADS AND PAVEMENTS.

Vancouver, B.C.—The city engineer, Mr. Fellowes, recommended to the council that tenders be called for the construction of a wood block pavement on Seymour Street from Robson to Pacific, and on Richards between the same two streets.

BUSINESS.

Bancroft, Ont.—$18,000 damage was caused by fire to several industries in this town. The buildings damaged included S. Plew's grist mill, D. Fuller's woollen mill, J. D. Payne's machine shop, and the electric light plant.

Province of British Columbia.—The British Columbia Fishery Company, of London, England, was recently organized with a capital of one million dollars for the exploitation of the deep sea fisheries of the Pacific coast off Queen Charlotte Islands. The company will engage in the salmon-fishing industry, and canning as well as in halibut, cod and herring fishing, and will establish canneries and plants for manufacturing by-products.

Montreal, P.Q.—A fire which broke out at the premises of Shearer, Brown & Wills Company, Ltd., lumber merchants, did damage to the extent of $80,000.

Trenton, Ont.—Fire damaged the opera house and a grain elevator owned by Mr. J. G. Squier. The machinery of the City Steam Laundry was also damaged. The estimated losses, $12,000.

Minitonas, Man.—J. D. Ramsay's general store was gutted by fire. More than $10,000 in stock was carried, and two-thirds of it was a total loss.

Victoria, B.C.—The estimates for the year for the fire department amount to $105,409, of which $68,716 is for salaries. The recommendation was made and adopted that twelve new alarm boxes and 4,000 feet of hose be purchased.

Yorkton, Sask.—The power plant and electric light system were seriously damaged by fire. A. C. Crasly, town engineer.

CURRENT NEWS.

Province of British Columbia.—The Forest Act brought down in the provincial legislature is an exceedingly comprehensive measure, comprising 144 sections. Among other measures it proposes to create what is to be known as the forest branch of the department of lands, to be presided over by a chief forester, with such assistance as he may require.

Calgary, Alta.—The present value of the equipment of the fire department is $291,670, made up of the following items: Equipment, $60,450, horses, harness, etc., $19,250; alarm system, $18,765; furniture, $2,600; buildings and land, $19,605.

Guelph, Ont.—A conference has been held between the municipal officials and the Canadian Pacific Railway, with a view of beautifying the railroad properties around the city.

Kingston, Ont.—That the city council purchase the Cataraqui bridge, and that the necessary by-law be prepared was the recommendation made by the civic finance committee.

Ottawa, Ont.—Representations have been made to the government for the appointment of a special commission to enquire into the lead-zinc industry. The lead bounty expires

MODERN ELEVATORS

FOR FREIGHT OR PASSENGERS

PLUNGER. —Our plunger elevators embody patented features such as a new main valve which prevents bounding when the car stops, and a new control valve which prevents any accidental movement of the car in the opposite direction when passengers are entering or leaving.

ELECTRIC. —Our electric elevators have patented improvements embodying the good features of the drum and traction type and eliminating their bad ones, and giving greater security and economy of operation. These elevators are worthy of the attention of all interested in office and factory building.

in June and it is desired that in place of waiting for the tariff commission special enquiry be made meanwhile.

Province of Quebec.—Premier Gouin has opened negotiations with the government at Ottawa, looking to the acquisition of the territory known as Ungava, and its annexation to the Province of Quebec. The district is supposedly rich in minerals, fairly fertile, and adapted to colonization.

Toronto, Ont.—An estimate for the extension of Teraulay street has been prepared. The extension as proposed would be about three-fifths of a mile and would cross nine streets in the residential section. The cost is placed at $200,000.

Victoria, B.C.—$750,000 is the amount asked for by the council to carry on the civic business until the taxes are due.

Winnipeg, Calgary and Edmonton.—Notice comes from Ottawa that examinations will be held at Winnipeg, Calgary and Edmonton on February 12, 1912, of candidates for positions as Dominion land surveyors.

TRADE ENQUIRIES.

The following were among the inquiries relating to Canadian trade received at the office of the High Commissioner for Canada, 17 Victoria street, London, S.W., during the week ending January 8th, 1912:—

A London firm desire to appoint agents at Montreal, Toronto, Winnipeg and other large centres in Canada, for the sale of a hygienic system of air purification suitable for theatres, picture halls, hospitals, schools, homes, etc.

A Yorkshire firm manufacturing druggists' sundries and surgical appliances, desire to get into touch with Canadian importers.

A London firm having a demand for best three-ply pine or similar three-ply wood, ask for names of Canadian manufacturers.

A West of England firm of dairy and agricultural engineers desire to get into communication with agents in Canada handling cheese-making appliances.

A firm in the West of England are in the market for supplies of tool handles of various kinds.

A London firm having a well-established connection amongst wholesale provision merchants, wish to get into correspondence with Canadian butter and cheese shippers requiring representation in Great Britain.

A correspondent in the province of Quebec is desirous of getting into touch with United Kingdom importers of Canadian hay.

A correspondent who is shortly returning to Canada is desirous of getting into touch with United Kingdom manufacturers requiring a resident agent in the Dominion; wishing to open a branch factory; open to see Canadian patent rights. Engineering, chemical or textile industries preferred.

The Canadian agent of an English manufacturer of condiments and essences is open to take up another line which he could work in conjunction.

A Montreal importer desires to obtain agencies for fancy goods.

A Winnipeg manufacturers' agent wishes to secure agencies for felt-shoe findings, house furnishings and builders' materials.

Inquiry is made by a Canadian correspondent now in Wales for the names of manufacturers of fancy leather goods requiring Canadian representation.

From the branch for City Trade Inquiries, 73 Basinghall Street, E.C.:

A German firm manufacturing pyrenees lambs-wool flannels (fleeces, ripples, naps, etc.), are seeking Canadian agents.

A Liverpool firm ask to be placed in touch with Canadian shippers of dried fish.

The following were among the inquiries relating to Canadian trade received at the office of the High Commissioner for Canada, 17 Victoria Street, London, S.W., during the week ending January 15th, 1912:—

A London firm of small pipe organ manufacturers desire to open up business in Canada.

A London firm, stated to have a large market for Canadian rolled oats, wish to get into touch with some millers in the Dominion able to deal with large orders.

A London firm seek an agent in Canada for the sale of a street fire alarm system, and time-saving devices for fire stations.

A Scottish firm make inquiry for the names of Canadian buyers of Toe Calk steel.

A Yorkshire firm make inquiry for the names of Canadian miners of iron ore, who may be open to appoint an agent in Great Britain.

A Montreal chemist controlling a wholesale and several retail businesses in the city, is open to act as agent or manager of the Canadian branch of a first-class United Kingdom manufacturer. A London representative would call on interested parties.

A Montreal dealer in typewriter and duplicator supplies is open to correspond with United Kingdom manufacturers of these goods.

A Calgary correspondent, now in London, is open to take up agencies for heavy hardware, mine, mill and builders' supplies, iron and steel.

A Toronto correspondent would like to hear from United Kingdom importers of maple and birch logs in the round; also buyers of wood flour and excelsior; and buyers of maple and birch timber in the square.

A London correspondent who is shortly leaving for British Columbia, is desirous of securing agencies for the sale of paints, varnish, brushes, enamel baths, basins, sinks, galvanized cisterns, galvanized wire, nails, sheets, general ironmongery and house furnishings, stoves and boilers, wallpapers, glass, enamel tiles and other building materials.

From the branch for City Trade Inquiries, 73 Basinghall Street, E.C.:—

A London paper agent, who is about to visit Canada, and who claims an established connection among buyers of paper of various kinds, would be glad to get into touch with actual Canadian manufacturers of paper who are in a position to fill orders for export.

A London firm are open to purchase large quantities of cardboard milk bottle caps and invite quotations from Canadian manufacturers.

A Canadian company who are in the market for quantities of commercial sodium phosphate and ammonium chloride, invite quotations from manufacturers of these chemicals.

A manufacturers' agent in Montreal desires the addresses of manufacturers of orange-red mineral and of blanc fix for coating purposes on paper.

PATENTS.

The following is a list of patents granted to inventors in Canada. This list is furnished by Messrs. Fetherstonhaugh & Company, 10 King Street East, Toronto:—

F. J. Alderson and W. H. Dunsmore, shocking machines; C. M. Conklin, students' chair; W. Nepean-Hutchison, lock washers; A. Lemieux, price tags; G. W. Mallory, animal bits; H. L. Mason, trousers; W. C. Weeks, gravel washers.

The following is a list of Canadian patents recently issued through the agency of Messrs. Ridout & Maybee, Manning Chambers, Toronto:—

Sir C. C. Wakefield, force feed lubricator; C. H. Sivel, safety apparatus for mining cages, lifts and the like; Wilhelm Gunther, process of treating ores; W. U. Jackson, H. Lloyd, and S. F. Murrell, tube making machinery; Friedrich Stamuschulte, recuperator; E. H. Nutter and H. Lavers, ore concentration (fractional flotation); C. V. Thierry, metallurgy of zinc; Emil Fleischer, process and apparatus for making steel; L. Sunderland, and G. C. Pillinger, electrical control of engines, dynamos and batteries; A. E. Tilburn, fountain brush; G. H. Robinson, packing for piston rods or the like; Samuel Aikins (re-issue), door knobs; J. H. Garbutt and W. J. Kemmis, seed covering attachment for drils; H. Brune and H. Horst, process of drying raw peat; W. H. Baxter, stone washing machinery; R. C. Quin, fenders for rolling stock; C. B. Redrup, fluid pressure engines or pumps.

Two Great Needs Filled

Goodyear Sheet Packing for High or Low Pressure
Magnet High-Pressure Gasket Tubing

After months of painstaking experiment we have perfected Sheet Packing and high-pressure *Gasket Tubing* that forever *do away* with the disappointment, trouble and expense caused consumers by the many cheap and worthless grades that have been placed on the market.

Magnet Sheet Packing

Made of the celebrated Magnet compound, this packing is totally *unaffected by heat, oil, liquor (ammonia), alkali, or by expansion or contraction.*

It is suitable for high or low pressure uses, particularly high, because of its heat-resisting properties. It neither becomes hard nor brittle. Retains its tough, elastic efficiency for months.

Magnet Sheet Packing won't *blow out.* It makes a tight joint that stays tight under air, hot or cold water or strain pressure.

Meets every requirement.

No engine room, locomotive, steamboat or machine shop is properly equipped without a roll of this great emergency packing.

GOODYEAR

Magnet High-Pressure Gasket Tubing

Made also from the celebrated Magnet compound. Forms a tight joint no matter how rough the surface may be—and it is

Pressure-Proof

Magnet Gasket Tubing can't blow out. Like Magnet Sheeting, it successfully resists any degree of steam heat and it maintains its elasticity.

Cut to Fit

One of the big advantages of Magnet Gasket Tubing is that it may be cut any length to fit any size manhole or handhole, plate or pipe flange. Cut ends joined together with rubber core, making *continuous gasket.* Put up in convenient boxes with rubber core and tape.

If you need sheet packing or gasket tubing, grasp this opportunity. The Goodyear trade-mark stands for reduced first cost and economy all along the line. It stands for the same quality workmanship that underlies the success of the Goodyear Tire & Rubber Company, Akron, Ohio, one of the best known and most experienced manufacturers of rubber goods in the world. In all of our business in Canada last year, we had to replace, because of slight defects, only $155.22 worth of goods.

MEETINGS.

At an address given before the Engineers' Society of the University of Manitoba, Hon. R. P. Roblin, honorary president, remarked that engineering is as old as history. We have records of magnificent engineering feats from the hanging walls of Babylon and the reclamation of the desert by the Pharaohs down to the present day. While the Province of Manitoba is at present handicapped from providing adequate facilities for education and instruction in your profession still you can now get the principles here as well as at any other university on the continent. A man may be graduated with honors but still be an absolute failure. The foundations necessary to a man are character and reputation. Have character as the keystone of your life's work. The opportunities in the west are many. Electricity is one of the greatest adjuncts of civilization, and its possibilities are illimitable, in which connection might be mentioned the great asset of water power which we have. There is a rich and fertile field before you.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA.

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from The Canadian Engineer for small fee.

15788—January 12—Authorizing C.N.R. to open for carriage of traffic its line from Groose Isle, Man., to end of track, 31 miles, fencing, etc., to be completed by August 1, 1912.

15789—January 12—Authorizing G.T.R. to reconstruct bridge No. 39 at mileage 216.51, 18th District, over Pike's Creek, Ont.

15790—January 4—Authorizing C.N.O. Ry. to take property of Joanna Britnell, in City of Belleville, Ont., for diverting Bay Street.

15791—January 10—Authorizing C.P.R. to reconstruct bridge No. 43.8 on Farnham Subdivision, Montreal Terminals.

15792—January 13—Authorizing Government of British Columbia to construct highway crossing over track of Columbia & Western Ry. at Eholt, B.C.

15793—January 13—Authorizing C.P.R. to operate and construct spur for Standard Fish & Fertilizer Co., Calgary, Alta.

15794—January 11—Authorizing C.P.R. to construct its Kerrobert Northeasterly Branch across highways from mileage 1.52 to 19.16, Saskatchewan.

15795—January 12—Authorizing C.N.R. to use for construction purposes only until July 1, 1912, crossing with its Deslisle Extension of track of C.P.R. Moose Jaw-Lacombe Branch.

15796—January 11—Authorizing C.N.R. to construct spur into plant of Saskatoon Milling & Elevating Co., Saskatoon, Sask.

15797-98-99—January 15—Authorizing C.N.O. Ry. (Sudbury-Port Arthur Line and Montreal-Port Arthur Line) and approving locations through unsurveyed territory, District of Algoma, mileage 327 to 343.15 from Sudbury Jct., through Twps. of Nepean, March and Torbolton, County of Carleton, Ont., mileage 14.3 to 27 from Ottawa, and through Twps. of Ross, Westmeath and Pembroke, County Renfrew, Ont., mileage 67 to 83.45 from Ottawa.

15800—January 12—Authorizing City of Toronto to maintain wires across C.P.R. and G.T.R. and C.P.R. Tel. Co., also G.N.W. Tel. Co., at Queen Street, Toronto, Ont. Rescinding Order 13817, May 31, 1911.

15801—January 11—On Mond Nickel Co., Ltd., application authorizing C.P.R. to construct a public crossing at mileage 70.06 of its Cartier Subdivision, Ontario.

15802—January 11—Authorizing Canadian Copper Co. to construct spur across Algoma Eastern Ry. at grade and C.P.R. by overhead crossing, interlocking semaphores to be installed.

15803—January 15—Relieving C.P.R. from erecting and maintaining fences, cattle guards on Atlantic Division, between Woodstock and Andover, N.B.

15804—January 15—15805—January 16—Issuing certificate of correction to G.T.P.B.L. Co. correcting errors in locations of Biggar-Calgary Branch and Regina-Moosejaw Branch.

15806—December 21—Directing that G.T.R. install improved type of electric bell at Edward Street, Prescott, Ont., 20 per cent. from Railway Grade Crossing Fund.

15807—November 27—Authorizing C.N.O. Ry. to join with its line the tracks of Montreal Terminal Railway and C.N.Q. Ry. near Montreal, Que.

15808—November 17—Striking out words "at Vickers Street" in Order 15655 of December 20, 1911, City of Fort William and C.N.R. crossing.

15809—January 17—Authorizing C.N.R. Ry. to construct spur in town of Neepawa, Man.

15810—January 4—Dismissing application of Sanitaris, Ltd., of Arnprior, Ont., re express classification on returned empties.

15811—January 9—Authorizing C.P.R. to take certain lands in City of Toronto, and construct branch line to cross G.T.R. and join tracks used in common with G.T.R., also to cross Toronto Railway at Junction of Spadina Avenue and Front Street.

15812—January 18—Authorizing C.P.R. (Credit Valley Ry.) to construct spur into premises of Stone Fertilizer Co., Twp. of North Oxford, County of Oxford, Ont.

15813—January 16—15814—January 18—Approving plans of drain known as "A. Gilbert Drain" along right of way of M.C. Ry. to be constructed by Twp. of Southwold, Ont.; also plans and character of Chauvin Drain, under G.T.R. in Twp. of Tilbury North, Ont.

An Engineering Weekly

THE DESTRUCTION OF HOUSE REFUSE BY INCINERATION.

By RAY R. KNIGHT, A.M., Can. Soc. C.E., Etc.

The question of the sanitary disposition of house refuse is one which is exercising the minds of those in civic control of the large cities throughout this country at the present time, and it is a problem which demands the closest attention and most active administration in order to lessen the rate of typhoid and other diseases.

The common house refuse dump is the germinating centre of the house fly, and the house fly is the most serious carrier of the germs of diseases such as typhoid, tuberculosis, infantile diarrhoea, etc.

To quote from a circular recently issued by the Department of Agriculture, Canada:

"House flies breed in such decaying and fermenting matter as kitchen refuse and garbage. . . . All such refuse should be burned or buried within a few days, but at once if possible. . . ."

The burying of refuse is a proposition which cannot be entertained by the larger cities, as large areas of ground would be necessary for this purpose, so that the city has to prepare for burning its refuse.

To effect this the incinerator or refuse destructor is requisitioned.

Before getting into the subject real of this article it will be necessary to define the term house refuse and to subdivide it so as to agree with the general practice in Canada.

The term "house refuse" is an "old country" one, including as it does the whole of the refuse from an inhabited dwelling, excepting faecal matter.

Strictly speaking such items as slaughter house offal, dead animals, street sweepings, trade refuse, and industrial wastes are not included.

In Canada, where American terms have become general, these matters are divided under three heads, viz.: Garbage, rubbish and ashes. These are generally held to include the following:

"Garbage" includes all refuse of an organic nature, consisting of food wastes or swill.

"Rubbish" includes all combustible matter, such as paper, wood, rags, leather and house sweepings, also glass, iron, crockery, and such like.

"Ashes" includes household fire, kitchen fire, and heating furnace ashes. (Factory, industrial or boiler ashes are not included.)

Items not included are faecal matter, slaughter house offal, dead animals, street sweepings, and sewage sludge.

The matters which come under the head of "garbage" are those which give rise to insanitary conditions. Rubbish and ashes do not offend in this respect, so that the question before the engineer is really the disposal of "garbage" by incineration. The first question to decide in the formation of a scheme for house refuse disposal is that of subdivision of the matter. Garbage has to be burnt, rubbish may either be burnt or dumped, and ashes may be required to assist in the combustion of the garbage or may be entirely dumped. Probably the best method to adopt is to burn all garbage and rubbish, and dump all ashes excepting a certain amount required for assistance in combustion. Such a plan would require the division of the receptacles at the house into two compartments, one for garbage and rubbish, the other for ashes.

The matter of division, however, becomes somewhat altered where power is to be developed at the incinerator plant, as in this instance it is essential to have the ashes incorporated with the garbage and rubbish. Whether the whole or only part of the ashes are required to produce high temperatures is a question which has no general solution, but which must be decided upon investigation. The fine ash dust is however of very little value as a fuel, so that it would be necessary to screen the ashes and use only the larger.

The incinerator plant which will be discussed in this article will include the boiler and its appurtenances for the production of power.

Having arrived at some conclusion (as definite as can be with regard to the changeable characteristics of the material to be dealt with) as to the necessary subdivision, the question of quantity has to be decided.

Canadian households produce far more house refuse than those in the "old country." This is probably due to the absence of open fires which would receive and destroy a good amount of waste and also to the fact that thrift is less practical here. Be the cause what it may, the quantities given in data furnished by English cities are of no use to the engineer designing a plant in Canada.

An instance of this may be cited. In England a town of 36,000 people produces about 66 to 75 cubic yards of refuse (garbage, rubbish and ashes) per day, whereas in Westmount, Que., the population is 18,000 (half the population) and the production is between 80 and 103 cubic yards per day. An average for the large American cities is 57.7 cubic yards per day for a population of 18,000. These comparisons are given not so much as guides for the engineer but to warn him that it is essential to ascertain the amount of refuse the town or city produces actually.

In spite of the fact that quantities of house refuse vary considerably as between different towns or cities, the general composition remains reasonably constant, so that data as to the calorific value can be applied (within certain limits) to the design of furnaces and boilers for generating certain powers.

It will be noticed that quantities of house refuse are given in cubic yards in this article. This is not general, but would seem to be the better method of measuring owing to the excessive variations in weight. It will be necessary, however, to reduce cubic yards to tons when the amount of power that can be generated has to be ascertained. For this purpose the following weights have been taken:

	Lbs. per cub. yd.
Garbage	1,250
Ashes	1,500
Rubbish	300

Refuse composed of 14 per cent. garbage; 56 per cent. of ashes, and 30 per cent. of rubbish by volume is assumed to weigh 1,100 lbs. per cubic yard.

The calorific value of house refuse, garbage, ashes and rubbish, is of course a variable quantity, but it is usually considered for estimating purposes that 1 lb. of refuse will evaporate one pound of water from and at 212 deg. F. One pound of good steam coal will evaporate 8 to 10 lbs. of water from and at 212 deg. F. The dominating principle, however, in the design of an incinerator plant is the complete destruction of everything, solid and gaseous, and not the production of power, and to do this a temperature of at least 1,250 deg. F. must be constantly maintained, as at this temperature it has been ascertained that gases are rendered innocuous. Higher temperatures, however, should be aimed at, and a temperature of at least 2,000 deg. F. should be maintained in the combustion flue. This, of course, has to be accomplished with the aid of forced draught. For many years the steam jet was used in connection with refuse destructor furnaces, air being forced by the steam through the fire bars, water gas effect being produced and two highly combustible gases evolved, viz., hydrogen and carbon monoxide. These gases assisted in raising the temperature. The air was admitted without being heated, which was a serious drawback when moist or wet refuse had to be dealt with.

It is the general practice now to use hot air blasts in destructor furnaces, the necessary power being provided either by positive blowers or fans. Steam in just sufficient quantity to preserve the fire bars should be used in the forced draught.

We have, therefore, in the design of an incinerator plant to burn the matters collected and dumped at the works, produce a high temperature so as to render all gases innocuous, and provide as much power as is consistent with good results from the aesthetic and health standpoint.

In order to accomplish this the following principles have to be incorporated:

Storage of Refuse at the Incinerator.—In view of providing power for electric lighting, or for heating buildings, it is necessary in order to produce power when it is required to store some part of the day's collection of refuse upon the premises.

Storage should be made in closed receptacles. One form which has been tried in England provides for the storage of refuse in "tubs," which are stored in tiers and conveyed by overhead gear to the furnaces when required, the tubs being sealed with lids to prevent the escape of noxious gases.

The usual method, however, for storage of refuse is in a wrought iron or steel hopper. In order to prevent gases, due to decomposition, escaping, and to prevent the access of flies to the contents of the hoppers, they should be covered with hinged lids, and I would go as far as to recommend that these lids be water-sealed.

Method of Introducing Refuse into the Furnace.—The hoppers for storing refuse are best located above the furnace in such a position that the contents can be raked into a "feeding hole" in the furnaces with the least possible trouble, and as expeditiously as possible, as the length of time the furnace remains open governs the temperature of the whole plant to a large extent. The longer cold air has means of access via the "feeding hole" the cooler will become that particular furnace, and being connected with others the cooling effect will be noticed there also.

Where power is not required and a "direct feed" type of furnace used the refuse is dumped directly from the cart into the furnace.

In either case the feeding hole should be provided with a water-sealed door, in order to prevent the escape of fumes from the furnace while burning is going on. The water seal troughs in connection with the doors are kept at a constant level by a ball cock feed cistern, so that water evaporated by the heat of the furnace is replaced. While feeding or tipping refuse is proceeding it is necessary to introduce a hopper to prevent matters lodging in the trough.

Drying Hearth.—Immediately below the "feeding hole" should be located the drying hearth, upon which the refuse which is to form the next charge should remain whilst the charge is burning on the grate. Refuse contains varying quantities of moisture. Garbage contains from 60 per cent. to 80 per cent. of water. The percentage amount of water in mixed garbage, ashes and rubbish will of course depend largely upon the amount of ashes and rubbish contained. In the green vegetable season when the proportion of ash is low, the amount of moisture would reach the higher figure, while in the winter probably the lower figure would represent the percentage.

It is impossible to entirely remove this moisture on the drying hearth by the general heat of the furnace, and that reflected by the reverberatory arch, in fact only a very small amount of moisture is removed in this way. In drying refuse, gases and offensive fumes are given off, so that it is essential that the furnace be so constructed that these gases and fumes are compelled to pass over the hottest part of the fires before they can gain access to the flues.

Grate.—General practice seems to favor a sloping grate, and I have no hesitation in saying that I consider a sloping grate far in advance of the horizontal type for incinerator furnaces. The slope assists pulling down the refuse from the drying hearth and also facilitates to a very large extent the "clinkering" operation.

The essential features in the design of the fire bars are the retention of as much of the fine particles of refuse as possible and the admission of the proper amount of blast equally distributed throughout the grate area.

The type of grate bar most favored is that in which cylindrical holes are formed at the surface with conical holes at the under side. This type of bar proves very efficient for incinerator furnaces.

The front of the grate is formed by a cast iron dead plate which is placed horizontally and forms a continuous grate to the clinkering door in the front of the furnace. This plate being "dead" the actual flame does not impinge upon the front clinkering door to such an extent as if the perforated bars were continued through to the front.

Ashpit and Blast Chamber.—Below the furnace is provided an ashpit which also forms the blast chamber. The ashpit should be hermetically sealed and a pressure of 1 inch to 1½ inches of water should be maintained while burning. The

hot air conduit and steam jets are arranged to discharge at the will of the operator into this pit. The mixture of steam and hot air that serves the best purpose in burning can be ascertained.

Clinkering and Pulling Down Doors.—The operation known as "clinkering" is that of clearing the furnace of a burnt charge. As soon as the whole charge is considered thoroughly burned through, it should be drawn out, and this is done in the following manner: The blast is shut off from the particular furnace to be clinkered, and the clinkering door is elevated. The firemen with slices, pokers and rakes with long handles pull out the burnt charge in the form of clinker into barrows or tip wagons, leaving only odds and ends of incandescent or red hot pieces on the grate. The clinkering door is then lowered, and the charge from the drying hearth pulled down upon the grate through the pulling down door with long handled rake. As soon as the new charge is evenly spread about, three or four inches thick, the blast is turned on and more refuse pulled down as the fire increases in brightness until the limit (about six or seven inches of clinker' is reached, when the furnace is clinkered again.

It is essential in the operators of an incinerator plant to "charge" and "clinker" the furnaces in a regular cycle, so that the hot gases from advanced fires assist in the combustion of the gases given off from a new charge burning up.

Reverberatory Arch.—The furnace is covered by a fire-brick arch which plays a similar part to the reverberatory arch in other furnaces. This arch can be kept at a very high temperature throughout with care and expeditious handling, and the less it is cooled in process of feeding and clinkering the quicker will the fire rekindle.

Type of Furnace.—The foregoing particulars have reference only to the unit furnace, which is capable of destroying 12 to 20 cubic yards per working day of 12 hours with a grate area of about 30 square feet. In order to burn the refuse of a town or city provision has to be made for a set of furnaces. The continuous furnace as separate from the separate "cell" type has proved itself far more economical in first cost and repairs, and is the type I would recommend. By a continuous furnace type is meant the arrangement of furnace units side by side with an opening at the side connecting one with the other, so that the gases from furnace No. 1 are discharged into furnace No. 2, and these form 1 and 2 combined into No. 3, and so on. Four furnaces connected in this manner would constitute the limit, and I am of opinion that three furnaces only should be so connected. By this means the heated gases of advanced fires will materially assist fires in a less advanced stage, if proper regard is had to a cycle of operation. In the "cell" type each cell has its own flue.

Combustion Chamber.—The gases from the furnaces are discharged into a combustion chamber. This chamber has no particular shape or design, but is simply a large enclosed flue where the gases intermingle and carry on further incineration which the furnaces have left incomplete. The temperature maintained in the combustion chamber is the index of efficient burning. There should never be a less temperature than 1,500 deg. F. in this chamber, and much better results will be obtained if the temperature is kept at 1,800 to 2,000 deg. F. In the winter such a temperature is easily maintained, but in the summer it is probably only the lower temperature that can be raised. The combustion chamber also acts as a dust pocket, and mattress, slaughter house offal and dead animal, burning chamber. A large door is provided, preferably at the top for the purpose of admitting these larger articles. A door about 3 ft. 9 ins. by 3 ft. is usually found large enough to take a horse. Two outlets from this chamber are provided, the one leading to the boiler, the other to the by-pass flue. Each of these outlets should be provided with a damper to regulate the direction of the hot gases.

Boiler.—A water tube boiler with the ordinary setting and with a bridge and baffles so arranged as to direct the gases through the spaces between the tubes is usually provided in connection with incinerator plants. It is essential that a grate be provided under the boiler so that steam can be raised by a coal fire to start up the works after shutting down or after Sundays or where the power is entirely depended upon, as a stand-by. Description of the boiler and its setting is superfluous here. Superheaters and economizers may be added.

Air Regenerator.—The gases after passing through the boiler are led to the air heater. The gases if by-passed also lead to this apparatus. In the regenerator which is usually a cast-iron or steam tube arrangement of pipes so arranged as to expose the maximum amount of surface to the gases, the air for working the blasts is heated. The air is drawn from the upper parts of the building so as to take any escaped fumes or smoke, by a fan or positive blower and discharged into the regenerator and led to a concrete conduit below the furnaces. Each furnace is provided with a valve for admission of the blast. The air should be heated to from 500° to 600° Fah.

Main Flue.—After leaving the regenerator the gases are discharged into the main flue which carries them to the base of the stack.

In the main flue a dust pocket should be introduced. A right angle turn at the base of the stack with an extended flue, the floor of which is depressed about 3 feet, will answer this purpose. A door should be fitted to this pocket, for the periodical removal of dust.

Stack or Tall Chimney.—The usual remarks for furnace chimneys apply here. A stack from 60 to 100 feet high lined with fire-brick up to 60 feet is sufficient. The height of the chimney largely depends upon the aesthetic side of the question. With a good quality of garbage and a well handled plant and not too much cooling of gases for power production, a 60 ft. shaft is sufficient, but having regard to the occasional lack of care and other matters, I would suggest 100 feet as the height. A damper should be provided at the base of the stack, and for test purposes a piece of wrought iron tube should be left in, connecting with the inside of the stack.

Flues Generally.—In all flues provision must be made for expansion and contraction of the firebrick linings. Test or "peep" holes should be built into the flues at intervals for observations.

Firebrick Work.—The furnaces should be constructed of firebrick throughout. The best quality of firebrick should be used, as the varying temperatures are a severe test. Poor quality bricks will crack and fall out. Arches should be formed with radiated bricks, the taper being formed in the length of the brick. Fine ground fireclay should be used for mortar with the addition of sodium silicate in proportion of 1 to 20 by volume. The addition of fine powdered glass in proportion of three of fireclay to one of glass by volume has proved very successful in furnace building. The glass forms a flux at high temperatures and attaches itself to the bricks. The life of furnace brickwork is extended materially in this way.

The combustion flue should have a lining of best quality firebrick 9 inches thick. The boiler and all flues should be lined with firebrick (not necessarily best quality) 4½ inches

thick. The firebrick linings must not be bonded with the ordinary brickwork.

Opinion is divided as to the utility of the air space between the firebrick lining and the outside brickwork. Cheaper and better work and a more stable result after working can be obtained without the cavity, and the loss of heat being so small as to be almost negligible it would appear that the cavity could be left out. I consider work with cavities and wire bonding with 9 inch firebrick work (which is essential) costs 25 per cent. more than ordinary work, with the lining built against the outside work.

Buck stays and ties must be used to hold the furnaces and combustion chamber together. The whole should be free to "breathe" and it is essential to keep the boiler setting free from the effect of movements of other parts of the plant or strains may be set up, and injury to the tubes brought about. The whole plant should be free to expand or "breathe" as it is called.

The Cost of Incinerator Plants, and Working.—For the purpose of preparing an estimate for the erection of a destructor plant the following figures may be useful as a guide. Care should be taken however to add for local conditions and diifficulties. The prices are considered at Toronto, Ontario.

1. Two grate furnace plant with flues, hopper storage, boiler, regenerator, and chimney, capable of burning 80 cubic yards of refuse (garbage, ashes and rubbish) per day of 24 hours with 100 horse power boiler with steam fitting, $17,500.

1. Three grate ditto to burn 120 cubic yards with 150 horse power boiler, $23,500.

1. Six grate ditto to burn 240 cubic yards with two 150 horse power boilers, $39,000.

In addition to the above, prices for land, buildings, drainage, water supply, engines, dynamos, etc., auxiliary coal fed boilers, approach roads, and elevator for horse and cart where levels require it must be included.

The building should provide space for the plant which in the case of a two grate plant would be about 19′ × 24′ × 30′ to eaves; three grate plant about, 25′ × 24′ × 30′ to eaves; six grate plant about, 80′ × 24′ × 30′ to eaves. There should in this building be a tipping platform, and a feeding platform. In addition a boiler house, an engine and generator house with appurtenances must be provided, also engine and fan room, bathroom, W.C. lavatory, urinal, office, store and mess room.

The total site for buildings and future extensions and clinker storage should be about 1 to 1½ acres.

The staff necessary for operating an incinerator plant apart from the generating station and auxiliary boilers for 24 hours in eight hour shifts is as follows:

Number of furnace units.	Superintendent.	Laborers on feeding platform.	Firemen clinkering fires.	Laborers removing clinker.	Laborers Cleaning and assisting in removing clinker.	Engineer for fan and engine and boiler (assisted by engineers in generating station).	Ant. of refuse burnt. Total per 24 hours.
2	1	2	2	1	1	1	80
3	1	2	3	1	1	1	120
6	1	4	6	2	2	1	240

This staff is based on the assumption that the greatest load on the plant is during eight hours from 5 p.m. to 1 a.m. and that during the remainder of the day the plant is running light. The costs of flue cleaning once a fortnight and boiler cleaning as often as is necessary, have to be added. Interest on capital, depreciation and repairs have to be included in the costs. I consider in good class work the furnaces will require renewal once in 4 years and the combustion flue once in 8 years. Odds and ends of patching will be required in the meantime. The location of an incinerator is a point which has to be left to the discretion of the engineer to do what is best under the circumstances. It may be well to point out though that a modern refuse destructor properly managed is free from any nuisance from the health standpoint. The aesthetic nuisance however has to be overcome and though a site may be good from its position, being central it is probably better to locate the works in a neighborhood where from its character the plant would not be objected to. The cost of land is also a prohibitive feature sometimes.

In a large city it will be found economical to divide the city area into subdivisions of about 3 mile radius and provide an incinerator for each area.

The cost of burning refuse without deducting for fuel saved at generating stations and including interest and principal on 30-year debentures will vary between 30 cents and 40 cents per yard cube.

CRACKED CONCRETE CHIMNEYS.

In a report dealing with the cracked concrete stack of an English manufacturing plant, Sanford E. Thompson discusses conditions and some possible remedies which are of interest to those manufacturers who are burdened with big stacks built on the unhappy principle of a dry-mixed concrete. In this particular case of the London chimney, the structure had been put up on the dry-mix plan that was in vogue some years ago. The lower third of the stack was of greater diameter than the upper portion, and in the region of the offset, and above it, there were many long vertical cracks. The internal temperature of the stack was pretty evenly maintained throughout the year by the usual operation of the power plant, and there was some leakage through the cracks from the outside. The main concern of the owners, however, was as to the stability of the stack.

Danger from shearing stresses was considered very remote, since such stresses would not reach a critical point until long vertical cracks had formed on opposite sides of the chimney; and even then, an adequate amount of horizontal reinforcement would prevent the disruption of the stack. Corrosion and consequent weakening of the reinforcing steel was considered the point of most danger, the probability of this being rather large in case of concrete mixed so dry that it did not make a perfect bond with the reinforcement. With wet-mixed concrete the reinforcing steel is usually covered with a film of cement which will for a long time prevent corrosion of the steel by gases and moisture making their way in through the cracks.

As to remedies, the placing of a fire-brick lining was considered undesirable; such a lining would protect the concrete of the stack to some extent against the heat, but as good concrete easily resists a steady temperature of 600 or 700 deg. F., there was no need of a lining on this score. Moreover, it was considered that the presence of the lining might be mischievous, through the new expansion strains which it might transmit to the concrete strucure.

Repair by placing a shell of new concrete on the outside of the stack was considered the best course to follow. It is possible in building such a reinforcing shell, to shut off all access of atmospheric gases and moisture to the reinforcing members of the original structure, and to use reinforcing steel in such a way as to make good the weaknesses that have developed in the original structure owing to cracks, or to a presumption of an insufficient bonding of the reinforcement due to too dry a mix.

REPORT OF ANNUAL MEETING OF CANADIAN SOCIETY OF CIVIL ENGINEERS.

(Continued from last week.)

Friday Morning's Session—January 26th, 1912. PRESIDENT C. H. RUST in the chair.

MR. TYE: It seems to me we are giving everybody an opportunity of discussing these reports. We are referring these reports back to the different branches for discussion, including this branch here, so that every member will have an opportunity of discussing it. The point is that you cannot discuss them here to-day. So we are giving you all a chance in this amendment of Mr. Duggan's to discuss them to your heart's desire—the Good Roads report and every other report.

MR. MARCEAU: I quite agree with Mr. Tye that these reports should be referred to the different branches for discussion and suggestions.

DR. GALBRAITH: Unfortunately for myself I did not hear Mr. Duggan's amendment very well. How is the vote on these reports to be decided?

MR. JOHN KENNEDY: While the action we have taken as regards these reports is a very good one in every respect, I have not a word to say about it, but what shall we do about the Senate matter? It has been before the Senate for some considerable time and can we do anything towards getting the bill held over or something of that sort, because the bill is very much the contrary of what I fancy the majority of engineers think to be practicable. Can we do anything in the matter? Can our council take any hand in the matter and ask that it should be held over? I am sorry I have not a proposition to make, but the case is a rather serious one, and something really ought to be done.

THE PRESIDENT: I quite agree with you, Mr. Kennedy, that it is a very drastic method, but some engineers, I believe, are rather in favor of it. I appeared personally before the Senate some two years ago, at their request, and I pointed out my opinion in connection with the matter, and I also called the attention of the City of Toronto Council to it, but they have not taken any action. In fact, a good many of the outside public generally, I think, approve of Senator Belcourt's resolution, but if the society of the whole should pass a resolution suggesting that the matter be postponed until we have had an opportunity of taking it up with the committee, it might probably be a good thing if we can do it. Mr. Chipman has been taking some interest in this matter and I would like to hear his views on it.

MR. CHIPMAN: I have read with great interest the report of the committee as they appeared in the transactions. I regret to say, however, that there are some inaccuracies in it which should not have gone to the public. With reference to the streams in the west, there was a remark made that typhoid fever was caused by the floods in the streams. Now, we all know, who have lived in that country, that typhoid fever is epidemic in many towns distant from those streams, and in those towns cited the typhoid epidemic was in sections of the city that were not served with the water supplied from the river at all.

With respect to the pollution of Lake Ontario, there is a contradictory report in that statement that Lake Ontario water is the purest on the face of the earth, and there is another statement to the effect that it is badly polluted. I don't think a report like that does any great credit to the society. Remarks of that kind, I think, should have been edited in some way by the committee before they were presented.

With respect to the city of Guelph, it is true that the city of Guelph was in trouble respecting its sewage disposal, but the facts were not all stated. The works were not properly conducted as all municipal works are at times, through the economy of the municipal council, the cause of the nuisance was due to another source altogether from the muncipality. Now, there is a greater nuisance there to-day —ten times greater from a brewery than there is from the sewage disposal works. The sewage disposal works are quite up-to-date at the present time—even enlargements have been made.

With respect to this report I think we should receive it but not adopt it, as was done last year. The chairman of the committee is not here. Mr. Kennedy and I are the only two of the committee who are present. I think we should be permitted to report again next year.

THE PRESIDENT: I want to get your ideas as to whether this meeting should take any action in regard to Senator Belcourt's bill. That is what I was referring to, which prohitits the discharge of sewage of all kinds into any body of fresh water. Mr. Kennedy suggested that the society should take some action in the matter.

MR. CHIPMAN: I don't think at the present stage we should take any action in a matter of this kind. We are all studying these problems, and I do not think there would be anything gained by taking any action in the matter at the present time.

MR. TYE: I think it would be well for the society to take some action in the matter. I think it would be well if we appointed a committee to deal with the subject, if it is necessary to appear before the Senate and guide their legislation and help them. I think that the Senate would be quite willing and in fact glad to have the services of a committee from this society. This committee should be composed of men like Mr. Chipman, who are authorities on the subject, and who could help the Senate, and I think it is part of our duty to help guide legislation on such an important subject. Our committee composed of the proper men would certainly know more about it than the members of the Senate, and I beg to move that a committee be appointed to consist of Mr. Chipman, Mr. Kennedy and Mr. Lea, to deal with this subject before the Senate, and that their expenses be paid by the society.

MR. ST. GEORGE: You would not wish the society to get the Senate to withdraw the bill for the present. You see, they have had it so many years before them now. If the society do anything to hamper them in passing legislation, they might give time to these different smaller municipalities, but it might not be advisable to stop the bill. The committee might give advice to the Senate with reference to giving certain municipalities the necessary guidance.

MR. LEOFRED: You must not forget that the Provincial Governments are now spending much money and they are appointing officers every year with a special view of studying the question and obtaining legislation which would be adopted both by the Proincial and Dominion Governments. So I think it is scarcely wise for this society to interfere in the matter. The very best medical authorities in the country are working on the matter now, and are paid by the Provincial and Dominion Governments to study the

question, and I think we are not quite in our place to go before the Senate and interfere at this moment. We are not supposed to be such great authorities in sanitary matters, and in the analysis of bacteria as connected with the pollution of rivers and streams. I do not think we have the necessary knowledge in that matter to speak before the Senate, when there are so many eminent medical men, and chemists studying the question, to improve the situation. I do not see, for my part, what the civil engineers would have to gain by adopting such legislation as would prevent cities and towns from making an outlet for their sewage system into any river. There is still a great deal of controversy on the matter, and just now the cities and towns have not got the means to exactly satisfy the provisions of this bill.

MR. ST. GEORGE: I have great pleasure in seconding Mr. Tye's motion in regard to this committee. I feel confident that the society can leave it in the hands of the men named.

MR. JAMIESON: I thoroughy agree with Mr. Tye's motion, and that it is in the right line, namely, to put this committee at the disposal of the Senate to give them advice in the matter.

MR. KEEFER: I think, Mr. President, that it is a very excellent suggestion of Mr. Tye's to have an advisory committee, and that this society should show its willingness to co-operate with the government and assist them to prevent the pollution of our rivers and streams, because, of course, that is a very serious and important matter. The only question is the manner of doing it.

THE PRESIDENT: You have heard the resolution. What is your pleasure, gentlemen?

MR. JOHN KENNEDY: It seems to me the committee is a little small.

THE PRESIDENT: I would suggest that Mr. Tye be added to that committee.

MR. CHIPMAN: I wish to put myself right before the society, before this resolution is passed. I do not wish you to understand that I oppose or was not in sympathy with Senator Belcourt's bill, but simply that I did not think we should pass any resolution advocating the passing of that bill at the present time. I am quite in sympathy in assisting him in every way, and I think there are no men in the Dominion better qualified or in a better position to assist the government than we are.

MR. TYE: I did not mean by my resolution that we should appoint this committee and bind its hands, but I meant to leave it entirely in their hands to do entirely as they thought best under the circumstances as they find them.

THE PRESIDENT: Is it your pleasure that this motion should carry?

Carried.

THE PRESIDENT: There is a letter here from Mr. Forrester. Mr. Forrester sends a letter on steel pipes.

THE SECRETARY: I wrote to Mr. Forrester and suggested that he appear at the annual meeting, and he said he could not do so.

(The letter is referred to the incoming council.)

THE SECRETARY: I have here a letter from Mr. McIntyre.

THE SECRETARY: I have a letter here from Mr. P. M. Sauder, who writes to submit a resolution.

MR. JOHN KENNEDY: It seems to me this should be referred to the Conservation Committee.

MR. MITCHELL: I move that this should be submitted to the Committee on Conservation.

Carried.

THE PRESIDENT: There is a resolution here by Mr. Leofred.

THE SECRETARY: It has been moved by Mr. Leofred, seconded by Mr. Skaife, that the council take steps so that members of the Canadian Society of Civil Engineers be exempted to serve as jurors in the courts of justice of the Province of Quebec.

MR. HOLGATE: I think it would be rather trying to ask our council to assist us to escape our duties as citizens, and try to avoid matters of this kind. I do not think the society should take this matter into serious consideration.

MR. LEOFRED: It seems to me we should take some action in this matter, because all professional men practically are exempted from serving as jurors. The land surveyors are exempt, and I believe even dentists are exempt, and therefore I think engineers should be exempted.

MR. HOLGATE: If all juries were composed of engineers, I think we would have much better decisions.

THE PRESIDENT: Is this a Provincial matter or a Dominion matter?

VOICES: It is a Provincial matter.

THE PRESIDENT: Well, it seems to me we should let the Quebec branch deal with this matter.

MR. ST. GEORGE: I move with the approval of the annual meeting that this motion be referred to the local branch of Quebec as it is a provincial matter and they can do as they like about it.

MR. PARENT: Mr. Chairman, if this matter is to be submitted to the Quebec Branch, will we have the sympathy of this society? It is not only necessary that we have the approval of the society, but that we have its sympathy.

MR. TYE: I am very much in sympathy with what Mr. Holgate said. I don't think we should set an example of trying to shirk our duty, as citizens. I think the standard of juries should be raised, and not debased.

THE PRESIDENT: What is your pleasure, gentlemen?

(On a standing vote the president declared the motion lost.)

THE PRESIDENT: The next order of business is the reception of the reports of the scrutineers.

MR. MACKENZIE: May I ask a question?

THE PRESIDENT: Certainly.

MR. MACKENZIE: Is there any committee in existence now under which this subject would probably come—the disintegration of concrete surfaces in the intertidal space in sea water? If not, then I think the time has come when we should have a committee who would look especially into this matter. It is a fact with which we are not all acquainted, and there may be some difference of opinion upon it.

MR. JAMIESON: I think our committee on cement and concrete specifications have power to deal with this matter, and we have accummulated a large amount of data and information on this subject, but we have not yet been able to get sufficient definite information to make any report on it.

MR. JOHN KENNEDY: I agree with Mr. Mackenzie that it is a subject of the very greatest importance, and if that committee is not competent to deal with it—I mean if it is not within its powers—then some committee ought to be appointed.

MR. MACKENZIE: I think there is not any more important matter in the engineering profession in this country than this very subject, and the committee, I believe, must have had that power for some years, and so far as I can find out not very much has been done of a nature that would assist the engineers who are building such structures.

In the United States the engineers there—those who are working along the sea coast—have very definite ideas, so much so that they have abandoned the use of concrete in sea water to a large extent, and are using stone instead.

MR. JAMIESON: I may say in regard to the remarks of the last speaker that this is a comparatively new question, and that there are extensive tests being made in Germany

now, and the Scandinavian Committee composed of engineers and cement manufacturers, are now conducting a long-term test on this same subject, and also a great deal of work is being done in the United States. We must rely a good deal on that and get the result of all their tests, as far as possible, which we have been doing, and I think I have got all the data on that subject to date. By next year we will be able to do something definite.

MR. MACKENZIE: I beg to say that there is data scattered over this country which has not been collected; there is data scattered over this country which can be seen and the results noted. So far as I know, it has not been as yet.

MR. LEOFRED: I move that Mr. Mackenzie be added to the committee of the study and effect of sea water on cement work.

MR. JAMIESON: The committee already has power to add to its numbers, but we would be very glad to add Mr. Mackenzie to that committee.

THE PRESIDENT: The next order of business is the reception of reports of scrutineers on by-laws.

THE PRESIDENT: The next order of business is the report of the ballot for the election of members.

THE SECRETARY: I want to call the attention of the meeting to a little informality in regard to this. Mr. McAllister, who acted as the chairman of this committee, was not elected as the chairman. The gentleman who was elected did not report, and perhaps the society was out of session before it was noted that the chairman was not attending to business. A substitute had to be got for him, and Mr. McAllister acted as substitute. Perhaps the meeting would confirm the appointment of Mr. McAllister.

Carried.

THE PRESIDENT: I have much pleasure in declaring these gentlemen elected for the coming year, and I would ask the new president, Mr. Tye, to take the chair.

(The new president, Mr. Tye, here took the chair, amidst applause.)

MR. TYE: Gentlemen, I wish to thank you very much for your kind reception. I can only hope that you will be as well pleased when the year is over. (Applause.)

THE SECRETARY: Mr. President, the matter of the election of a Nominating Committee is one that is always dealt with under the by-laws by this meeting, and the mode of procedure under the by-laws is suggested by council. The mode of procedure which the council has adopted for the last two years is to request the branches to suggest two names at least for each office, and the annual meeting selects that one which commends itself. That provides for districts 3, 4, 5, 6, and 7. The recommendation with regard to district No. 1, which is the headquarters, has been made during the last two years by the local members of the council. Recommendation has also been made by the same local members of the council for district No. 2, which is the lower provinces and in which there is no branch. I have recommendations under that method for all the districts except the Quebec Branch No. 3, I understand that representatives of the Quebec Branch are prepared to make a nomination.

For District No. 1 I have one name only, that of J. L. Allan. For District No. 2 I have the nomination of Mr. R. S. Lee. For District No. 4, Mr. James White. The Ottawa branch sent only one name. For District No. 5 I think Mr. Haultain is prepared to make a nomination. He verbally gave me the name of Mr. T. C. Irving, Jr. For District No. 6 Mr. Frank Lea and Mr. E. P. Fetherstonhaugh. For District No. 7 Mr. J. C. Kennedy, Mr. E. C. Cartwright and Mr. H. L. Deutcher.

THE PRESIDENT: Is it your pleasure that you make any additional nomination to District No. 1?

MR. JAMIESON: Is it in order now to discuss this question? This does not seem a satisfactory way of proceeding, and it does not seem to give satisfactory results inasmuch as there has not been the full number nominated. Why not adopt the procedure of the American Society, which is to send out a paper for suggestions from all the members in each of the districts, and whoever has the greatest number of votes is usually appointed?

THE SECRETARY: That is done, Mr. Jamieson.

MR. JAMIESON: Well, over on the other side these papers are sent out and they prove very satisfactory. It gives every member of the society an opportunity to suggest for the Nominating Committee, and we must not lose sight of the fact that the Nominating Committee should be very carefully selected and every member of the society ought to be given a voice in the selection. It is essentially a point where they ought to have a say, because from that time on they do not have any say.

I would move, if it is in order to make a motion now, that this society adopt the same procedure as the American Society in regard to the Nominating Committee.

MR. SHANLY: I would like to say a word on the subject. If I remember rightly there was a time in this society when we used to send out circulars to all the members at the same time that the ballots went out, asking them for nominations for the Nominating Committee. The result, as I remember it, was if a man got half a dozen votes he might be elected. I remember I was proposed as a member of the Nominating Committee for one of the outlying districts, and there were, I suppose, a dozen other names submitted, each of them having one vote. I myself and one other member had two votes, and the tie was left to the decision of the annual meeting, and I was elected, I suppose, because I happened to be present. Therefore, I actually represented only two members of the society on that Nominating Committee. Now, if we send out ballots, as Mr. Jamieson suggests, it seems to me we will have the same trouble over again. We will have any number of names suggested and none of them will have an important majority.

MR. JAMIESON: Well, while that is true in the past, that is not necessarily true to-day. Conditions have very materially changed. It is, of course, up to the members themselves. Of course, if the members do not feel disposed to have a voice in the matter, very well and good, but this system is working well in the United States and they do get in larger returns. They get in a very large vote, and now the members are taking a great deal of interest in it, because it was satisfactory in the past. It was not the same procedure as I am proposing now, and the old, unsatisfactory system does not mean that the present one will be unsatisfactory.

THE PRESIDENT: Is it not more satisfactory to leave it to the branches and let them decide on whom they want?

MR. SHANLY: The trouble is we get a scattered vote. Each man votes independently.

MR. JAMIESON: Well, it will be representative, anyway.

MR. SHANLY: Under the present system the selection of the members nominated is left, as largely as possible, to the local branches. They are supposed to be in touch with their own members, and they can discuss the matter among themselves and send in a ballot which will represent the majority of their members. On the other hand, when each member votes independently you cannot get a majority.

MR. JAMIESON: That is exactly what I propose now.

THE PRESIDENT: And each district attends to their own part of the business themselves. Why should the council do that? Why not leave it to the branches? Then

the branches feel that they are represented, and that nobody else is interfering.

MR. JAMIESON: The American Society finds it very satisfactory, anyway.

MR. JOHN KENNEDY: Is there a branch in every district?

THE SECRETARY: Except at headquarters, and the lower provinces are without a branch. All the others are covered. In fact, in one district there are two branches.

MR. MYERS: I second the motion.

THE PRESIDENT: The business before this meeting now is the election of a representative for district No. 1.

MR. JAMIESON: Well, I asked if I was in order.

THE PRESIDENT: Well, I don't think it is in order at the present time. Has anybody else any other names to suggest?

THE SECRETARY: Mr. J. L. Allen is the representative for district No. 2. I am sorry there was an error.

THE PRESIDENT: Well, have you any other names to suggest for district No. 2, in addition to that of Mr. J. L. Allen? Is it your pleasure that Mr. J. L. Allen be the member for district No. 2?

Carried.

THE PRESIDENT: Now, for district No. 1, Mr. R. S. Lea.

Carried.

THE PRESIDENT: For district No. 3.

MR. PARENT: I am authorized by the Quebec branch to propose the name of Mr. E. A. Hoar.

Carried.

THE PRESIDENT: For district No. 4, Mr. James White has been suggested.

Carried.

THE PRESIDENT: For district No. 5?

MR. RUST: I move that Mr. T. C. Irving, Jr., be appointed.

Carried.

THE PRESIDENT: For the Manitoba district—district No. 6—the name of Mr. Frank Lea, and Mr. Fetherstonhaugh are suggested.

MR. LeGRAND: I beg to move that Mr. Frank Lea be appointed.

THE PRESIDENT: All in favor of Mr. Frank Lea please stand up.

Carried unanimously.

THE PRESIDENT: For district No. 7, the Vancouver branch, the names of Mr. J. C. Kennedy, Mr. C. E. Cartwright and Mr. H. L. Deutcher have been suggested.

THE SECRETARY: Mr. Cartwright is not eligible.

THE PRESIDENT: Very well, all in favor of Mr. J. C. Kennedy will please stand up.

Carried.

THE PRESIDENT: The only other business are votes of thanks to the railways of the Eastern Passenger Association, the Canadian Pacific Railway, the Montreal Tramways Company, the Dominion Bridge Company, the Canada Car Company, the McGill University and Doctor Barnes.

MR. MONSARRAT: I have very much pleasure in moving a hearty vote of thanks to be offered to these various companies and institutions and to Doctor Barnes.

MR. LeGRAND: I second the motion.

Carried unanimously, amidst applause.

MR. JAMIESON: Might I ask to put my motion that the Nominating Committee should be elected by ballot by the members at large from each district—that the members in each district should vote by ballot on their nominee for the Nominating Committee? In other words, that the secretary of each district should suggest the names.

THE PRESIDENT: Is not that an amendment to the by-laws?

MR. JAMIESON: Yes, I presume that would mean an amendment to the by-laws.

THE PRESIDENT: I am afraid that your motion is not in order at the moment. You will have to give notice of your motion before the first of October, so that it might be brought up at the next annual meeting.

MR. KEEFER: There is one motion I would like to make, and that I have very great pleasure in making, and that is, to thank the retiring officers of the society for the very able manner in which they have discharged their duties.

Carried, amidst applause.

MR. RUST: Mr. President, and gentlemen, on behalf of the retiring officers and myself, I wish to thank you very much for the kind way in which this vote has been proposed. We did the best we could, and that is about all I have to say.

MR. LINDSAY: I feel, as one of the visiting members, that I voice the sentiment of all of the visiting members in expressing our appreciation of the kindness extended to us by the Montreal members. As an Irishman, I suppose I wear my heart on my sleeve, but I am sure you have all made us very much at home here, and I assure you I appreciate it very much.

MR. LeGRAND: As a good Frenchman, I second the motion.

THE PRESIDENT: I declare the meeting adjourned.

THE DESIGN OF TALL CHIMNEYS.

(Continued from last issue.)

Prussian Government Rules.—In April, 1902, the Prussian Government issued regulations for the construction of chimney stacks. Square stacks to be designed for a wind pressure of 25½ lb. per square foot, with the centre of pressure at the centre of gravity of diametral vertical plane. Octagonal stacks 71 per cent. of the above pressure, and circular stacks 67 per cent.—Engineering Record.

Thickness of Brickwork.—Up to 150 ft. high, or 5 ft. inside diameter, the top length is generally one brick (9 in.) thick; above that height or diameter, the top length should be one and a half bricks thick, and the thickness should be increased by a 4½-in. set-off at every 20 ft. below the top. The outlet at top, and the throat or internal diameter at each set-off, should be of the calculated size to give the necessary area plus allowance for friction. Sometimes one hears it recommended that the top of the chimney should be contracted, to cause the expulsion of the gases at a greater velocity, and so to prevent down draught. It is said also that as the gases cool in their passage up the chimney they require a smaller sectional area to keep the velocity uniform. In general no attention is paid to either of these theories, and the section is kept as uniform as the other requirements will permit.

Batter.—If the diameter of the throat is kept uniform, and a 4½-in. set-off occurs at every 20 ft., the intermediate portions being of uniform thickness, a batter of 1 in 53.33 will be given, but the London County Council insist on a minimum batter of 1 in 48 = 2½ in. in 10 ft., and, besides that, it will be requisite in most cases to provide a firebrick lining for at least the bottom 15 ft. or 20 ft., having a thickness of 4½ in. and a clear space from the outer brickwork of 1½ in. to 2 in., necessitating a still greater batter.

Chimney Cap.—The chimney cap or cornice, by the London County Council rules, must not project more than the thickness of the brickwork upon which it rests. It may be of cast-iron castings, bolted together and filled with brick-

work, or of granite or other good weathering stone, the separate blocks being cramped together with galvanized iron cramps, or with an iron hoop sunk into the top and protected with cement, or of brickwork in cement.

Diameter at Base.—There is also an important rule of the London County Council which says: "The width of a shaft at the base, if square on plan, must be at least one-tenth, and if circular on plan, at least one-twelfth of the total height"

Firebrick Lining.—The firebrick lining must be entirely self-supporting, and have a clear space behind to allow for expansion and contraction independently of the main structure, which would be prevented if dirt and dust were to get behind it. It is therefore necessary to cover the top of the space by an over-sailing course of bricks built out from the inside of the main shaft, protecting the space, but allowing a clearance above the lining of ⅛ in. for every 5 ft. of its height, to permit of its expansion when heated. The average height of this lining is one-fifth height of shaft + 10 ft. A common height is 20 ft., and thickness 4½ in.; when of greater height it is necessary to make the lower part 9 in. thick. No air bricks should be inserted in the outer wall, as is sometimes done with the idea of cooling the air space, any such openings being very detrimental to the draught. The only possible inlet for air to the chimney shaft should be through the fire-bars or over the surface of the incandescent fuel.

The smoke inspectors of the London County Council have lately recommended openings into the chimney shafts near the bottom to reduce the smoke nuisance. The real effect is to dilute the smoke with air before it reaches the chimney top, so that it is not so black when expelled, but it does not reduce the actual amount of carbon emitted except so far as it tends to spoil the draught and so reduce the fuel consumption and boiler efficiency.

Stability.—Having drawn out the vertical section to suit the conditions, it will be essential to test the stability by calculation, but this is a somewhat complex matter and requires some preliminary data that will now be dealt with.

Materials and Weight.—The weight of each portion of the shaft—i.e., between each set-off—should be obtained separately so that the figures can be used singly or together. The weight will depend very much upon the material. Many chimney shafts are built of ordinary stock bricks and ground stone-lime mortar, and may be taken at 112 lb. per cubic foot. Others are built of solid machine-pressed bricks, and lias-lime mortar, and may be taken at 126 lb. per cubic foot. Some builders prefer perforated radial bricks and Portland cement mortar, weighing, say, about 100 lb. per cubic foot. Others consider that cement is too unyielding and that a shaft has greater ultimate stability if it sways lightly in a gale, which they fear the use of cement mortar might prevent. The bond usually adopted is one course of headers to four courses of stretchers, but sometimes tall chimneys are built in English bond, and occasionally in all headers.

The 450-ft. chimney at St. Rollox, Glasgow, is built in old English bond. The 300-ft. chimney at Johnson's Cement Works, Greenhithe, is built in Flemish bond. At Gosling's Cement Works, Northfleet, a 220-ft. chimney is built in stretching bond. At Barker's brick works, Worcester, the 160-ft. chimney is built with three stretchers, to one header. At the Surrey Commercial Docks, the 110-ft. chimney is constructed with all headers on the circular face. For the 100-ft. chimney at Farringdon Street Goods Station, Beart's patent perforated radiating bricks were used in the circular shaft, laid all headers on external face.

Hoop iron, galvanized or painted with cement wash, may be inserted at intervals of 5 ft. in height. The work should not be carried up too quickly, 3 ft. per day being quite sufficient unless the work is in cement.

The solid contents C of any portion of a circular shaft, having bottom outside diameter D in feet, top outside diameter d, uniform thickness t, and height h will be

$$C = \pi t h \left(\frac{D + d + \sqrt{Dd}}{3} - t \right)$$

and the weight will be C × weight of 1 cub. ft. of the material.

Safe Load on Material.—Assuming best workmanship and material, the maximum safe load may be taken as follows, being about 50 per cent. higher than would be allowed for live loads or inferior conditions.

	Tons per ft. super.
	Compression.
Granite	25
Portland and compact limestone	20
Hard York stone	15
Blue brick in cement	12
Stock brick in cement	10
Stock brick in lias mortar	8
Stock brick in grey lime mortar	6
Cement concrete 6 to 1	9
Deep clay (foundations not less than 10 ft. from surface), gravel and compact earth	3
Made ground rammed in layers	1½
	Tension.
Grey lime mortar (1 to 2)	1.0
Lias lime mortar (1 to 2)	1.5
Portland cement mortar (1 to 3)	2.0

Foundation.—It is important to note that a tall chimney should stand on an independent foundation, in order that the settlement or compression of the soil may be uniform. When a chimney is built close alongside a boiler-house, or within the four walls of a warehouse, it is sometimes placed on an extension of the other foundations and bonded in with other work, but this invariably leads to unequal settlement and subsequent cracks in the brickwork. It is evident that an ideal site would be on virgin soil of uniform character, preferably firm gravel, and not over old excavations or a filled-in water-course, or over old shaft workings, although all these positions have been adopted from carelessness or necessity.

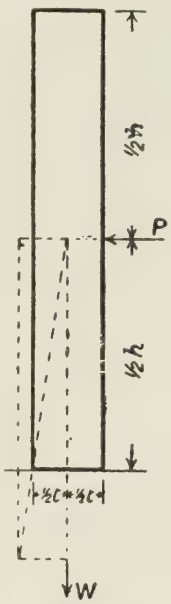

Fig. 6. Resultant of Thrust.

Principles of Stability.—The principles of stability can best be illustrated by taking a solid square brick pier, say 3 ft. square and 30 ft. high, weighing 1 cwt. per cubic foot. The total weight will be $3 \times 3 \times 30 \times 1 = 270$ cwt., the area of base $3 \times 3 = 9$ sq. ft., the mean pressure on base $\frac{270}{s} = 30$ cwt. per square foot. The resultant of the weight of all the parts passes vertically through the centre of gravity of the mass and cuts the centre of the base. If the wind be assumed to blow horizontally against one side the effect will be collected at the centre of the face and act with a leverage of half the height, as shown in Fig. 6, and the resultant of the two forces P and W will gradually approach the outer edge of the base as the wind pressure increases. Assuming that the pier could overturn on the outer edge as a fulcrum, without crushing, we have a case of simple leverage,

$W \times \frac{1}{2}t = P \times \frac{1}{2}h$, or $P = W\frac{t}{h} = 270 \times \frac{3}{30} = 27$ cwt., and

as P is made up of $3 \times 30 \times p$, we have $p = \frac{27}{3 \times 30} = 0.3$ cwt.

or 33.6 lb. per square foot.

Graphically the resultant will pass through the extremity of the base, as shown by dotted lines. Now, this is simple, but it is not true; the brickwork on the extreme edge would crush, and the pier would therefore overturn with a somewhat lower pressure. In practice we do not want our structures to overturn, and in order that they shall be safe when first built, we cannot allow any tensile stress on the inner edge. We therefore want to find what position the resultant must occupy for the pressure on inner edge to be reduced to zero. It will be observed that the wind, being a horizontal force, cannot add anything to the vertical force due to the weight of the structure, but it can increase the intensity of the pressure on a part of the base by forcing the resultant over towards one side and so altering the distribution. While the resultant is in the centre of base the pressure is uniform, as shown by the ordinates in Fig. 7, and as the resultant travels over to one side the pressure in-

Fig. 7. Fig. 8. Fig. 9.

Resultant of Thrust: Reaction According to Position of Resultant.

creases at one edge and diminishes at the other, as in Fig. 8, until finally the ordinates form a triangle, as in Fig. 9. This occurs in a rectangular base when the resultant falls at the extremity of the middle third, and is the origin of all false notions with regard to the efficacy of the middle third. The resultant falling within the middle third means no more than that the pressure then does not fall below zero on the inner edge; there is no guarantee that it may not be exceeding the safe load on the outer edge. On the other hand, there are many cases where the resultant falls beyond the middle third, and the structure is still only loaded within safe limits. In each of these examples the area of the shaded part, representing the forces of reaction, will be found equal, and it follows as a necessity that the maximum pressure indicated by the triangular Fig. 9 is double that shown by the parallelogram Fig. 7. In order to find the wind pressure to limit the resultant to this position we have to consider the altered leverage of the resistance; the weight of wall acting through its centre of gravity, Fig. 10, has now only a distance of $\frac{1}{6}t$ to the resultant, or centre of reaction, which is the virtual fulcrum; we therefore have the equation.

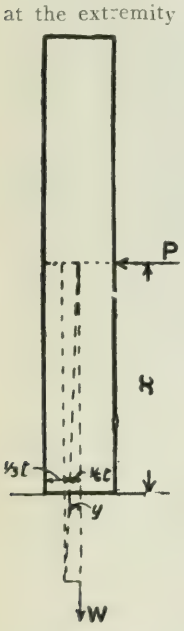

Fig. 10. **Resultant of Thrust.**

$W \times \frac{1}{6}t = P \times \frac{1}{2}h$ whence $P = \frac{W \times \frac{1}{6}t}{\frac{1}{2}h} = \frac{Wt}{3h} = \frac{270 \times 3}{3 \times 30} = 9$

cwt., and $p = \frac{9}{3 \times 30} = 0.1$ cwt. $= 11.2$ lb. per square foot.

as the maximum wind pressure instead of 33.6 lb., as found for simple overturning. This will produce a maximum intensity of pressure upon the base of $30 \times 2 = 60$ cwt. $= 3$ tons per square foot, which is below the safe limit, but we cannot increase it without reducing the pressure below zero on the inner edge, and although this might under certain circumstances be permissible, it is not generally considered desirable in the case of tall chimneys.

It will be well to use this illustration of a solid pier a little longer while we consider another point. Referring to the last figure, we can put the result another way. Making a plan of the base, as in Fig. 11, we can draw a triangle inside as shown by the ordinates, or shading lines, and if the base of the triangle represent the maximum pressure, then the ordinates show how the pressure reduces towards the inner edge. But we may look at it from another point of view, by assuming all the energy of resistance to be taken up by the particles within the triangle, so that they are all exerting the same pressure, while those outside the triangle are exerting none. This would give the same result, and it

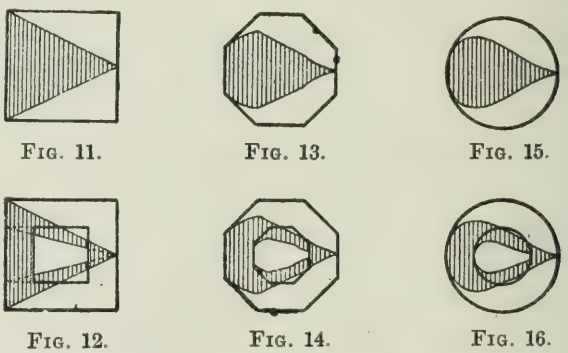

Fig. 11. Fig. 13. Fig. 15.

Fig. 12. Fig. 14. Fig. 16.

Resistance Areas of Different Sections.

explains better what is meant by resistance of area. The centre of gravity of the shaded triangle is the centre of effort of the resistance.

Application to Chimney Shafts.—The reason so much time has been spent over the plain brick pier is that we shall be able to deal with complex chimney shafts the more readily. Nearly all the different forms of bed joints can be reduced to a few simple diagrams. These are collected together in Figs. 11 to 16, the shaded part being the resistance area, or measure of effective resistance, of each. Another form of section may occasionally be found—viz., square, with two buttresses on each face—the resistance area of which would be found in a similar manner to the preceding, and the centre of gravity would be found experimentally by cutting out the area in drawing paper and suspending it from two points. These shaded portions have been described as resistance areas, although they correspond exactly with the inertia areas for a neutral axis coinciding with one edge. The reason is that in calculation account is taken of the actual conditions—viz., a uniformly distributed load, and a bending moment producing compression on one side and tension on the other side of a neutral axis passing through the centre of gravity of the section.

General Formula for Stability.—The general formula for a structure subject to a direct stress, and also to a bending moment is

$$K = m + \frac{M}{Z} \qquad k = m - \frac{M}{Z}$$

where K = maximum intensity of pressure in tons per sq. ft.
k = minimum intensity of pressure in tons per sq. ft.
m = mean ditto, due to direct stress, tons per sq. ft.
M = bending moment in foot-tons.
Z = modulus of section in foot-units.

This applies to all cases where the stress on the inner edge is not reduced below zero, and to such other cases as permit of a tensile stress.

d = deviation of centre of pressure when pressure becomes zero at opposite edge.

A = area of bed joint.

then $d = \frac{Z}{A}$

Also let—

W = superincumbent weight in tons.

A = area of section in square feet.

l = distance from resultant to edge of section in feet.

D = outside diameter or width in feet.

d = inner diameter or width in feet.

Then for solid square, Fig. 11—

$A = D^2$, $l = \frac{1}{3}D$, $Z = \frac{1}{6}D^3$

for hollow square, Fig. 12—

$A = D^2 - d^2$, $l = \frac{2D^2 - D^2}{6D}$, $Z = \frac{D^4 - d^4}{6D}$

for solid octagonal, Fig. 13—

$A = 2(\sqrt{2}-2)D^2$, $l = \frac{3}{8}D$, $Z = \frac{\sqrt{2}-1}{4}D^3$

for hollow octagonal, Fig. 14—

$A = (2\sqrt{2}-2)(D^2-d^2)$, $l = \frac{3}{8} \times \frac{D^2-d^2}{D}$, $Z = \frac{\sqrt{2}-1}{4} \times \frac{D^4-d^4}{D}$

for solid circular, Fig. 15—

$A = \frac{\pi}{4}D^2$, $l = \frac{3}{8}D$, $Z = \frac{\pi}{32}D^3$

for hollow circular, Fig. 16—

$A = \frac{\pi}{4}(D^2-d^2)$, $l = \frac{3}{8}\frac{D^2-d^2}{D}$, $Z = \frac{\pi}{32}\frac{D^4-d^4}{D}$

and if A be made use of to find Z,

Z = for solid square ..... $A \times \frac{1}{6}D$

" hollow square ..... $A \times \frac{1}{6}\frac{D^2-d^2}{D}$

" solid octagonal ..... $A \times \frac{3}{8}D$

" hollow octagonal ..... $A \times \frac{1}{8}\frac{D^2-d^2}{D}$

" solid circular ..... $A \times \frac{1}{8}D$

" hollow circular ..... $A \times \frac{1}{8}\frac{D^2-d^2}{D}$

It will be found that—

	Square.	Octagonal.	Circular.
l = for solid section	$\frac{1}{3}$D	$\frac{3}{8}$D	$\frac{3}{8}$D
" average hollow	$\frac{1}{4}$D	$\frac{1}{3}$D	$\frac{1}{3}$D
" infinitely thin	$\frac{1}{6}$D	$\frac{1}{4}$D	$\frac{1}{4}$D

and many designers are satisfied with these approximations, but for important work the exact distance should be obtained graphically or by exact calculation.

Ascertaining Stability.—Now the stability can be worked out from these diagrams and formulæ in two ways. Taking the 3-ft. brick pier as an example of a solid, square-bed joint, $Px = Wy$, but $y = \frac{1}{2}D - l = \frac{1}{2}D - \frac{1}{3}D = \frac{1}{6}D$, and $x = \frac{1}{2}h$, $\therefore P = W \times \frac{\frac{1}{6}D}{\frac{1}{2}h} = \frac{W}{3} \times \frac{D}{h}$, &c., as already worked out, when p was found = 11.2 lb. per square foot, and K = 3 tons per square foot. And by the second method $m = \frac{W}{A} = \frac{270}{9}$ = 30 cwt. = 1.5 tons, $M = p \times h \times D \times \frac{1}{2}h \times coeff = 11.2 \times 30 \times 15 \times 1 = 15{,}120$ ft.-lb. = 6.75 ft.-tons.

$$Z = \frac{1}{6}D^3 = \frac{3^3}{6} = \frac{27}{6} = 4.5 \text{ ft. units.}$$

$$K = m + \frac{M}{Z} = 1.5 + \frac{6.75}{4.5} = 3 \text{ tons per square foot as}$$

before.

In practice it will generally be necessary to work the other way round, and to make allowance for the taper of the portion under consideration, the stability of a chimney being usually measured by the maximum safe wind pressure. We know the maximum pressure on the bed joint will be twice the mean pressure, $K = \frac{W}{A} \times 2$, then the area must be such that K does not overstep the limits previously laid down by the tables of safe loads on materials.

(To be continued.)

STRENGTH VALUES FOR STRUCTURAL TIMBERS.*

By McGarvey Cliver, Director Forest Products Laboratory.

This circular brings together in condensed form the average strength values resulting from a large number of tests made by the Forest Service on the principal structural timbers of the United States. These results are more completely discussed in other publications of the Service, a list of which is given at the end of this circular, while most of them have also been furnished to the American Railway Engineering & Maintenance of Way Association and to various committees charged with the revision of the building laws of different cities. Their publication in the present form makes them available for quick reference by engineers, architects, builders, and other users of structural timbers.

The tests were made at the laboratories of the Forest Service, in co-operation with the following universities: Purdue University, Yale Forest School, University of California, University of Oregon, University of Washington, University of Colorado, and University of Wisconsin.

The Yellow Pine Manufacturers' Association, the E. P. Burton Lumber Co., the Redwood Manufacturers' Association, Oregon & Washington Lumber Manufacturers' Association, and the Pacific Coast Lumber Manufacturers' Association furnished, without cost, much of the material upon which the tests were made. Tests upon treated timbers, poles, crossarms, round mine timbers, and other structural forms are now being carried on.

Results.—Tables 1 and 2 give the average results obtained from tests on green material, while Tables 3 and 4 give average results from tests on air-seasoned material. The small specimens, which were invariably 2 by 2 inches in cross section, were free from defects such as knots, checks, and cross grain; all other specimens were representative of material secured in the open market. The relation of stresses developed in different structural forms to those developed in the small clear specimens is shown for each factor in the column headed "Ratio to 2" x 2"." Tests to determine the mechanical properties of different species are often confined to small clear specimens. The ratios included in the tables may be applied to such results in order to approximate the

*From Circular 189 Forest Service, U.S. Forest Service.

strength of the species in structural sizes, and containing the defects usually encountered, when tests on such forms are not available.

A comparison of the results of tests on seasoned material with those from tests on green material, shows that, without exception, the strength of the 2 by 2-inch specimens is increased by lowering the moisture content, but that increase in strength of other sizes is much more erratic. Some specimens, in fact, show an apparent loss in strength.

NOTE.—Following is an explanation of the abbreviations used in the foregoing tables:
F. S. at E. L.=Fiber stress at elastic limit.
M. of E.=Modulus of elasticity.
M. of R.=Modulus of rupture.
Cr. str. at E. L.=Crushing strength at elastic limit.
Cr. str. at max. ld.=Crushing strength at maximum load.

due to seasoning. If structural timbers are seasoned slowly, in order to avoid excessive checking, there should be an increase in their strength. In the light of these facts it is not safe to base working stresses on results secured from any but green material. For a discussion of factors of safety and safe-working stresses for structural timbers, the reader is referred to the report of the committee on wooden bridges and trestles of the Railway Engineering & Maintenance of Way Association published in the Association Bulletin 107.

The Canadian Engineer

ESTABLISHED 1893.

ISSUED WEEKLY in the interests of the CIVIL, MECHANICAL, STRUCTURAL, ELECTRICAL, MARINE AND MINING ENGINEER, THE SURVEYOR, THE MANUFACTURER, AND THE CONTRACTOR.

Managing Director: JAMES J. SALMOND.
Managing Editor: T. H. HOGG, B.A.Sc.
Advertising Manager: A. E. JENNINGS.

THE EMPLOYMENT OF ENGINEERS.

At various times, in the columns of *The Canadian Engineer*, we have referred to the employment of engineers from outside Canada. In many cases our remarks have been challenged as being unfair to the outside engineer. Let us quietly and dispassionately look over the situation and see how matters stand.

In a recent address to the students in engineering in the University of Toronto, Mr. M. J. Patton, representing the Conservation Commission, stated that in gathering information and data from various sources for the compiling of the recently published "Reports on the Water Powers of Canada," those in charge of the work were surprised to observe that so large a proportion of plans for the hydro-electric development being carried on in Canada were prepared by foreign engineers. One of the students, in reply, said he hoped the Conservation Commission in their work would remember to conserve positions for the Canadian engineers, as it was becoming very difficult for the young graduate to obtain work along an engineering line. The above example, coming as it did from an official source, carries some weight, and we are constrained to ask, Why it is that our own consulting engineers are not doing this work?

One of the main objections to the employment of foreign engineers is the fact that a knowledge of local climatic conditions is essential to the success of engineering work. The design of hydro-electric installations, of sewage disposal works, and of many other departments of the engineering profession, are governed in a great measure by ice, snow and frost, and no man can do full justice to the work unless he is thoroughly acquainted and accustomed to the conditions. A consequence of this lack of knowledge is to be seen in the results of the recent installation of a central heating system for one of our large institutions of learning. This system was designed by a firm of consulting engineers from the United States, although the institution in question is government supported, and has on its list of engineering graduates dozens of men whose experience and training fit them for this work. This firm installed a gravity heating system against the opinion of many of their graduates, and the institution in question is now reaping the harvest in lack of heat and increased coal bills. Many similar instances might be quoted, but this particular one is rather flagrant. If the institutions which are turning out engineers will not use their own graduates, where can work be found for them?

We publish a letter this week from a Canadian, at present employed in the United States, who feels that we were unjust in our remarks a short time ago. The writer, however, does not appreciate our stand in the matter. There is certainly no objection to men from other countries coming to Canada and taking up their abode here. In fact, many of our engineers have done this very thing. They have, however, become Canadians. Likewise, many Canadians have left this country to take up work in other lands, and the writer of the letter mentioned is one of these. The engineers who come here to stay, and who come to take junior positions, will in turn become Canadians. On the other hand, it will be found that there is strong objection to foreign consulting engineers doing work in this country which can be done equally well by our own engineers.

The public bodies of the country should be the first to appreciate this principle and lend it their hearty support.

EDITORIAL COMMENT.

The series of articles on "Contracts for the Supply of Electric Power from the User's Point of View" is finished in this issue. We shall be glad to furnish the article in pamphlet form if there is sufficient demand from our readers.

* * * *

The old haunt of the student in vacation time has been cut off. The new regulations for fire rangers in Ontario have been issued by the Department of Lands, Forests and Mines, and in all the long list of rules the word "student" does not appear. The student in his intervals between study must find some other means of employment than canoeing and meandering through the northern wilds.

* * * *

The first of a series of articles on the "Principles of Specification Writing" is printed in this issue of *The Canadian Engineer*. When the series is complete we will publish the series in pamphlet form. The subject of specification writing is an exceedingly important one, and far too little attention is devoted to it. We are pleased to note that the Faculty of Applied Science and Engineering of he University of Toronto has taken the matter up, and Mr. C. R. Young, the author of this series in *The Engineer*, will deliver a short course on the subject to the students in engineering.

LETTER TO THE EDITOR.

The Editor:

Sir,—Many Canadian engineers engaged in their profession in the United States, like myself, temporarily or otherwise, will regret your ironical remarks on the appointment of a St. Paul man to the city commissionership of Moose Jaw.

It is to be hoped that many Canadian engineers at home will approve of the broadmindedness of the city of Moose Jaw in selecting the man who was considered to be best fitted for the position, irrespective of nationality.

The West has welcomed farmers and others from the United States to aid in building up the country. The engineer has been defined as a man who makes two blades of grass grow where only one grew before. Why is it not as consistent to select an engineer from the United States to help build up a city as it is to import American farmers to develop the country?

DONALD F. McLEOD, City Engineer.
Ithaca, N.Y.

IMPORTANT NATIONAL QUESTIONS DISCUSSED

Many unusually important points were brought to the attention of the new council of the Toronto Board of Trade on Thursday by Mr. G. T. Somers, the president. After quoting statistics respecting Toronto's remarkable growth, Mr. Somers urged the initiation of an actual movement for the immediate settlement and development of Northern Ontario. He showed that the continued industrial and business growth of Toronto and Southern Ontario would depend to some extent on the North, especially in view of the manufacturing tendencies in Western Canada.

The president also referred to the great loss of life and the large number of accidents in Toronto last year and quoted a recent article of The Monetary Times which told that in six years, 36,710 people have been killed or injured in Canada in accidents on steam and electric railways, at fires, and by industrial accidents. This is at the rate of 9,177 per annum. In other words, every day during that period 25 persons have been killed or injured. The Board, he said, could help to minimize this appalling record, so far as Toronto is concerned, by assisting to improve traffic rules, automobile speed regulations, the abolition of level street railway crossings in congested areas, and in many other ways easily apparent.

It was hoped, continued Mr. Somers, that early and serious consideration would be given by the Dominion Government to the enlargement of the Welland Canal. In this connection, he suggested that in planning for the enlargement of the Welland Canal it might be well for the government engineers to consider the question of incidental power production. Great plans for the development of power plants on the St. Lawrence above Montreal indicated that the Cornwall and Soulanges Canals may be cut out of the system and replaced by deep waterways created in connection with the building of power dams. If the expectations of the promoters of these and kindred projects were realized, the deepening of the St. Lawrence channels might be a source of profit to the people of Canada instead of a heavy bill of expense. While the proximity of Niagara and its great power plants must lessen the immediate value of power developed in connection with the enlargement of the Welland Canal, it must not be forgotten that the operation of the canal would require the pouring of a large volume of the waters of Lake Erie over the escarpment at Thorold. Should there be any truth in the rumor that six or seven locks of great depth and capacity are to be substituted for the large number of small locks on the present canal, the waste water from these locks might well become an important source of revenue to the government if utilized for power production.

Mr. Somers suggested the study of the lake levels by the Associated Boards of Trade, stating that a reduction of two or three feet in harbor depth is a serious calamity. Many excellent suggestions were also made regarding the good roads movement and these, we expect, will receive the attention of the Dominion Government and other authorities.

It was pleasing to note that Mr. Somers recommended earnest attention to the question of fire waste, and advised the support of the Board of Trade to the appointment of a provincial fire marshal. Too few public men and bodies are giving their thought to Canada's appalling record of fire losses.

The strengthening of the pure food and drug laws, the bringing of radial railways to the heart of Toronto, the appointment of a properly qualified industrial commissioner for Toronto, the present conservative valuation of Toronto real estate, were other matters discussed by the president, who also reminded his hearers that the advice of the Royal Commission on technical education is eagerly awaited. It is hoped that the membership of the Board will be 3,000 by the end of the year.

In connection with the radials, Mr. Somers said there were remunerative opportunities awaiting the enterprise of market gardeners around Toronto. Only a comparatively small proportion of the garden produce consumed in Toronto is grown in the immediate neighborhood. Secretary Wilson, of the United States Department of Agriculture, the other day drew attention to the question of utilization of lands near large cities, so that their markets for foodstuffs could be supplied with home-grown products. Only recently 15,000 tons of potatoes reached New York from Scotland for New York City consumption.

THE PRINCIPLES OF SPECIFICATION AND AGREEMENT WRITING.

By C. R. Young, A.M. Can. Soc. C.E.*

(Registered in accordance with the Copyright Act.)

First Article.

INTRODUCTION.

Present Status of Specification Writing.

Probably no detail of engineering work is given less attention in proportion to its importance than the preparations of specifications and agreements. Most engineers regard the task as a piece of unavoidable drudgery to be met with rare stoicism and gone through as quickly as possible. Hence, in office vernacular, specifications are said to be "ground out," not "written." In addition, they must only too often be prepared in an absurdly small remnant of time left between the completion of the plans and the calling for tenders, or, indeed, even after the invitations to tender have been issued or the advertisements published. Little thought can thus be given to the foundation of specifications on fundamental principles, and although each new undertaking of the engineer or architect nearly always differs materially from any other upon which he has been engaged, necessitating perhaps some important departure from former practice, no attempt is generally made to prepare a specification fully comprehending all the new and changed conditions. Instead, an ample collection of old specifications is gathered together and from this one and that one clauses are chosen which appear to be adapted to the case in hand, and with the good offices of the scissors and the paste are jumbled together to form the new document. It is therefore not remarkable to find that litigation arising out of Construction Contracts is sufficiently frequent and protracted to elicit a great deal of popular comment unfavorable to the engineer or architect responsible for the work.

Necessity for Increased Care and Thoroughness.

The engineer's success and his reputation with the general public, upon which his ultimate success depends, alike demand greater care in the preparation of specifications and agreements. Nowhere is haste more productive of sinister results than in this work. There are occasions in the consideration of any engineering undertaking when only the general features are of importance and indeed when the widest and most general view possible of the entire project should be taken in order that it may seem as a whole in its true perspective and in proper relation to existing conditions. But when it comes to the preparation of specifications and agreements, the "promoter" attitude of mind must give way to the close and painstaking scrutiny of details. In this work clearness, definiteness and strictest accuracy in all particulars are of the utmost consequence. Such a result can be secured only by the exercise of care and thoroughness in the work. The slighting of details and the covering up of ignorance and lack of proper consideration of the subject by such expressions as "the work shall be done to the satisfaction of the engineer," while apparently effecting a present saving of time are almost certain to later entail a much greater loss of time to all concerned and perhaps considerable financial loss as well.

*Consulting Structural Engineer, 318 Continental Life Building, Toronto.

Scope of the Proposed Discussion.

In the hope that some assistance might be afforded to those who are interested in the improvement of the present character of specification and agreement writing, the writer proposes to discuss the principles of the subject in this and succeeding papers. What is said will not concern the merits of, or the desirability of specifying, any type of construction, design, detail or method, but, rather, the art or science of fully, accurately and unambiguously describing the features and details which already have been adopted. The method to be followed will therefore not be the quotation of a number of authoritative specifications from which the reader could select such portions as appeared to be adapted to his own work, but, instead, it is proposed to state and illustrate in so far as possible the **fundamental principles** upon which all specifications and agreements should be based. By a thorough understanding of these principles, and only by such means, is it possible for anyone to prepare satisfactory instruments of this kind.

Because of the limitations of available space it will be necessary to confine the present discussion to the commoner forms of construction contracts. While it is fully recognized that many things might profitably be said concerning the distinctive features of specifications and agreements for the various forms of "secured-cost" contracts, attention will be chiefly directed to the "unsecured-cost" contract, the one most commonly employed, and the one nearly always adopted in public works.

The Engineer's Limitations.

It is obvious, of course, that the engineer cannot safely dispense with the services of the solicitor, as a result of gaining some little acquaintance with the principles of contract law. No one with experience will dispute the old observation that "A man who is his own lawyer has a fool for a client." For most contracts, however, a lawyer is not consulted in any event, and if the engineer has some familiarity with the essentials of proper specifications and agreements, his work is likely to be much more satisfactorily performed than if he does not possess such information.

PRELIMINARIES TO THE CONTRACT.

Procedure of the Owner in Allotting the Work

When a person, company, municipal corporation or government, and which for brevity we may call the Owner, desires to carry out a piece of engineering construction, he, or it, procures the services of an engineer or architect specially skilled in the particular class of work under consideration and who in continuous consultation with the Owner develops designs and details conforming to the needs and purposes of his client. The latter not generally possessing the knowledge, experience, plant or organization essential to the successful and speedy prosecution of the actual work of construction prefers to delegate the risks and responsibilities incident to such a project to someone else especially qualified to undertake them, and at the same time, before commencing work, to ascertain with some accuracy the final cost and the time of completion. It is not in general desirable for him to entrust both the preparation of designs and the actual work of construction to

one person or firm, because on one hand, the engineer or architect is not likely to possess the special experience or organization required for the efficient performance of the work in the field, and on the other hand, most construction firms are not especially well qualified to advise the Owner concerning the more troublesome engineering or architectural features of the project. Further, the value of a check would be lost, if the Owner were to place his case wholly in the hands of one person. If the latter proved dishonest, the Owner might be grossly deceived with little risk of detection. Thus it has come to pass that the Owner commonly places the actual work of construction in the hands of a third party, called the Contractor, who supplies all materials, performs all labor, and delivers up to the Owner in a stated time the desired structure, work or article, complete and ready for use.

The Preparation of Plans, Specifications, and Agreements.

In order that the Contractor may know precisely what is required by the Owner, and also that the Owner may ensure his being supplied with what he agrees to pay for, the latter's engineer (or architect) prepares graphic or written statements of the work to be performed and of the business relations which the Owner proposes shall subsist between himself and the Contractor during the progress of the work. Those requirements which can best be shown graphically, such as dimensions, shape and size of parts or quantity and distribution of materials are preferably embodied in **plans**, while the quality of materials, workmanship and methods of construction lending themselves readily to written description are set forth in **specifications.** In the latter are also stated certain general relations, as of authority, which it is proposed shall govern the Owner and the Contractor or their representatives in the actual physical construction of the work. A formal **agreement** is also drawn up and attached to the specifications setting forth the general nature of the proposed arrangement between the parties, including the financial or other valuable consideration involved and to this it is expected that both the Contractor and the Owner will affix their signatures upon the award of the contract.

Because of the complexity and multiplicity of details in most constructional projects it is essential that everything affecting the extent or cost of the work should be clearly set down in writing or on plans before the award of the contract, not only for the information of the Contractor in making up his bid, but for the subsequent guidance of the Contractor, the Owner's inspector and all others having to do with the work. While oral agreements may be satisfactory for trifling pieces of work where the parties are both of unquestionable integrity, the uncertainty of memory and sometimes the willingness of one party to take an unfair advantage over the other demands that all the requirements of the Owner and all understandings between the Owner and the Contractor should be reduced to writing or shown on sketches or plans.

The Closing of the Contract.

Having entertained bids or proposals for the work up to a specified date, the Owner awards the contract upon the advice of his engineer, and the successful bidder is required to sign the agreement, specifications and plans which then collectively become the **Contract.** The agreement is sometimes termed "the contract," but since the specifications and plans are declared in the agreement to be a part of the contract, this practice is therefore manifestly erroneous.

THE COMPOSITION OF AN ENGINEERING CONTRACT.

Length and Amount of Detail.

The character of the work in hand is the most important factor in determining the length and amount of detail in an engineering contract. Where the work is simple or of small extent a letter from the Contractor to the Owner offering to supply all materials and perform all labor for a certain consideration may be sufficient. If the communication refers to a plan or sketch furnished by the Owner it should contain the Contractor's pledge to execute the work in accordance with such plan or sketch. On the other hand, the Contractor may himself submit a plan with his letter setting forth what he proposes to do for the compensation mentioned. The specifications are also of very brief character when the Owner purchases a machine, article or commodity covered by letters patent or which is subject to some degree of artificial or natural monopoly, and which is therefore produced in accordance with the Contractor's and not the Owner's ideas. Unless competition is very keen, manufacturers are not eager to supply machines or other articles to special plans and specifications prepared by the engineer, for this means changing the character of their product, methods and processes which had perhaps been arrived at and constituted shop standards after many years of experiment and observation. In some instances the process of manufacture and the materials employed are secret, and, since the purchaser could have no knowledge of these, they manifestly could form no part of the specifications. The purchaser therefore does not usually submit plans to the bidder in the case of machinery, patented appliances, and many other articles and commodities, but limits his specifications to a brief statement of the required performance or ability to meet certain specified tests.

Where the piece of construction is built in accordance with the engineer's, and not with the contractor's, ideas, such as railroads, canals, tunnels and often bridges and buildings, plans and specifications of an extensive character must be prepared, and the difficulty of framing a proper contract is considerably augmented. Added to the necessity of clearly specifying what is required in, and of, every part of the finished work is the need of ensuring that unfavorable natural or climatic conditions, difficulties of transportation or labor troubles, all of which greatly affect field operations, shall not preclude the attainment of the desired result. Although, in theory, it is only in the result that the Owner is interested, he must also reserve the right to prevent the Contractor from continuing in a course which is reasonably certain to culminate in failure. Many contingencies must therefore be provided for in work constructed to order in the field, and the specifications grow into many typewritten or printed pages. The agreement is also properly more detailed than that pertaining to the simpler classes of work already mentioned.

The length and fullness of the specifications will also depend on the nature of the arrangement with the Contractor. If the engineer prepares the complete designs and the Contractor is only required to construct the work at his shops or in the field in accordance with such designs, the specifications need only deal with construction. On the other hand, if the Contractor is re-

quired to prepare the designs and do the actual work of construction as well, the specifications must of necessity be much fuller than in the first case. Experience has shown that the latter method is objectionable on a number of grounds. In the first place it leaves the Contractor free to adopt many faulty features of design which for the sake of brevity could not all be expressly forbidden in the specifications, but which would have been rendered impossible by the engineer designing the work himself. Again, unless all contractors bid on the same design, viz., that of the engineer, those who have least to lose will submit low bids on questionable or flimsy designs of their own, which may inadvisedly be accepted by the Owner to his subsequent sorrow. This method also entails much trouble in case changes are desired, for unless the engineer has clearly shown by plans of his own exactly what he requires, the Contractor will generally contend that his own plans supply all that was called for in the specifications. Thus, it is desirable wherever possible to have bids based not only on specifications but on full detail drawings prepared by the engineer, rather than on the Contractor's design or even on general drawings prepared by the engineer.

Another feature of the arrangement between the Owner and the Contractor materially affecting the length and amount of detail of the contract is the manner in which the Contractor receives his profit. If the contract is a so-called "lump-sum" one, the amount of detail and the care and preparation of the necessary documents is much greater than for "secured-cost" contracts, such as those on a "cost-plus-a-percentage" and "cost-plus-a-fixed-sum" basis. On a "lump-sum" contract the Contractor naturally strives to reduce the cost to a minimum since the difference between his bid and the cost is all gain. Special care must therefore be taken in preparing the specifications to prevent the Contractor scamping the work in order to increase his own profit.

In accordance with the complexity of the work and the character of the contracting parties, construction contracts may thus be composed of agreements, specifications and plans in varying proportions. For all, there should be some form of agreement, although perhaps quite simple, since in this is disclosed the intention of the parties and the general basis on which the arrangement is made. Lacking such written statement, the settlement of disputes is often attended with great difficulty, as an attempt must be made to prove by oral evidence what might have been established by a few lines of writing.

AN ACTUAL SAVING OF WOODEN FORMS.

There are three general types of coal pockets in use today, the all-timber, the all-concrete, and the combination type of concrete and timber. A great many of the latter design have been erected according to plans of Monks & Johnson, architects and engineers, of Boston, who are able to reduce the cost of coal pockets considerably by using the forms for the reinforced concrete work in constructing a part of the wooden walls and bins of the coal pocket. The cost of all reinforced concrete coal pockets range from $6.00 to $7.50 per ton of capacity, but in the combination type, where the supports and the floors are of concrete but the walls are of timber, the cost is generally about $5.00 per ton of capacity, and this in no small part is due directly to the actual saving of the forms by incorporating them in the coal pocket itself.

AMERICAN SOCIETY OF ENGINEERING CONTRACTORS.

Annual Meeting, January 9, 1912.

The third annual meeting of the American Society of Engineering Contractors was held in New York City on the 9th day of January, 1912.

In the forenoon members of the society visited, in a body, the new Grand Central terminal, at the invitation of Mr. W. L. Morse, Terminal Engineer of the N.Y. Central & Hudson River R.R. Co. They were escorted by Mr. E. D. Sabine, first assistant terminal engineer; Mr. W. C. Goddard, terminal architect's engineer, and their assistants.

It is needless to say that great interest was evinced by the members who were fortunate enough to view the remarkable work accomplished and still going on, which work will result in probably the greatest railroad terminal in the world. Particular interest was manifested in the method of coating all the steel columns, beams, etc., in the lower level with cement. The mortar is applied directly through the "cement gun" by the agency of a blast of compressed air.

At the afternoon session, which was devoted to a business meeting, the address of the retiring president of the society, Mr. W. R. Harris, was read. Mr. Harris, who, for nearly one year, has been located in the Canadian Northwest at Regina and Saskatoon, Sask., was unable to be present. He stated that even in those distant provinces much interest is evinced regarding the work undertaken by this society, which is about to be manifested by the organization of branches.

We read and hear much these days relative to workmen's compensation for injuries sustained. Undoubtedly, many superficial observers show little interest in this question unless directly affected in legislation of this character with the result that many laws have been passed which, if enforced, will be bound to affect seriously contractors and, ultimately, the public. It goes without saying that every added expense saddled on the contractor through such laws is not going to be assumed by him, but must be paid by the owner, whether he be an individual or the public. This is simply a business proposition.

Mr. Harris related that during the last session of the local Parliament in Saskatoon a law was passed whereby all workmen, except farm laborers, are entitled to compensation for injuries, whether sustained through carelessness or not. This is class legislation of the worst kind, because the farmer, who employs the larger part of his force only a short time each year, is not affected, while the manufacturer and the contractor are liable. Furthermore, the law is unfair in its effect on the bids of various contractors. The man who is responsible and, therefore, is able to obtain liability insurance must pay the higher premiums caused by this Act, and, necessarily, must include such cost in his bid. On the other hand, the contractor who, because he is not financially responsible, or for some other reason, does not secure such insurance, would not have to figure on such an additional expense and is thereby able to reduce his bid accordingly.

The remedy is an organization like this society which, when necessary, will oppose reckless legislation and insure that, if general compensation statutes of this kind are deemed necessary, each man who employs labor shall be affected equally.

A point of interest to all engineers who have to specify tests for cement is one brought out by Mr. Harris. He stated that, under the present specifications, tests required for cement fail to provide the safeguards anticipated. For

instance, while the usual method of taking one barrel in every ten of a shipment as a sample of the material, the method of mixing the samples is not satisfactory. It is provided that, to determine the characteristics of a shipment, the individual samples may be mixed and the average tested. This may not be objectionable where the cement is used in massive concrete subject to compression only. In reinforced concrete, however, because comparatively thin members are used, this method should not be allowed.

The reasons given by Mr. Harris for his position are as follows:—

It is acknowledged that 80 per cent. good cement will carry 20 per cent. poor cement. If the average sample of a shipment shows only 20 per cent. bad material it is, according to standard specifications, allowable. However, the mixing which is done with the sample is, of course, not repeated with the bags of cement, since it would be impracticable to take a car load shipment, mix it and remeasure it to secure the proper proportion.

The result is that where mixing up a batch of concrete, the sacks used may contain as much as 50 per cent. bad cement, and just as likely as not this concrete may be placed in a portion of the structure where only the best material should be used.

Again, a shipment of cement may contain the products of different mills, cement which may be different in regard to setting time, fineness, etc. It is bad practice to use two brands of cement in the same concrete mixture, but if the products of several mills are placed in sacks of a common brand, it is impossible to tell by looking at the sack whether the contents of a car would run uniform or not, except by individual tests.

This question is of much importance to architects, engineers, contractors, and manufacturers of cement products. Mr. Harris recommended concerted action by this society with other technical societies to eliminate the foregoing defects of the present specifications.

After Mr. Harris' address was read the result of the election of officers was declared. The following officers were elected:—

President—Maj. C. E. Gillette, of Philadelphia, Pa.

1st Vice-President—H. J. Cole, of New York, N.Y.

2nd Vice-President—John Marshall, Regina, Sask., Can.

Directors—W. B. Bamford, of Belmar, N.J.; Carl Weber, of Los Angeles, Calif.; C. A. Mees, of Charlotte, N.C.

President Gillette then assumed the chair, and after some introductory remarks he called for a report of the treasurer, which was presented. This was followed by a report of the secretary, in which he outlined the work accomplished by the society during the past year Among other things, the secretary stated that 130 new members had been added to the rolls of the society during 1911, an increase of 20 per cent. of the active membership.

This was followed by discussions relative to various features of the work to be done by the society, among which is the gathering of cost-data.

Mr. Shannon, of Jersey City, and Mr. Bosch, of Harrisburg, both contractors, stated that, in their opinion, it could not be expected that contractors, generally, would care to divulge their costs, since they usually consider this information as their personal property, or what may be called their trade secrets. Mr. Frank B. Gilbreth, the well known contractor, however, took the view that contractors are bound to benefit from interchange of ideas and publication of costs. He stated that if many of the contractors who bid on construction work only knew more about costs there would be less ruinous bidding than there is at the present time. It has been the experience of large manufacturers that they have benefited from the publication of their costs in full detail, by the fact that competitors could see for themselves that the margin of prolt was not so large as to allow great risk to be taken.

It was agreed, however, that cost-data of itself has not much value unless together with it is given full details of the method of doing the work, the character of labor, hours of work and an explanation of all conditions that would affect the cost.

At the evening meeting the elected president, Major C. E. Gillette, delivered an interesting address in which he pointed out that the society, although it is an association of contractors and engineers is, primarily, organized to do something for the public good. Major Gillette also pointed out that, whereas every class of labor is organized, contractors alone are not.

He stated that this society should take steps to point out and eliminate waste in large works, waste which is often due to errors in design. Very few designs are made from the point of view of final cost, and in that respect much benefit should result from co-operation and interchange of ideas between engineers and contractors.

Another feature in contracting work, which causes the contractors great loss, and which, ultimately, affects the public, is unreasonable inspection. This requires attention, because unfair inspection has been the cause of much trouble in contract work. The United States Government, particularly, suffers from that trouble, and it is doubtless the reason why it must pay much more for structures of any kind than private individuals or corporations.

Major Gillette recommended that the society use its best efforts to write on the statute books of at least one State, a good, complete, real law that will require fairness, and the avoidance of favoritism and graft in public, government, state, and municipal contracts. By doing that one thing, the society will have justified its existence over and over again. Of course, it is appreciated that it is not possible to legislate honesty into public officials, but, at least, a valid and comprehensive law of this kind, backed by the active influence of a large organization, will doubtless serve to make the way of the trangressor much harder than it is at the present time.

The next point that the speaker referred to was the question of practical specifications. Only too often specifications are written that would require a miracle to carry out, in fact, they are an absolute impossibility; yet contractors are constantly asked to bid on such specifications and they must do it, if they want work. The result is that no end of trouble is experienced. Ultimately the cost must be shouldered by the public, who is powerless to prevent it. Therefore, it behooves an organization like this society to avail itself of the unexcelled opportunity that is now available to accomplish something of lasting benefit, not only to contractors, but also to the public.

The remainder of the evening was devoted to a talk by Mr. J. R. Wemlinger, on "Methods and Costs of Driving and Pulling Steel Sheet-Piling." This was illustrated by means of one hundred and twenty-five lantern slides, showing all known methods of installing sheet-piling of all kinds in United States and foreign countries.

The headquarters of the American Society of Engineering Contractors are at 13-21 Park Row, New York City.

AMERICAN WATER WORKS ASSOCIATION.

The thirty-second annual convention of the American Water Works Association will be held at Louisville, Ky., June 3rd to 8th, 1912, with headquarters at the Seelbach Hotel. Alex. Milne, President; J. M. Diven, Secretary.

CONTRACTS FOR THE SUPPLY OF ELECTRIC POWER FROM THE POWER USER'S POINT OF VIEW.

VI.

By H. E. M. Kensit, M.I.E.E.

The clause dealing with penalties for failure of or interruption in the supply is a thorny one, but usually fully understood in its legal aspects by the lawyers responsible for settling the contract. There are, however, certain considerations due to inherent necessities and probabilities in ordinary operation of the power plant that should be taken into account.

It should be borne in mind that any customer's own power plant must, and inevitably will, sooner or later break down or need stoppage at inconvenient times for repairs, and in many cases such stoppage may be seriously prolonged by the necessity of sending to distant points for new parts or skilled workmen. The risk of lengthy interruption in the supply from a power company is less than in the case of a private plant, because the power company has usually reserve plant, a full stock of spare parts, and skilled men at hand to carry out repairs. It is but seldom that a power company can be charged with negligence in regard to maintaining the supply, but nevertheless all moving machinery must need stoppage at times and all transmission lines must need repair from time to time.

The conditions of the penalty should, therefore, be reasonable, both as to duration of interruption and payment.

As the drafting of the penalty clause is generally a contentious matter, the following examples from some existing contracts may be useful for reference:—

(1). "Accidental Interruption.—This agreement to furnish electric energy is made expressly subject to interruptions or diminutions in the supply of said energy which may be due to causes beyond the reasonable control of the power company, provided that in any such case there shall be an abatement in the payment by the customer to the power company amounting to twice the sum which the customer would have paid for the actual time of each interruption for the quantity by which the supply of electric energy is diminished during the interruption. The power company shall not be liable for any further loss or damage with respect to such interruptions or dimensions beyond such abatement in the payment as aforesaid.

"Intentional Interruption.—If it becomes necessary for the purpose of repair or other good cause to make an intentional interruption, the power company shall give due notice to the customer and make such interruption at that time during the 24 hours following receipt of said notice as shall be reasonably selected by the customer, and such interruption shall not last for more than one hour in any consecutive 24 hours, nor shall the total number of such intentional interruptions amount to more than six in any calendar month, provided further that, should such intentional interruptions extend beyond the above specified periods a deduction shall be made from the payment for energy of a sum equal to twice the amount which the customer would have paid for a supply during the periods of interruption in excess of those specified above."

In the above case the supply was to a factory operating 24 hours a day, so that interruption at any hour represented loss to the customer.

(2). "That in case the producer shall not at all times furnish said energy as aforesaid, it will rebate to the customer such sum as equals the charge made by it against the customer for energy for and during the period of time only wherein energy has not been so furnished, and such rebate is hereby fixed as liquidated damages for and on account of such failure to furnish said energy, and shall be received by the consumer as in full settlement by the producer of all claims and demands of the consumer for injury and loss directly and indirectly resulting by reason thereof."

(3) "The power company shall not be liable for any penalty on account of breakdown of their generating plant, transmission line, transformers, or other apparatus, but the power company hereby agrees that should it make default after the above specified date for the commencement of supply in affording a full and sufficient supply of energy as provided in this agreement (such default not being due to breakdown or to stoppage for temporary purposes at a time agreed upon with the customer), the power company shall be liable to pay to the customer a penalty of $10 per hour during the continuance of such default. In the event of the power company failing to supply from any cause for a week at one time or 10 whole days in one month, the customer shall have power, by notice in writing to the power company, to cancel this contract."

(4). "In case the commission or the company should at any time be prevented from delivering said power or any part thereof.....by strike, lock-out, riot, fire, invasion, explosion, Act of God or the King's enemies, or any other cause reasonably beyond their control, then the commission shall not be bound to deliver such power during such time.....

"If and so often as any interruption shall occur in the service of the company due to any cause or causes, other than those provided for by the next preceding paragraph hereof, the commission shall recover and pay to the said corporations as liquidated and ascertained damages, and not by way of penalty, as follows: For any interruption of less than one hour, double the amount payable for power which should have been delivered during the time of such interruption; and for any interruption of one hour or more, the amount payable for the power which should have been delivered during the time of such interruption and twelve times the last mentioned amount in addition thereto." "Hydro-Electric Commission of Ontario."

The above clauses cover quite a wide range of conditions and ideas as to how they should be met.

When such a clause is under consideration both sides are financially interested and biased; the power user often forgets the risk he has been running of heavy loss from the breakdown of his private power plant and endeavors to exact the largest penalty possible for any interruption, however short; the power company wish to avoid all liability as far as possible.

Let us endeavor to examine in a disinterested way what are the conditions under which it is reasonable to exact a penalty for interruption of supply.

The interruption or diminution may occur from:—

(1). Intentional Stoppage for necessary repairs, connection of new customers, etc. The time of such stoppage can generally be arranged with the customer to cause him no inconvenience, but the clause should call for as long notice as possible and guard against too long a stoppage overlapping with working hours. If this occurs, or if it is a case of a works operating the whole 24 hours, then a rebate on the account for power is just and reasonable.

(2). Unforeseen Breakdowns of plant, lines or other apparatus. In spite of every diligence and foresight such occurrence must happen sometimes. When they do it generally causes more direct loss to the power company than to the the individual customer, and furthermore, unexpected and accidental total interruption causes heavy indirect loss to the power company in a loss of prestige and confidence which hinders obtaining new customers at favorable rates. It may usually be safely assumed that the power company will use

more than "reasonable diligence" to avoid such occurrences, and it is not reasonable to exact heavy penalties in such cases.

At the same time the power company have taken a contract to supply power continuously and the matter of breakdown is very largely, though not entirely, in their control; by expending capital in reserve plant and duplicate transmission lines, and employing competent and well-paid assistants they can very largely minimize the risk.

Furthermore, there is always some risk that a breakdown having occurred, the utmost possible will not be done to shorten the time of interruption; to do the utmost possible often involves heavy expenditure to save a few hours, such, for instance, as sending heavy parts of machinery by express instead of freight, executing expensive temporary work, paying high wages for overtime, etc.; it is but human nature that heavy expenditures to save a short time will be shirked if there is no counterbalancing penalty, and yet even a few hours interruption may mean heavy loss to a manufacturer.

The end to be desired, therefore, is not to heavily penalize a company for an unavoidable breakdown, but to secure that the length of interruption is as short as humanly possible.

This might be secured by arranging the penalty on a sliding scale; the penalty for the first hour could be very moderate and thereafter it could increase rapidly with every additional hour of interruption; thus, if it was to start at $10 for the first hour and to increase by 50 per cent., it would be $15 for the second hour, $22.50 for the third hour, and so on.

(3). Shortage of water, ice troubles, or in case of a steam station, shortage of coal, and similar causes.

Barring very exceptional cases, these causes may be considered under the control of the power company, and to be avoided by reasonable foresight and diligence. Contracts should not be taken for the supply of more power than is justified by low-water records for ten years or more, ice troubles can be guarded against by competent engineering and sufficient capital expenditure, shortage of coal can be guarded against by providing adequate storage and using foresight and prudence.

The customer should be protected against interruption and loss from such causes, and they might well be specially named in the contract.

(4). Undue Preference.—It sometimes occurs that a power company will favor one customer to the detriment of others. For the purpose of financing an enterprise advance contracts are frequently made at low rates and subsequently other contracts are obtained at more remunerative prices. When it comes, then, to a shortage of power obtainable from the plant as a whole or a shortage due to part of the machinery being "laid off," or to great pressure from a customer having a "pull," or to a question of supplying additional power under the terms of a contract made at low rates, this undue preference is liable to affect the customer, and any customer is entitled to liberal protection against such a contingency

(5). Diminution of the Supply.—It may be considered that variations in the voltage and frequency of supply are equivalent to a diminution in the supply, for such variations, if at all frequent or lasting an appreciable time, may cause more actual loss to the customer by affecting the quantity and quality of his output than an occasional total interruption. Most contracts contain stipulations on this point, but few, if any, specify any penalty for breach, and this being a matter decidedly under control of the power company, the customer should have, and should see that he secures, adequate protection in this matter.

Variations of voltage and frequency were discussed in the previous article of this series.

Summing up the principal points discussed above, it is suggested that the penalty clause should cover:—

(1). Intentional stoppage for necessary repairs, etc., involving a moderate penalty if the stoppage overlaps with the hours when supply is needed.

(2). Unforeseen breakdown, when a moderate penalty is justified, and it is suggested that this might be on a sliding scale depending on the length of interruption.

(3). Interruptions due to shortage of water, or coal, ice troubles, etc., which it is suggested should be specially named in the contract and provided for.

(4). Undue preference by the power company.

(5). "Diminution," due to irregular voltage and frequency.

The last three points are those which, in the opinion of the writer, are most frequently the cause of trouble and loss to the power user, and those on which he should be most fully protected in the contract.

It also appears advisable, though it is not usually done, to embody a clause providing that an interruption lasting more than a certain time, or interruptions occurring with more than stated frequency shall be sufficient cause for the customer to cancel the contract. This leaves the customer an opportunity to change his arrangements if the contract is not satisfactorily carried out.

RAILWAY EXTENSIONS IN BRITISH COLUMBIA.

The announcement of the provincial government's railway policy is awaited with considerable interest. Now that people are coming into British Columbia there is urgent demand for means of transportation to and from the vast unopened districts, rich with resources and abundant with possibilities. The government has proceeded slowly to date with railway matters, but now that there is a demand for lines, it will very probably present a policy that will meet with approval. It will provide for railways on both Vancouver Island and the mainland. The line on Vancouver Island from Nanaimo to Alberni is in operation, and another extension of the Canadian Pacific Railway is proposed to the northern part of the island, which will give transportation facilities to the greater part of that vast undeveloped portion of the province.

The Canadian Northern's line to Barclay Sound provides for the southwestern part, and a line along the west coast north from Alberni, will complete a satisfactory system, though to make it thoroughly adequate some branches will be needed. There are large fishing and lumbering interests on the west coast, and a line will be of great service. The sea voyage is very rough and more than one staunch steamer has been lost on the stormy shores north of Cape Beale.

On the mainland, the biggest proposition is the line to the Peace River district, necessary if Vancouver is to retain the trade of the northern part of the province. Mr. A. G. McCandless, president of the Vancouver Board of Trade, has taken a special interest in this project, realizing how important it will be to this city and Victoria. He outlined the advantages of such a road before the board, and headed a delegation that went to Victoria to bring the matter to the attention of Premier McBride and his colleagues. The reply of the Premier was significant. He stated that the policy of his government contemplated a line through the territory mentioned.

Not only will such a line of railway be the means of the coast cities reaching the Peace River district country direct, but it will open a great extent of country, which now has entry only by trail. True, the Cariboo road runs north from

Ashcroft to Fort George, and has served a good purpose. A railway though, will enable settlers to take up land in the Pemberton and Lillooet valleys, be the means of developing the timber and mineral areas, and will tap a district north of the upper reaches of the Fraser that are now practically unknown. Vancouver wants the construction of the Peace River line.

North Vancouver will be greatly benefited by the extension of the Canadian Pacific Railway around the head of Burrard Inlet into the city on the north shore of Burrard Inlet. Plans have been filed at the registry office in New Westminster for such a line. It will not be very long, but will give North Vancouver direct railway connection, something it does not yet possess. Little thought has been given to the Canadian Pacific Railway in the matter of railway facilities for North Vancouver, and the proposed route is one of the simplest in reaching that city. It was to bring railways to the north shore that the bridge across the second narrows of Burrard Inlet was proposed, the construction of which is almost assured. It was concluded that with a suitable bridge over the inlet, the Vancouver, Western and Yukon, which holds a charter for construction to the north, would cross the inlet from its Great Northern connection, and probably go farther north.

The contract has been let for the construction of a plant for the Portland Cement Construction Company, a branch of the Associated Portland Cement Companies of London. This will be the second plant on Tod Inlet, Vancouver Island, and will be directly opposite the operating works of the Vancouver Portland Cement Company, established eight or ten years ago, and of which Mr. R. P. Butchart is general manager. The new plant will be one of a series to be constructed by the Portland Cement Construction Company across Canada, and the approximate cost is placed at $1,000,000. The contract has been awarded to the McAlpine, Robertson Construction Company, which has offices in Vancouver, and which is a branch of Robert McAlpine & Sons, of Glasgow and London.

Doubling of its power supply is the improvement already under way by the British Columbia Electric Railway Company. The company has a large plant on the north arm of Burrard Inlet, and it is proposed to construct another tunnel to Lake Buntzen and duplicate its generating plant on the shore of the inlet. It is proposed also to increase the output of its auxiliary steam plant from 12,000 to 20,000 horsepower. This will give 105,000 horsepower, and the work will involve the expenditure of approximately $1,000,000. An effort will be made to complete the work at the end of the present year. Three Doble waterwheels, with a capacity of 14,000 horsepower each, will be needed and the contract for these has been let to the John McDougall Caledonian Iron Works Company, Limited, of Montreal. The generators will be manufactured by Messrs. Dick, Kerr & Company, London. This work will be the largest development enterprise in hand for the present in the province.

WORLD'S CONSUMPTION OF BUNKER COAL.

The suggestion that the opening of the Panama Canal may render feasible the establishment of a great American station for supplying coal from the mines of the United States to vessels of the world lends interest to an estimate prepared by the Bureau of Statistics, Department of Commerce and Labor, of the coal consumption on the oceans of the world. The statement estimates the coal consumed on the oceans of the world at approximately 75 million tons per annum, valued at over 250 million dollars.

An exact statement of the quantity of coal consumed by the merchant marine and navies of the world cannot be made, owing to the fact that comparatively few countries state the quantity of coal supplied to vessels for their own use, or for "bunkering" purposes. The United States statistics show about 9 million long tons supplied to vessels at ocean ports to be placed in their bunkers for their own use, and the British reports show about 20 million long tons supplied to vessels in the foreign trade and 2½ million tons to vessels in the coastwise trade. This would make for the two great coal producing countries of the world—the United States and the United Kingdom—a total of over 30 million tons supplied directly to vessels for "bunkering" purposes. In addition to this, however, a very considerable percentage of the coal sent out of Great Britain as "exports" passes to ports and stations in various parts of the world from which it is finally supplied to ocean vessels for fuel purposes. A paper presented before the Royal Statistical Society of England by D. A. Thomas, M.P., stated that:

"The great bulk of our export of coal is for the use of steamships, and it is within the mark to say that over half of our exports are for navigation purposes. . . .Cardiff alone ships over a million tons annually to Port Said, over a half million to Malta and Gibraltar, about the same quantity to Cape Verde and the Canaries, over 300,000 to Colombo, and large quantities to Aden, practically the whole of which goes to bunker steam vessels calling to coal at these depots."

As the British exports of coal, aside from that recorded as supplied to vessels for fueling purposes amounted in 1910 to over 62 million long tons, the above quoted estimate would seem to justify adding to the 30 million tons recorded as bunker coal by the United Kingdom and the United States another 30 million as the share of British exports which finally becomes bunker coal through purchase for bunkering purposes at ports or stations to which it was originally exported. While the Bureau of Statistics is unable to state the share of American coal exports which become vessel supplies (aside from that actually reported as bunker coal and not included in the export statement) it is quite probable that a considerable percentage of the coal from the United States which passes to the West Indian Islands and the coast of Mexico, is used for vessel fueling. Add to this the more than two million tons supplied by the Japanese mines to vessels engaged in the foreign trade, the more than 1 million tons supplied from Australia, the nearly 1 million tons supplied from India, plus the estimated consumption of about 3 million tons by the navies of the world, and the Bureau of Statistics estimate of an average of 75 million tons consumed on the oceans of the world seem a conservative one.

The United States is by far the largest coal producer of the world, its production in 1910 being 441½ million metric tons, against 264½ million by the United Kingdom, 222 million by Germany, 39 million each by France and Austria-Hungary, 24½ million by Russia, 23 million by Belgium, 15 million by Japan, 14½ million by China, 13 million by Canada, and 12 each by Australian and India, the grand total of production in 1910 for all countries for which statistics are available being a little over 1 billion tons, of which about 40 per cent. is produced by the United States, about 23 per cent. by the United Kingdom, and about 20 per cent. by Germany.

The coal beds of the United States contain large quantities of coal especially suited to steamship use by reason of steaming qualities, freedom from danger of spontaneous combustion, and proximity to the seaboard. Canada will figure higher in the list in due time, and the opening of the Panama Canal should assist that end.

LOSS OF HEAD IN THE FLOW OF AIR.

The following information on friction loss in the flow of air is abstracted from Catalogue No. 137 of the Green Fuel Economizer Co.:

Loss of Head by Friction of Air in Pipes.—Friction or resistance to the flow of air through a flue or conduit can be expressed as a negative head to be subtracted from the total head possessed by the air before passage through the pipe. The head lost in friction varies with the velocity, the roughness of the enclosing surface, curvature of the channel and the form of the cross-section; it also depends upon the viscosity, which varies with the temperature. Moreover, the drop in head follows at high velocities a law different from that holding for low velocities. That is, below the so-called critical velocity the drop is proportional to the velocity, while above the critical velocity it becomes proportional to the square of the velocity. In flues of ordinary cross-section and with the velocities common in fan practice, the flow is turbulent, that is, above the critical velocity. For this condition the following expression for loss of head due to frictional resistance may be used, namely,

$$Hf = U^2 \, Y \, L \, Z \div 2g \, Q,$$

in which Hf is head in feet of air, [2]U is the velocity in feet per second, g the acceleration of gravity (= 32.17), Y a coefficient of friction, L the length of the pipe in feet, Z the perimeter of the pipe in feet and Q the cross-section in square feet. Values of Y are given on the accompanying chart. This gives the head lost in friction only and is not to be confused with the total loss of head required to force air through the pipe, since the head required to give the fluid velocity through the pipe is ordinarily included in the latter. Also, it applies only to straight parts of the flue. Bends and obstructions in the pipe will cause additional losses of head.

$$Hb = \frac{U^2}{2g} (b_1 + b_2 + \text{etc.}),$$

wherein b equals 1.1 for right angled sharp corners.

0.3 for sharp angles of 135 degrees,

0.25 for a right angled bend of which the radius is equal to the diameter of the pipe.

0.15 for a right angled bend of which the radius is 2 to 4 times the diameter of the pipe,

0.07 for a right angled bend of which the radius is 5 to 6 times the diameter of the pipe,

Zero for bends of which the radius is more than 6 times the diameter of the pipe,

0.15 for a branch turning off at 135 degrees.

1.5 for a grill or register of which the free area is one-half the total area and the free area is equal to the cross-section of the pipe line,

0.75 when the area of the register is one and one-half times the cross-section of the pipe.

When the free area of the grill or register is 0.2 that of the total grill, b = 2 when the free area is equal to the area of the flue and 1.0 when it is equal to 1½ times the area of the flue.

For sudden changes in the cross-section of the flue, $b = [(Q_1 \div Q_2) - 1]^2$, in which Q_1 is the cross-section of the large pipe and Q_2 the cross-section of the small pipe and b is used in connection with the velocity in the large pipe.

Loss of Head Through Orifices, and Equivalent Orifices.—Since the head required to produce a given flow, S, of air through an orifice increases as the square of the flow, and since the head required to overcome the friction of bends, contractions and other obstructions in the air circuit also increases as the square of the flow, we may write the equation of the complete circuit as follows:

$$H = R \, S^2$$

wherein H is the total head required to force the volume S in cu. ft. per second through a circuit of which the total resistance is R. If R be expressed in appropriate units, 1 ft. head of air will produce a flow of 1 cu. ft. of air per second, through 1 unit of resistance.

Experiments made by W. N. Shaw indicate that such a unit or standard resistance would be that of an orifice in a thin plate of area a, where $a^2 = 1/27$ or a = 0.189 sq. ft. If the aperture is circular and of diameter d, then $(\pi d^2) \div 4 = 0.189$, or d = 0.498 ft. In other words, a circular aperture of a diameter of about 6 inches, will have unit resistance according to the above definition. Since the head consumed

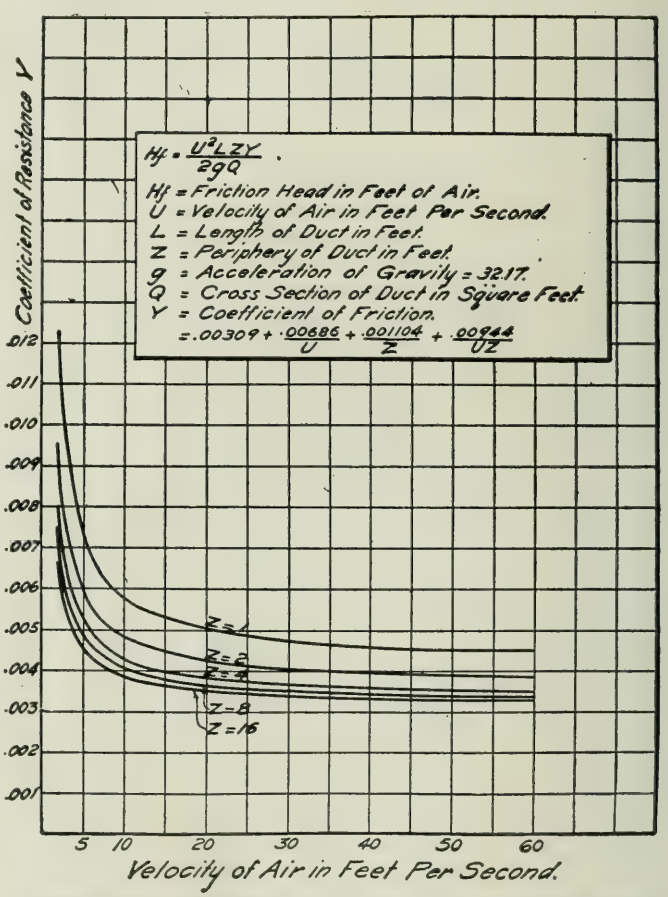

Chart Giving Coefficient of Friction Y for Smooth Sheet Iron Pipes.

by resistance increases as the square of the velocity of flow, it will further appear that the resistance of an orifice varies inversely as the square of the area of the orifice.

When different resistances are passed in series by the current of air, the total resistance of the circuit is the sum of the pneumatic resistances of the several parts arranged in series. For instance, suppose a room to have on one side an inlet orifice 6 in. diameter and on the opposite side an outlet orifice 1 ft. diameter. The resistance of the inlet orifice, according to the above definition, will be 1. The area of the outlet orifice is four times as great as that of the inlet orifice, and the resistance will therefore be 1/16 and the total resistance encountered in forcing the air into and out of the room will be 1 1/16.

[2] Head of feet of air may be converted into pounds per square foot by reference to Table I., and this to inches of water by multiplying by 12/62.4.

If air flows from one point to another by two different paths simultaneously, the drop in head over each path will be the same. If the resistances of the two paths are R_1 and R_2 respectively, we will have the equations

$$H = R_1 S_1^2$$
$$H = R_2 S_2^2 \text{ and}$$

also if the total flow is S we will have

$$H = R S^2$$

where R is the resistance equivalent to the combined resistances of the two circuits in parallel.

From these three equations we may easily deduce, since $S = S_1 + S_2$, the following:

$$(1 \div \sqrt{R}) = (1 \div \sqrt{R_1}) + (1 \div \sqrt{R_2})$$

Then if we substitute for R, R_1 and R_2 their equivalents, namely

$$\frac{1}{27a^2} \quad \frac{1}{27a_1^2} \text{ and } \frac{1}{27a_2}$$

where a, a_1 and a_2 are the respective areas of the equivalent orifices, we have $a = a_1 + a_2$, or in words, the combined air-passing capacity of orifices or channels in parallel is the same as that of a single channel whose equivalent thin plate orifice is equivalent in area to the sum of the areas of the equivalent thin plate orifices for the separate channels.

We may, therefore, speak of the thin plate orifice equivalent to the resistance of a mine, although the mine may contain many passages in parallel and series. Or we may speak of the equivalent orifice of a duct or a complex ventilating system, or the equivalent orifice corresponding to the grates, the fuel on the grates, the boiler passages and the chimney of a steam boiler plant. Or, if we know the equivalent orifices of the several parts which are arranged in series and in parallel, we can easily calculate the equivalent orifice of the whole.

Shaw's experiments are based on the use of a circular orifice in a thin plate, and a comparison of his formula,

$$H = \frac{1}{27\ a^2} \times S^2,$$

with the formula for falling bodies

$$U^2 = 2g\ H,$$

wherein g = acceleration of gravity and U = velocity in ft. per sec., will show that the coefficient of this thin plate orifice works out as 0.653. That is, only 65.3% as much air is passed through the orifice as would be passed if the whole orifice were occupied by a stream moving with the velocity U theoretically due to the head H. Orifices of different shapes and with different conditions of approach or efflux, have different coefficients. For instance, if the up-stream side be provided with a raised edge the coefficient will be reduced to about 0.5. If the collar is on the discharge side, however, and is extended to form in effect a long pipe, the coefficient will be increased to a value approaching 0.83.

AN ACT TO CHECK THE SPREAD OF TYPHOID.

The following is the text of a bill now before the Senate, which is of interest to all engineers dealing with sanitary matters:—

1. The Criminal Code is hereby amended by inserting therein, immediately after section 222 thereof, the following sections:

"222a. Every one is guilty of an indictable offence, and liable to one year's imprisonment, who endangers the lives or health of the public by emptying or depositing any excreta, whether solid or liquid, from a typhoid fever patient.

(a) into, or on the banks of, or near to, any lake, pond, well, river, stream or other water, from which, either directly or at any place lower down in the waterflow therefrom, any city, town, or village is supplied with water for drinking or domestic purposes, or,

(b) into, or on the banks of, or near to, any water discharging into such lake, pond, well, river, stream or other water, or,

(c) into any water-closet, drain, ditch, conduit, or sewer so discharging, or,

(d) into any privy or cesspool, or,

(e) by making any other disposition of such excreta, except as hereinafter specified.

"222b. Every one is guilty of an indictable offence, and liable to one year's imprisonment, who,

(a) being a medical or other attendant upon any person, and knowing that person to have typhoid fever, fails or neglects to give notice immediately to the health-officer of, or to the mayor or other head officer of, the municipality in which that person is being attended, or was attended, that the person had typhoid fever; or,

(b) being such health officer, mayor or other head officer, and having received such notice, fails or neglects to make promptly effectual arrangements to have the excreta, both solid and fluid, of such person treated with carbolic acid or such other disinfectant as will effectually destroy all bacilli and germs therein, and to have the said excreta after they have been disinfected, buried in the earth at least three feet below the surface of the ground and at least three hundred yards from any lake, river, pond, stream, drain, ditch, conduit, sewer or other waterway."

2. Section 223 of the Criminal Code is hereby amended by substituting for the words "last preceding section" in the third line thereof, the words "three sections last preceding."

3. In every city, town, or other municipality wherein a case of typhoid fever occurs, or has occurred within one year next before the passing of this Act, this Act shall be published at least twelve times in a daily or weekly newspaper in or near the locality where such case occurred.

Metallurgical Comment

T. R. LOUDON, B.A. Sc.

Correspondence and Discussion Invited

MICROGRAPHIC EXAMINATION OF FAILURES.*

J. S. Glen Primrose, A.G.T.S.

The "Metallographic Examination of Engineering Materials" has been so enormously developed within recent years that it has given experts an extremely valuable insight into the internal structure of most alloys, of which iron and steel are the most important, and shows that in many cases the proximate composition, as revealed by the microscope, is of more importance than the chemical composition. Metallography has emerged from the stage of doubt and uncertainty in which it for a time existed, and has now attained a position of practical importance in no way secondary to physical testing or chemical analysis, so that practically every steel works of note possesses a photo-micrographic equipment, and many engineering shops are following suit. The engineer himself may not have the time available during his training to devote to a study of practical metallography, and, even in practice, be unable to perform a microscopical examination for himself; but he should at least have sufficient knowledge of the rudiments of the art, that he can comprehend the report and illustrations of an expert metallographist, and understand how it is possible to arrive at a fairly accurate idea of the life history of the materials with which he has to work, and also ascertain their fitness for any particular purpose.

The chief advantage of metallography over the ordinary methods of chemical analysis is that it is much more rapidly performed, and can deal with portions of metal much too small for analysis, and, further, it reveals the mode of arrangement of the constituents, whose presence only is detected by the analysis. Unlike the ordinary methods of mechanical testing, it can be carried out without destroying or even injuring the test-piece, which for micrographical purposes need not be detached from the work. The microscopical examination cannot only be done before putting the material into service, but it can also be applied in the case of a failure, and the metal right up to the place of fracture can be inspected

After pointing out the limitations of the art, the author described the most modern methods of work applied in a systematic metallographic examination, as also the latest forms of microscopes and the influence of using different methods of illuminating the carefully prepared and polished specimens or micro-sections. The chief micrographical constituents of iron and steel were copiously illustrated by a series of original micrographs, showing the effect of increasing carbon content, also that of mechanical and heat treatment on the structure, as shown by the various magnifications obtained with the metallurgical microscope.

Investigation of Failures.—The general method adopted in examining a case of failure was stated as first consisting in making a chemical analysis to determine faults due to incorrect composition or segregation of impurities. Static or dynamic tests follow to show up the defects arising from incorrect working of the material; and, as a final word, sections are examined microscopically to discover if wrong heat treatment or fatigue has been put upon the metal. Each method can afford independent evidence, but conclusions drawn from the combined results usually give the true solution.

FIG. 1.—Wrought-iron angle-bar, showing phosphide segregation in ferrite ground mass and black areas of slag. Magnification, 120 diameters.

FIG. 3.—Mild-steel plate, showing irregular arrangement of pearlite in the ferrite ground mass and two circular phosphide segregations. Magnification, 120 diameters.

FIG. 2.—Wrought iron, showing carbide inclusion as a dark band of pearlite in ferrite ground mass and black slag patches. Magnification, 60 diameters.

From the slides shown to illustrate some of the failures investigated by the lecturer photo-micrographs are reproduced on pages 748, 749, and 750. Fig. 1 shows the micrograph made from a portion of a wrought-iron angle-bar, the failure of which caused a serious boiler explosion, attended with fatal results. The actual fracture, which happened to be carefully preserved, showed quite a silky appearance, but a streak about ⅛ in. in from the bend, and parallel to it, exhibited quite a large crystalline structure much whiter than the remainder. The micro-section was taken across this, and shows in the figure quite a marked phosphide segregation running through the ferrite ground mass, and surrounding the elongated slag enclosures. As picric acid was employed in etching, the phosphide showed up highly colored in the actual specimen, although it only appears as a half-tone area in the reproduction. The quality of the metal was not inquired into at the subsequent inquiry, but the analysis give an average value of 0.34 per cent. of phosphorus, which was much too high, even apart from the embrittling manner in which it had segregated as phosphide. Clearly such metal should not have been employed in the position it was.

* Abstract of opening lecture delivered to the Glasgow University Engineering Society.

Another example of brittle wrought iron on investigation showed the fault to be due to the incomplete removal of the carbon, which did not appear unduly high on analysis, but the micro-section (Fig. 2) shows that the rolling had extended it into a flat plate, in which the carbon percentage would approximately be half of 1 per cent., and thus the tubes rolled from this material split, with disastrous results. The micrograph shows the central dark band of pearlite, and on either side the white ground-mass of ferrite with the slag extended longitudinally through it.

thus produced, there are two well-defined phosphide patches in the section, which, although colored in the sample, only show as dark circular stains in the ferrite. The section was taken from a portion of the plate close to the fracture, and the chemical analysis showed 0.14 per cent. of carbon and 0.08 per cent. of phosphorus.

A rail steel of medium-carbon content, which broke under the drop-test, showed the reason for failure very distinctly under the microscope, the micrograph being given in Fig. 4. This shows the much elon-

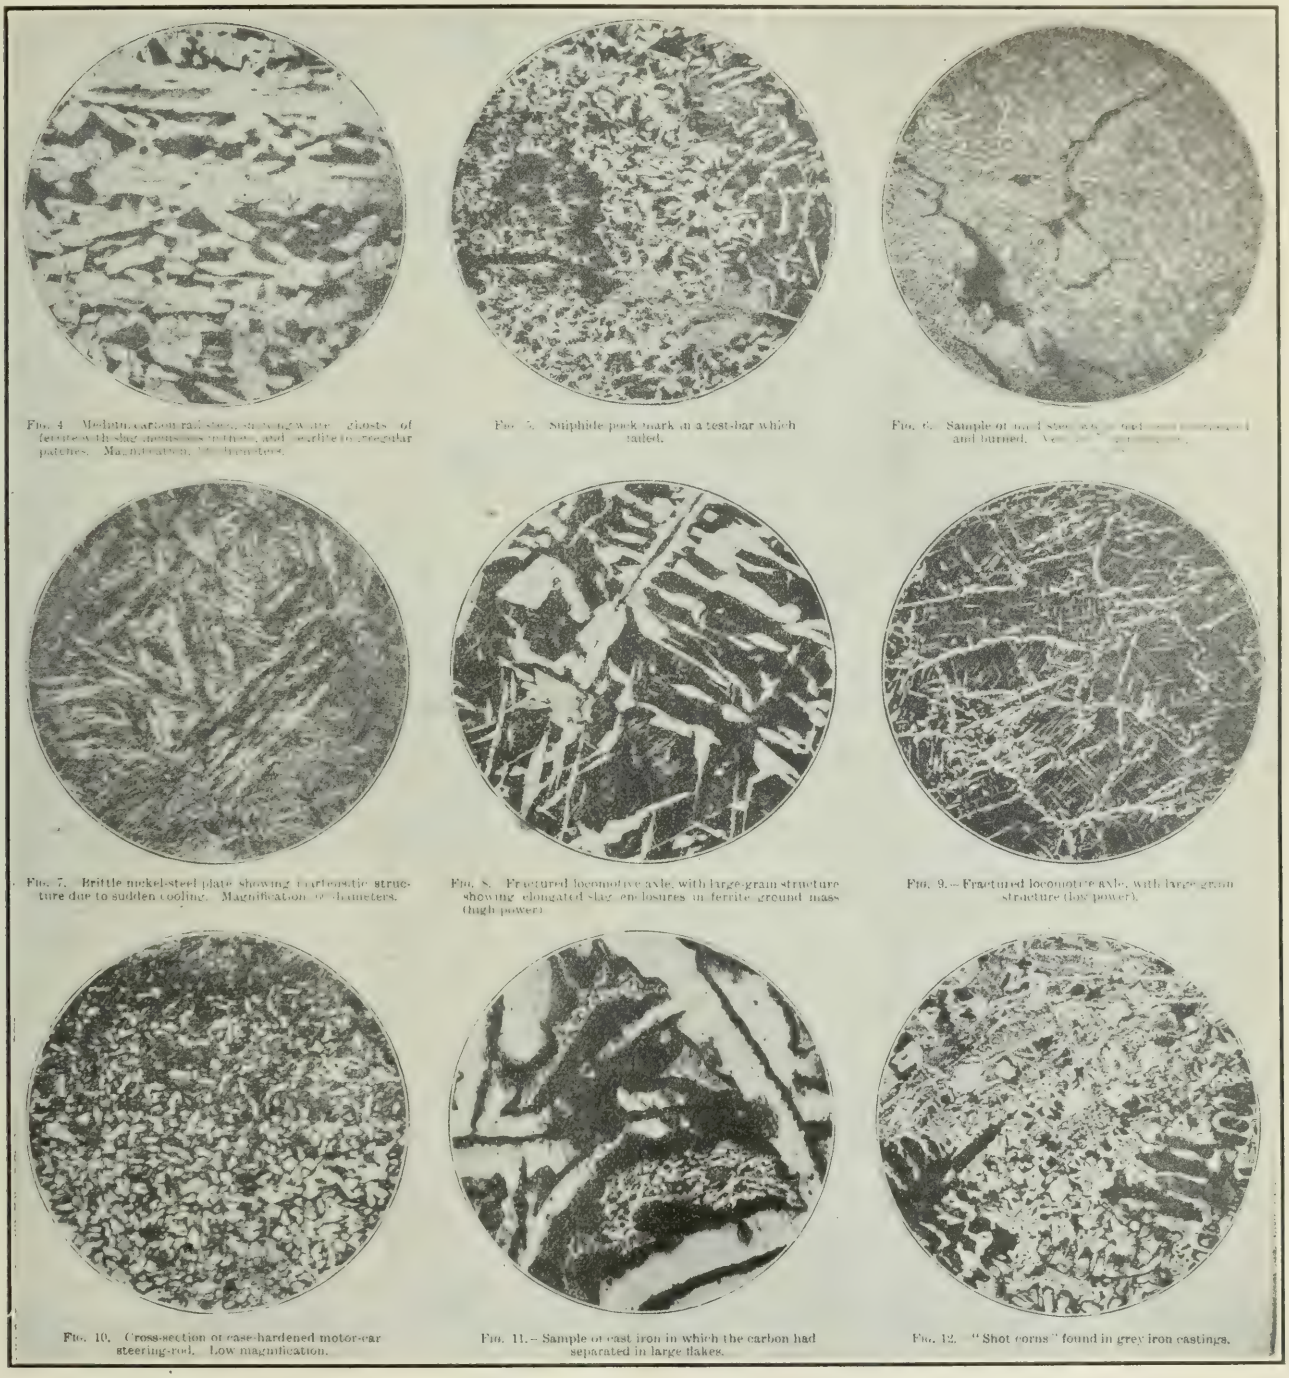

Fig. 4. Medium-carbon rail steel, showing white ghosts of ferrite with slag inclusions outlined, and pearlite in irregular patches. Magnification, 100 diameters.

Fig. 11.—Sample of cast iron in which the carbon had separated in large flakes.

Fig. 12. "Shot corns" found in grey iron castings.

The micrograph reproduced in Fig. 3 was taken from a mild steel plate which fractured very badly on bending, although the test-piece had come up to specification tests. The structure shows a very elongated and irregular arrangement of the pearlite through the ferrite ground-mass, indicating that the metal had been finished at too high a temperature, and either not afterwards annealed, or annealed at too high a temperature. In addition to the brittle effect

gated bands of ferrite, free from carbon, and known as "ghosts," in which has been entangled quite a considerable amount of slag. This is seen to be grey in shade and quite distinct from the irregular pearlite areas, which under a higher power were seen to be well laminated (indicating that the metal had been left to cool slowly from an over-heated condition), and not sorbitic in character, as it would be in a properly-finished rail. The

carbon content was slightly low at 0.3 per cent., but the weakness was undoubtedly due to the structure being traversed by the weak ferrite bands, and also to the slag inclusions which increase the tendency for the metal to split along the "ghosts."

Failure is not commonly due to the presence of sulphur in the form of sulphide segregations, but when these occur the metal is found to be not only "red short," but also to develop brittleness when cold, and fail by fracture under even moderate stresses. Fig. 5 shows the micrograph of a sulphide "pock-mark" noticed in a test-bar which failed to come up to standard. The chemical analysis did not indicate any marked segregation, but close to those parts of the bar at which the skin had puckered in testing, the appearance was found to be very much altered, as seen in the lower part of the micrograph. In this portion both manganese and iron sulphides were recognized, and embedded with these in the ferrite were considerable masses of scoriaceous or slaggy matter.

A very general fault in annealing is to raise the temperature too much, and this gives rise to too large a crystal growth, readily recognizable under the microscope, and even in extreme cases to what is called "burning."

Fig. 6 shows the appearance under a very low power of a piece of over-heated mild steel which has also been "burned." The ferrite ground mass not only shows the large crystal structure and irregular distribution of the pearlite, but heat cracks have made their way into the mass from the edge of the billet and left the characteristic track of oxide film, showing up as a black inclusion. Whilst for over-heating the remedy is proper annealing and rolling or forging, for the defect of "burning" produced in this way there is no remedy, short of remelting the material, if the oxide films have penetrated to any considerable depth.

A somewhat unusual type of brittleness was shown by a consignment of nickel-steel plates, which were unfortunately scrapped before the micrographic examination was made. Along one edge the plates were almost glass-hard, and had considerably damaged the shears employed to cut them. The carbon content was only 0.33 per cent., so that the structure under normal conditions should have been pearlitic; but Fig. 7, under a high power, shows the appearance, which is a strongly martensitic or triangular structure. This brittleness could only have arisen by a drastic quenching, and inquiry elicited the fact that some of the plates, whilst on the cooling bank, had been exposed to the action of a heavy snowfall, which sudden cooling was practically equivalent to quenching. This defect could therefore have been easily rectified by a suitable annealing.

One of the most interesting cases of failure investigated by the author was that of a locomotive axle which fractured while the engine was travelling at express speed, but fortunately without serious result. In the summing up of the inquiry blame was largely thrown upon the design of the built-up axle, and yet the two micrographs reproduced in Figs. 8 and 9 clearly show that the metal was in itself distinctly faulty, even although it has passed specification tests. The chemical analysis gave the carbon content as 0.43 per cent., and the sulphur and phosphorus were well within the limit; but on testing the material for tensile strength it broke at an ultimate stress of 30½ tons per sq. in., and gave an extension of only 6¼ per cent. on the 3-in. test-piece, which was the largest size available. The low-power micrograph (Fig. 9) indicates from the large size of the grain structure that the metal had been left after manufacture in a brittle or overheated condition, possibly due to incomplete mechanical working, or the finishing of this at too high a temperature. The strongly marked lattice-work arrangement of the ferrite around and through the pearlite is characteristic of brittle and untrustworthy material. The higher magnification (Fig. 8) shows a further source of weakness by reason of the presence of elongated slag enclosures in the ferrite ground mass, and both of these defects had evidently given rise to the conditions favorable to developing "fatigue" of the metal from which it finally fractured.

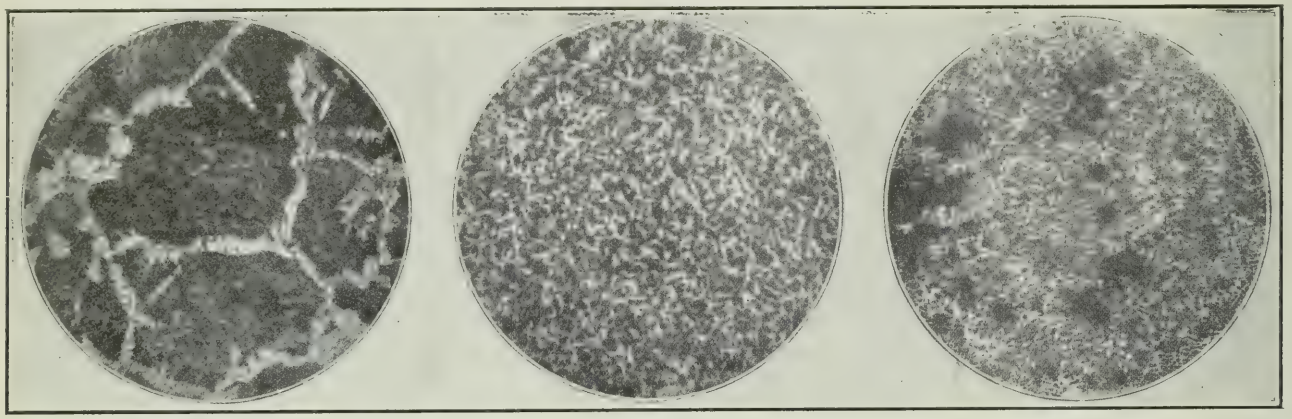

FIG 13.—Motor-car axle before annealing.

FIG. 14.—Motor-car axle after annealing and fairly rapid cooling.

FIG. 15.—Section of cast-iron water-pipe with blow-holes

Such metal could undoubtedly have been restored to a proper condition by a suitable annealing and fairly rapid cooling before being put into use, and instances were quoted to show how motor-car axles which developed serious brittleness had been heated and oil-quenched to produce the necessary reduction in the grain size and uniform distribution of the pearlite to give exceedingly durable material (Figs. 13 and 14).

The failure of a motor-car steering-rod, due to fracture, was shown to be due to the imperfect case-hardening of the material. Fig. 10 shows the micrograph of a cross-section near the point of fracture, and shows, even at the low magnification, the very sharp line of demarcation between the martensitic structure of the outer edge (shown at the top) and the mild-steel centre containing the ferrite ground-mass with small quantities of pearlite. Evidently a small heat or surface crack had penetrated the hardened skin, which, not being well cemented to the core, had yielded under the stress of a sudden twist.

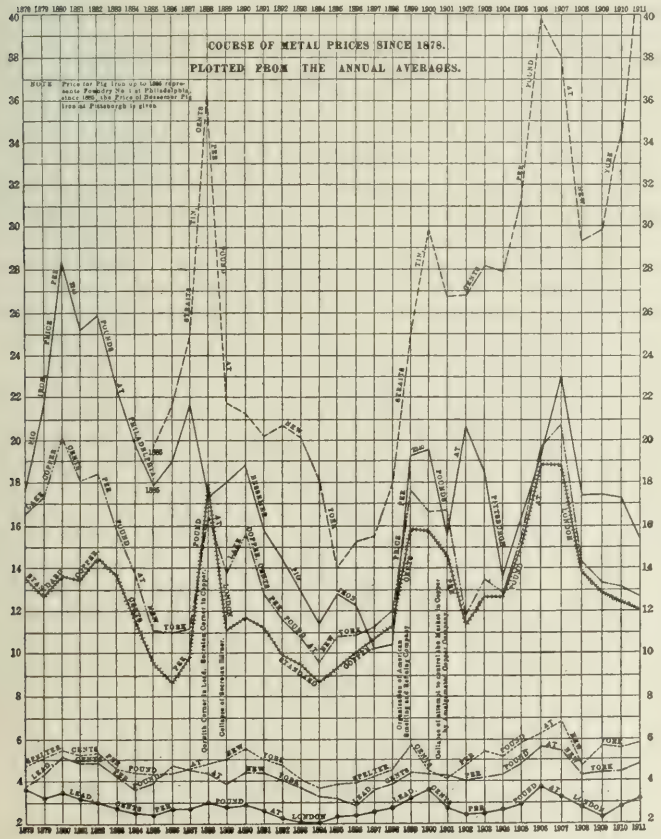
Cast iron is not usually called upon to withstand heavy stress put upon it, but hydraulic castings occasionally fail in a way which may appear mysterious without the aid of the microscope. One peculiar case of the failure of a heavy casting while in service was investigated, the test-bar having given entirely satisfactory results. It had cooled at a much

quicker rate than the metal in the casting, which was rather high in silicon for the thickness employed, with the result, as shown in Fig. 11, that the carbon separated in very large flakes, which were without doubt the cause of fracture. The metal was also weakened by the considerable degree of segregation of the iron phosphide, which appears as the eutectic mass enclosed within the dark pearlite areas.

Sometimes even grey iron castings fail on account of the separation within them, of minute "shot corns" or bullets of a very hard material, often attributed to chilled metal. In nearly every instance of such defects investigated by the author these were shown to be due rather to eutectiferous segregation of iron phosphide. These bullets are often much too small for analysis, but the microscope reveals the characteristic eutectic structure, as shown in Fig. 12, which not only illustrates the peculiar manner in which the pearlite areas are affected, but indicates how the iron phosphide can separate out in lozenge-shaped crystallites when above the eutectic proportion. This makes the portion of metal extremely hard and brittle to shock.

Blow-holes in castings are responsible for many failures, particularly in instances where the metal is desired as hard and close in the grain as possible. Fig. 15 illustrates the micro-structure of a water-pipe which failed badly under pressure, owing to the defective manner of casting, which had evidently produced too sudden a cooling. The ground mass had been converted into the cementite characteristic of a white iron, and the large amount of contraction had led to the formation of unsound patches in the interior of the metal, indicated by the dark holes scattered throughout the pearlite areas.

The lecturer claimed that there were many cases in which the microscopieal examination of metal before use would prove a great service to the engineer, particularly in preventing the use of faulty material unsuited for the purpose to which it was to be put.



ENGINEERING NOTES.

Ottawa, Ont.—The operation of the municipal electric light plant during the year 1911 was the best in the six years during which the plant has been owned by the city. A net profit of $27,716.37 is shown in the annual report. During the year $34,000 was spent on extensions to lines. The cost of constructing the white way, three miles in length, was $21,194. On the new conduit between the power house and the distributing station $38,505 was spent.

* * * *

Fredericton, N.B.—It is reported that Sir Thomas Tait, president of the Fredericton and Grand Lake Coal and Railway Company, has increased his holdings in the New Brunswick coal areas by the purchase of 112 acres of coal property.

* * * *

Montreal, P.Q.—The plans of the Harbor Board include the extension of Alexandra and King Edward Piers, the construction of a new pier to be known as No. 1. Two lift bridges, with railway and roadway accommodation, will be flung across the basin to the Guard Pier, where 1,600 feet of new wharf is to be built, thus materially increasing the accommodation of the port.

The construction of islets or anchorage banks in the Laprairie Basin, to hold the ice until melted in the spring.

The construction of grain elevator No. 2, and jetty at Section 19, with conveyors reaching adjacent piers.

The improvement and extension of the Harbor railway tracks from Victoria Pier to the Racine Wharf above winter water level, so as to be useful both summer and winter.

Completion of Victoria Pier and Market Basin, giving 2,700 lineal feet of high level quays for ocean steamers, with a depth of 35 feet at low water, and 4,000 lineal feet at low level quays for river vessels.

The erection of permanent sheds on the new Victoria high level quays, including equipment.

The lengthening of the Alexandra and King Edward Piers to about 1,200 feet each, and of the Jacques Cartier Pier to 1,100 feet, and a corresponding lengthening of the sheds upon them.

PERSONAL.

Mr. Charles Brandeis, C.E., of Montreal, has been appointed consulting engineer to the Saraguay Electric & Water Company, in place of his previous appointment, as chief engineer.

Messrs. Mitchell, Wilson and Holloway have been selected by Mr. L. E. Cousins to assist in the engineering work of the Harbor Board. These gentlemen were employed in the city engineer's department of Toronto.

Mr. J. P. Gordon has been appointed assistant chief engineer of the Hudson Bay railway. Mr. Gordon has been in the employ of the Hudson Bay railway two years in the capacity of locating engineer. Prior to this connection he held various engineering positions with several roads. His work has been entirely restricted to Western Canada. He held the position of locating engineer with the Great Northern railway in British Columbia for five years. Prior to that he was for about five years resident engineer with the Canadian Northern railway on the Prince Albert, Saskatchewan and Edmonton branches.

ENGINEERS' CLUB OF TORONTO.

The elections of the Engineers' Club resulted in the following gentlemen being appointed directors: Messrs. L. E. Cousins, A. J. Van Nostrand, A. L. McAllister, James McEvoy and George Powell. The election of the new officers will take place in the near future.

The statement prepared at the close of December, 1911, showed a membership of 423, of which there were 2 life members, 317 resident members, 70 non-resident, and 34 associate.

COMING MEETINGS.

CANADIAN FORESTRY ASSOCIATION.—February 7th and 8th, 1912. Forestry Convention Meetings held in the Railway Committee Room, Parliament Buildings, Ottawa. Secretary, Mr. James Lawler, Canadian Bldg., Ottawa.

CANADIAN LUMBERMEN'S ASSOCIATION.—February 6, 7 and 8, 1912. Annual Meeting to be held at the same time and place as the Canadian Forestry Association.

THE ENGINEERS' CLUB OF TORONTO, 90-96 King St. West.—Meeting, Thursday, Feb. 8th, 8 p.m. (in Lecture Room) of Canadian Section of Society of Chemical Industry. Address by Mr. F. N. Speller, Metallurgical Engineer, National Tube Co., Pittsburg, Pa., on "The Manufacture of Soft Steel Tubes in Relation to Corrosion." R. B. Wolsey, Secretary.

THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.—Tuesday evening, February 13, at eight-fifteen o'clock, in the Engineering Societies' Building, 29 West 39th St., New York, the American Institute of Mining Engineers co-operating. A paper entitled "Notes on Design and Mechanical Features of the California Gold Dredge" will be presented by Robert E. Cranston, consulting engineer for the Marysville Dredging Co., Marigold, Cal.

THE CLEVELAND ENGINEERING SOCIETY.—Regular Meeting, Tuesday Evening, February 13, 1912, Chamber of Commerce Bldg., Cleveland, O. Address by Mortimer E. Cooley, Dean, Department of Engineering, University of Michigan; Subject: "Public Utilities and Their Relation to the Public." Secretary, F. W. Ballard.

THE ENGINEERS' CLUB OF TORONTO, 90-96 King St. West.—Thursday, Feb. 15th. Dinner at 6-30; Lecture at 8 p.m., in Dining Room. After dinner address by Prof. W. R. Lang, Major Canadian Engineers, "Organization, Administration, Duties and Achievements of the Engineering Forces of the Crown," illustrated with models and lantern slides of Bridges constructed by the Royal Engineers in different parts of the Empire. R. B. Wolsey, Secretary.

CANADIAN NATIONAL ASSOCIATION OF BUILDERS.—The Sixth Annual Convention will be held in Toronto, February 20, 1912.

ONTARIO GOOD ROADS ASSOCIATION.—Annual Convention to be held at Toronto, February 26, 27, 28. Secretary, J. E. Farewell, Whitby.

THE ENGINEERS' CLUB OF TORONTO, 90-96 King St. West.—Thursday, Feb. 29th, 8 p.m. Meeting of Toronto Branch of Canadian Society of Civil Engineers. R. B. Wolsey, Secretary.

THE CANADIAN MINING INSTITUTE.—Annual meeting held in Toronto, March 6th, 7th and 8th, 1912, the American Institute of Mining Engineers co-operating; also important delegates of the Institute of Mining and Metallurgy of Great Britain will be present. Secretary, H. Mortimer-Lamb

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE; Secretary, Professor C. H. McLeod.

QUEBEC BRANCH—
Chairman, P. E. Parent; Secretary, S. S. Oliver. Meetings held twice a month at Room 40, City Hall.

TORONTO BRANCH—
96 King Street West, Toronto. Chairman, T. C. Irving; Acting Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the month at Engineers' Club.

MANITOBA BRANCH—
Secretary E. Brydone Jack. Meets every first and third Fridays of each month, October to April, in University of Manitoba, Winnipeg.

VANCOUVER BRANCH—
Chairman, Geo. H. Webster; Secretary, H. K. Dutcher, 319 Pender Street West, Vancouver. Meets in Engineering Department, University.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, S. J. Chapleau, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings,

MUNICIPAL ASSOCIATIONS.

ONTARIO MUNICIPAL ASSOCIATION.—**President, Chas. Hopewell, Mayor, Ottawa; Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.**

UNION OF ALBERTA MUNICIPALITIES.—President, H. H. Gaetz, Red Deer, Alta.; Secretary-Treasurer, John T. Hall, Medicine Hat, Alta.

THE UNION OF CANADIAN MUNICIPALITIES.—President, W. Sanford Evans, Mayor of Winnipeg; Hon. Secretary-Treasurer, W. D. Lighthall, K.C., Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer, J. W. McCready City Clerk, **Fredericton.**

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bec, Lemberg; Secretary, Mr. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

CANADIAN TECHNICAL SOCIETIES.

ALBERTA ASSOCIATION OF ARCHITECTS.—**President, G. M. Lang; Secretary, L. M. Gotch, Calgary, Alta.**

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—**President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.**

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—**President, N. McMurchy; Secretary, Mr. McClung, Regina.**

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—**President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.**

BUILDERS, CANADIAN NATIONAL ASSOCIATION.—**President, E. T. Nesbitt; Secretary Treasurer, J. H. Lauer, Montreal, Que.**

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—**President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.**

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto.

CANADIAN ELECTRICAL ASSOCIATION.—**President, N. W. Ryerson, Niagara Falls; Secretary, T. S. Young, Canadian Electrical News, Toronto.**

CANADIAN FORESTRY ASSOCIATION.—**President, Thomas Southworth, Toronto; Secretary, James Lawler, Canadian Building, Ottawa.**

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; J. Keillor, Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; **Secretary-Treasurer, Francis** Dagger, 21 Richmond Street West, Toronto.

CANADIAN MINING INSTITUTE.—**Windsor Hotel, Montreal. Pres**ident, Dr. Frank D. Adams, McGill University, Montreal; Secretary. H Mortimer-Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—**President, D. McDonald, Manager, Montreal Street Railway; Secretary, Acton Burrows, 70 Bond Street, Toronto.**

CANADIAN SOCIETY OF FOREST ENGINEERS.—**President, Dr. Fernow, Toronto; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.**

CENTRAL RAILWAY AND ENGINEERING CLUB.—**Toronto, Pres**ident, G. Baldwin; Secretary, C. L. Worth, 409 **Union Station. Meets third Tuesday each month except June, July, August.**

DOMINION LAND SURVEYORS.—President, Thos. Fawcett, Niagara Falls; Secretary-Treasurer, A. W. Ashton, Ottawa.

EDMONTON ENGINEERING SOCIETY.—**President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.**

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—**President, W. B. McPherson; Corresponding Secretary, A. McQueen.**

ENGINEERS' CLUB OF MONTREAL.—**Secretary, C. M. Strange, 8 Beaver Hall Square, Montreal.**

ENGINEERS' CLUB OF TORONTO.—**96 King Street West. President, Killaly Gamble; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.**

INSTITUTION OF ELECTRICAL ENGINEERS.—**President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.**

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian Members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain, and W. H. Miller, and Messrs. W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—**Secretary, R. C. Harris, City Hall, Toronto.**

MANITOBA LAND SURVEYORS.—**President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.**

NOVA SCOTIA MINING SOCIETY.—**President, T. J. Brown, Sydney Mines, C.B.; Secretary, A. A. Hayward.**

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—**President, W. H. Pugsley, Richmond Hill, Ont.; Secretary, J. E. Farewell, Whitby.**

ONTARIO LAND SURVEYORS' ASSOCIATION.—**President, J. Whitson; Secretary, Killaly Gamble, 703 Temple Building, Toronto.**

THE PEAT ASSOCIATION OF CANADA.—**Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.**

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary J. E. Ganier, No. 5. Beaver Hall Square, Montreal.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—**President, F. S. Baker, F.R.I.B.A., Toronto, Ont.; Hon. Secretary, Alcide Chausse, No. 5 Beaver Hall Square, Montreal, Que.**

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—**Dr. A. McGill, Ottawa, President; Alfred Burton, Toronto, Secretary.**

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, J. P. McRae; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—**President, Wm. Pierce, Calgary; Secretary-Treasurer, John T. Hall, Brandon, Man.**

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. Rosevear, 115 Phœnix Block, Winnipeg, Man. Second Monday, except June, July and August, at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc. Printed forms for the purpose will be furnished upon application.

TENDERS.

Calgary, Alta.—Tenders will be received at the office of the Division Engineer, Calgary, until noon of February 18, 1912, for concrete substructures, excavation, etc., for overhead bridges and subway at Edmonton. Full particulars at Chief Engineer's Office, Edmonton; Asst. Engineer's office, Strathcona, and office of N. E. Brooks, Div. Eng., Calgary.

Edmonds, B.C.—Tenders will be received until March 11, 1912, for the supply of about 35 miles of steel pipes, varying in diameter from 3 to 10 inches, for the municipality of Burnaby Water Supply. W. Griffiths, Clerk Municipal Council. (See advt. elsewhere in Can. Eng.)

Moose Jaw, Sask.—Tenders will be received until February 12, 1912, for the erection of the Saskatchewan College and principal's residence, plans and specifications of which may be obtained at the office of R. G. Bunyard, architect, Room 6, Bank of Commerce Chambers, Moose Jaw.

Ottawa, Ont.—Tenders are invited for the construction of a quarantine station at Keremos, B.C., specifications of which may be obtained from Wm. Thompson, V.S., of Keremos, B.C. Tenders to reach Ottawa not later than March 1st, 1912. A. L. Jarvis, Asst. Deputy Minister and Secretary of Agriculture, Ottawa.

Ottawa, Ont.—Tenders will be received by the secretary Board of Control, City Hall, until February 13, 1912, for the supply of broken stone, brick, stone setts, cement, plank and cedar, sand, vitrified clay pipe, asphalt, castings, street sweeper's brooms, hardware, or street sprinkling wagons. Full particulars at office of Newton J. Ker, City Engineer, Ottawa. (See advt. elsewhere in Can. Eng.)

Ottawa, Ont.—Tenders will be received by the secretary of the Water Works Committee, until February 13, 1912, for the supply and delivery of brasswork, special pipe castings, hydrants, cast-iron pipe, lead pipe and pig lead, valves, oils and grease, as the case may be. Full particulars at the office of Newton J. Ker, City Engineer, Ottawa. (See advt. elsewhere in the Can. Eng.)

Ottawa, Ont.—Tenders will be received until February 20, 1912, for the construction of east and west highway approaches to the steel service bridge over the Red River at Lockport, Selkirk County, Man. Plans, specifications, etc., may be obtained at the offices of W. Z. Earle, Esq., Dist. Engineer, 504 Ashdown Block, Winnipeg, Man.; J. G. Sing, Esq., Dist. Engineer, Confederation Life Bldg., Toronto. Ont.; J. L. Michaud. Dist. Engineer, Merchants Bank Bldg., St. James St., Montreal, P.Q.; Postmaster at Lockport, Man., and R. C. Desrochers, Secretary Dept. of Public Works, Ottawa.

Ottawa, Ont.—Tenders for the design and construction of a schooner for Pacific Coast Survey will be received until noon, February 15, 1912. Particulars with the officer in charge, H.M.C. Dockyard, Esquimalt, B.C. G. J. Desbarats, Deputy Minister the Naval Service, Dept. of Naval Service, Ottawa.

Ottawa, Ont.—Tenders for approximately 2,500 feet of 30-inch steel pipe in connection with the West End Drainage System, will be received by the Secretary of the Board of Control, City Hall, Ottawa, until February 15th, 1912, for the supply and laying same in the Ottawa River. Newton J. Ker, City Engineer. (See advt. elsewhere in Can. Eng.)

Toronto, Ont.—It is expected that the Northern Navigation Company will call for tenders in the near future for a 500-foot combined freight and passenger vessel. Mr. James Playfair, Midland, Ont., is president of this company.

Victoria, B.C.—Tenders for the erection and completion of a two-room frame schoolhouse at Port Alberni, in the Alberni Electoral District, B.C., will be received until February 14, 1912, by the Hon. the Minister of Public Works. Plans, etc., at the offices of A. D. Cooper, Secretary of School Board, Port Alberni, B.C.; the government agent, Alberni and Nanaimo; and office of J. E. Griffiths, Public Works Engineer, Dept. of Public Works, Victoria, B.C.

Victoria, B.C.—Bids for the supply of a new motor fire apparatus for the city of Victoria will be called for shortly. The new apparatus will consist of a combination motor hose and chemical wagon, an 80-gallon gas motor chemical and chassis for the present city service truck and engine at headquarters station.

COPIES OF ENGINEER WANTED.

A copy of our issue of March 30th, 1911, No. 13, is required. A month's subscription will be allowed to the party supplying this number.

Copies of the Canadian Engineer of the issue of January 18, 1912, are wanted. By forwarding same to the main office your subscription will be extended over another month.

CONTRACTS AWARDED.

Brantford, Ont.—Messrs. Schultz Bros. Company, Limited, have received the contract for the erection of a two-story schoolhouse on Chestnut Ave. The building will be comprised of basement, 84 x 112 feet, ten rooms, brick with reinforced concrete floors, concrete foundation, steam heating, electric lighting, etc.

Calgary, Alta.—Messrs. Nicholson & Bain, Winnipeg, wholesale commission merchants and brokers, have let a contract in Calgary for the erection of a six-storey solid brick warehouse and office building. It is also the intention of the firm to erect a large warehouse in Edmonton this year.

Carman, Man.—Tenders will be received until noon, February 17th, 1912, for the erection of two bridges over the Boyne River at Carman, Man. Plans and specifications for bridges may be seen at the office of the Manitoba Government Engineer at Winnipeg, Man., or at the office of A. Malcolmson, Secretary-Treasurer, Town of Carman, Man.

Edmonton, Alta.—The contract for the construction of the new municipal library has been let to William Ditz, local contractor, for $24,501.

Montreal, Que.—The contract for the erection of the new immigration buildings at Quebec has been awarded to Messrs. C. E. Deakin & Co., of Montreal. The sheds are to be erected by the government on the Louise Embankment. The new buildings are to be of steel and concrete, two stories high, over 700 feet in length, and will have accommodation sufficient for 1,500.

Montreal, Que.—The Canadian Pacific Railway Company have awarded a contract to Messrs. John S. Metcalf Co., Limited, Montreal and Chicago, for a reinforced concrete storage addition to their elevator at Port McNicholl, Ont. Capacity of additional storage will be 2,000,000 bushels, and estimated cost, together with additions to wharf work to enable travelling marine towers to reach new storage, is approximately $350,000.

New Westminster, B.C.—The contract for the construction of 6,900 feet of jetty at the mouth of the Fraser River has been awarded to Mr. T. F. Sinclair. Mr. Sinclair's tender of $171,000 was the lowest received, the Norton Griffiths Construction Company being second with a bid of $190,000. The other tenders received ranged up to $295,000 for the work.

Niagara Falls, Ont.—The contract for furnishing and installing the heating plant in the city hall has been awarded to J. T. Henderson, of this city, for $1,255. Three bids were received, the highest being $1,292.

Strathcona, Alta.—The Heenan-Frowde Co. have received the contract for the erection of an incinerator, at a cost of $40,200.

Toronto, Ont.—Tenders will be received until February 27th, 1912, for the construction of Toronto Junction Main Sewer, Section No. 4, Bloor St. Tunnel. G. R. Geary (Mayor), Chairman of the Board of Control, City Hall, Toronto. (See adv. elsewhere in the Can. Eng.)

Vancouver, B.C.—The contract for the supply of three large water turbines of 14,000 h.p. each, in connection with the power development of the B. C. Electric Railway, to be placed in a separate generating station on the North Arm of Burrard Inlet, has been awarded to the John McDougall Caledonian Iron Works Company, Limited, of Montreal; and the contract for the electrical generators, each of 9,000 k.w. capacity, has been given to Messrs. Dick, Kerr & Co., of London, England.

Vancouver, B.C.—The Grand Trunk Pacific has placed an order for 10,000,000 feet of lumber, mostly heavy timbers, bridge materials, etc., with the Victoria Lumber Manufacturing Company, of Chemainus, B.C. Lumber to be delivered in Manitoba to be used for construction east of Winnipeg.

NILE BRIDGE CONTRACT.

The tender of a Darlington (England) firm, the Cleveland Bridge and Engineering Company, has been accepted for the construction of a bridge to replace the Pont des Anglais over the branch of the Nile at Cairo known as the Bahr el Aama.

RAILWAYS—STEAM AND ELECTRIC.

Collingwood, Ont.—A report states that the Canadian Pacific Railway are preparing plans for an entry to this port.

Fort William, Ont.—Although there was a profit shown on the operating expenses of the street railway of over $55,000 in 1911, there was actually a loss of about $10,000 on that concern. Mayor Ray stated that the profit made on the street cars would not be sufficient to pay interest and sinking fund by $10,000, and therefore what was apparently a profit of $55,000, was actually a loss of $10,000.

Guelph, Ont.—A report states that the electric road to be built from Toronto to Guelph will go through Acton. Construction is likely to start this spring, but so far the plans of entry into Gelph have not been submitted to the Guelph city council for their approval.

Kingston, Ont.—The Canadian Pacific Railway intends shortly to take over and operate the Kingston and Pembroke Railway, and make extensive improvements.

London, Ont.—The management of the Lake Erie Coal Company have approached the municipal council of London with a view of electrifying the line of the London and Port Stanley Railroad.

Montreal P.Q.—Plans for the alteration of the C.P.R. bridge over Mountain street have been approved by the controllers. In connection with the laying of new tracks it will be necessary to widen the bridge, which already covers in a good part of the street between Dorchester and St. Antoine streets.

Montreal, P.Q.—A report states that the Montreal and Southern Counties Railway Company have under consideration the extension of its lines to Laprairie, Boucherville and Sorel, also having made an arrangement for the electrification and operation of the Montreal & Province Line Railway between St. Lambert and St. Cesaire, intending to extend the line from St. Cesaire to Granby, thereby giving the shortest route between Granby and Montreal.

Nanaimo, B.C.—The city of Nanaimo has given notice of its intention to apply to the legislature for authority to construct a railway from Nanaimo to Brecken, thence to Northfield, to East Wellington, through the Five Acre Lots to Extension, and thence to Nanaimo river bridge.

Ottawa, Ont.—The railway companies of Canada are taking steps to stop the practice of carrying explosives in baggage checked in the usual way and in packages of household furniture shipped as freight.

Port Colborne, Ont.—The Grand Trunk Railway will increase their yard accommodation at Port Colborne, and have leased from the Dominion Government all the government land lying between the Grand Trunk Welland line and Welland street.

Province of New Brunswick.—A third surveying party is to be started on work on the St. John Valley Railway.

LIGHT, HEAT AND POWER.

Montreal, P.Q.—Some weeks ago the Isle Au Heron Development Company filed with the Dominion Government a plan for the development of power at Isle Au Heron, practically opposite the Lachine power site. The drawings submitted show two parallel walls, between which a part of the flow of the river is intended to go and at the end is a concrete dam. The Hon. F. D. Monk announced that nothing, as regards approval of the company's plan or authorization of its undertaking, will be done until the Departmental engineers or the commission on St. Lawrence water power schemes reports fully in the matter.

Montreal, P.Q.—It is stated that the Cedar Rapids Manufacturing & Power Company will call tenders for the dyke and power house without much delay, as it is the desire of the company to begin active operations at the plant in the early spring. Mr. Henry Holgate, C.E., Montreal, is provisional president.

Ottawa, Ont.—A deputation from the Canadian Peat Society, assisted by a committee from the board of trade, will ask the minister of mines to have one or more engineers of his department sent to investigate and report on the

Tarvia

Preserves Roads Prevents Dust

Lancaster St., Berlin, Ont. Roads constructed with Tarvia X Modern Pavement

Meets Modern Road Requirements

TARVIA is a powerful binder for the surfaces and foundations of macadam roads. It fills the voids and locks the stone in a tough, durable, plastic matrix.

A Tarviated surface looks like sheet asphalt and is equally dustless and clean. It sheds water readily and is dry immediately after the rain, so that pedestrians are not inconvenienced. The surface never gets muddy or dusty.

On account of the Tarvia matrix, these roads will bear heavier automobile traffic than plain macadam because the surface yields instead of pulverizing under the strains. The Tarvia matrix prevents internal movement and grinding.

The plasticity of the Tarvia also makes these roads very quiet. Horses' hoofs make almost no sound on a Tarviated road. Tarvia is waterproof, and Tarviated roads, therefore, are protected against damage from torrents on grades.

Tarvia has no odor except when being applied. After it hardens, it has no injurious effect on shoes, clothing or vehicles. The cost of using Tarvia is not a factor for consideration, because it has been repeatedly demonstrated that it is cheaper to maintain a dustless road with Tarvia than a dusty one without it. Maintenance economies more than balance the additional cost.

Booklets on request. Address our nearest office.

The Paterson Manufacturing Co., Limited
Montreal Toronto Winnipeg Vancouver

The Carritte-Paterson Manufacturing Co., Limited
St. John, N.B. Halifax, N.S.

leading peat, gas power installations in Europe. Messrs. G. B. Greene, A. W. Fleck and John McKinley will represent the board.

Ottawa, Ont.—An additional 200 horse-power for the municipal electric plant will be ordered from the Ottawa and Hull Power Company. The order is to date from December 1st last. This will make 3,100 horse-power taken by the city for the plant. The cost is $15 per horse-power, making a total of $46,500.

Prince Rupert, B.C.—The newly formed council have decided to push the hydro-electric work with all possible speed. This work includes the construction of a large concrete dam and the installation of a steel or cast-iron pipe.

Regina, Alta.—The Leader Publishing Company are installing a private power plant and water system in their new building. The company have placed with the British-Canadian Engineering and Supply Company, of Winnipeg, an order for a 100-h.p. Ruston Proctor engine and gas producer plant, together with a 75-k.w. Westinghouse generator. The plant will be utilized at times for pumping water from the well which has been sunk in the basement of the building, and which will furnish a water supply independent of that furnished by the city.

Saskatoon, Sask.—The city commissioners have decided that the wiring for the new lighting standards shall be of armored insulated wire. This will do away with conduits as the wire is buried in a trench. This does away with the difficulty often experienced in handling wires for repair purposes when they are in conduits.

Smith's Falls, Ont.—The Smith's Falls Electric Light and Power Company have installed a new auxiliary steam power plant of the most modern type. The engine is one of the largest of its kind in Canada.

Toronto, Ont.—It is reported that the municipal engineering department will recommend that a water meter be placed in every house and a yearly inspection of mains be made.

Vancouver, B.C.—The engineers at work on the trunk sewers have announced the possibility of tenders being called within the next few days for the construction of work.

GARBAGE, SEWAGE AND WATER.

Brantford, Ont.—During January at the waterworks 86,308,275 gallons of water were pumped as against 75,244,066 gallons in 1911.

Ottawa, Ont.—A sand filtration plant to cost about $2,000,000 has been decided upon by the civic water committee. The municipal engineer, Mr. Ker, has been instructed to make the necessary surveys, etc., and to procure any assistance required. The plant is to be erected on Lemieux Island and the intakes will receive their supply from the river, the present source of supply.

New Westminster, B.C.—The city engineer, Mr. I. W. Blackman, has recommended that a new reservoir be constructed with a storage capacity of 5,000,000 gallons, also the extension of the present reservoir.

Port Colborne, Ont.—The Canadian Union Furnace Co. will put in its own waterworks plant and fire protection. If the town so desires the municipal system can be connected up with the company's system, and in case of a big fire or other necessity the company's supply will be at the disposal of the town.

Toronto, Ont.—The estimates of the property commissioner for 1912 include the following items:—Scavenging, $267,875; pound, $450; street cleaning, $65,774; culvert cleaning, $12,467; asphalt cleaning, $156,420; street watering, $8,006; street flushing, $23,361; road oil, $25,000; stable, $59,592; plant and shop, $32,542; horses, $10,500; crematory, $12,700; water, $237; rental, $1,550; inspectors' salaries, $4,800; total, $681,274.

Town of Edmonds, Burnaby, B.C.—Authority has been given the engineers to substitute six-inch for four-inch water pipes and to complete specifications and call for tenders for a supply of pipe to be laid under the 1912 waterworks by-law.

Toronto, Ont.—The experts advising the city of Toronto upon its water problem suggested in their report that a 25,000,000-gallon steam pump be added to the equipment at the main pumping station. The city engineer will bring the matter before the council.

Toronto, Ont.—The city engineer, Mr. Rust, advised the council to clean out the reservoir annually for at least two or three years, when it is hoped that the use of filtered water will render it unnecessary after that time for some years.

Victoria, B.C.—The municipal council have appointed a committee to investigate certain defects in Smith's Hill reservoir.

Victoria, B.C.—Since the first of the year the city health department has taken over the handling of street sweepings, and in consequence the quantity of refuse handled by the garbage collectors has materially increased, the amount now being daily handled aggregating some 150 loads or well over 100 tons.

Winnipeg, Man.—A committee to investigate the disposal of garbage and sewage may be formed.

BUILDINGS AND INDUSTRIAL WORKS.

Brantford, Ont.—The directors of the Brantford Roofing Company have decided to increase the plant during the coming year. At the annual meeting the directors recommended the increase of the machinery to double its present capacity, the installing of an entire new system and the addition of two new stills capable of turning out from 1,200 to 1,500 additional rolls of roofing daily.

Burnaby, B.C.—The construction of a wharf on the North Arm of the Fraser and the erection of a new stone crushing plant at an approximate cost of $12,000, are a part of the plans of the municipality of Burnaby for the year 1912.

Calgary, Alta.—The Dominion Government have decided to erect a new customs building. The building will be five stories in height and will extend the full size of the lot, 175 x 160 feet. The cost will be at least $300,000. A government architect will plan the building.

Calgary, Alta.—Announcement is made that Wood, Vallance & Adams, of Hamilton, Ont., wholesale hardware, have decided to locate a branch in this city. The firm will erect a four-storey building.

Galt, Ont.—A syndicate of Toronto and Galt financiers have formed a brick manufacturing company. The output will be 40,000 per day.

Kingston, Ont.—It is reported that the Grand Trunk Railway propose building a new passenger station in conjunction with proposed new freight sheds on the site of the hay market.

Kingston, Ont.—Proposed additions to the Canadian Locomotive Works are planned. Additional stories will be built to the present buildings, and a couple of new buildings will be started. The company contemplates spending $1,000,000 in improvements.

London, Ont.—The following is the statistical building report for the city:—

	No. of Permits.	Estimated Value.
January, 1911	27	$ 7,030.00
January, 1912	13	18,717.00

Moose Jaw, Sask.—The Prairie Oil Company, Winnipeg, Messrs. F. H. Rees & Company and Benjamin Olsen are negotiating with the municipal council regarding the erection of factories, etc.

Montreal, P.Q.—The Westmount Methodist Church will probably erect a new building at the corner of Roslyn Avenue and Sherbrooke Street. The Rev. W. E. Baker, pastor.

Niagara Falls, Ont.—The Urschel Bates Valve Bag Company of Toledo, Ohio, with branch factories in nearly all of the large cities in the United States, will install a branch at this point. The new factory will occupy what is known as the old mill property. Messrs. Hartman and Motler are representing the company.

Saskatoon, Sask.—Mr. Meyer J. Sturm, of Chicago, Ill., has been requested by the City Council to prepare plans for the new civic hospital.

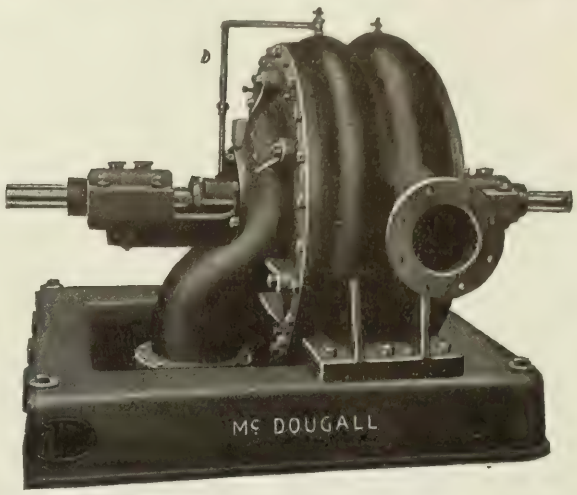
St. John, N.B.—There is a probability that a pig-iron industry may be established at this point. A mining company at present is shipping ore to points in the United States. The increased bounties, at present engaging the attention of the government, will, it is claimed, enable them to smelt the iron at a profit in Canada. The question which is now engaging their attention is whether it would be cheaper to erect blast furnaces at the mines where the shipping facilities would be limited or bring it to this port.

Worthington Turbine Pumps

The Worthington Turbine Pump is now accepted by the best engineers for all services where it is desired to deliver water against high heads. There is a limit to its application: but this limit is being continually widened by improved design, and at the present time the turbine pump is successfully employed for service where heretofore the reciprocating pump has been used exclusively.

Bulletin 110

gives a great many illustrations of these pumps driven directly by electric motors, steam turbines, steam engines and water wheels, as well as belted to the different forms of power, and will be sent on application.



Capacity 1217 Imperial or 1460 U.S. gallons per minute against 100 lbs. pressure. 150 H.P. 750 r.p.m. London, Ont.

P.O. Box 563. Full Particulars and Estimates Furnished.

Tilbury, Ont.—The Dominion Canners have issued instructions to the local management to proceed with the erection of a big addition to the local plant. The addition will be 180 by 40 feet.

Tod Inlet, B.C.—A report states that a local syndicate has completed all preliminaries toward the erection of a tourist hotel on Tod Inlet. Mr. Thos. Hooper, Victoria, B.C., architect, is drawing plans for the structure, which will have upwards of two hundred rooms.

Toronto, Ont.—The Confederation Life Association has secured a permit to build a one-story brick and steel addition to their Victoria street building, to cost $10,000.

Victoria, B.C.—Mr. H. S. Griffiths, architect, is preparing plans for an eight-story office building for the Dominion Trust Company, which will be erected on the corner of Fort and Douglas Streets.

Winnipeg, Man.—The T. Eaton Company has decided to square the present building and make a complete nine-floor structure with a frontage of 266 feet on Portage Avenue by 315 feet on Donald Street. There will also be installed five new passenger elevators and several freight elevators, two of the latter being so designed that they will carry either the delivery vans or loaded drays to the furniture floors where the loading and unloading will be done. Mr. H. McGee, vice-president, is considering estimates, etc.

Welland, Ont.—The plans of the Dominion Canning Company's plant to be erected in Fonthill, near Welland, have been issued. The main building will be three stories high, and will be used for canning tomatoes and fruit. It is expected that another large building will be put up in which corn and peas will be canned.

Winnipeg, Man.—An effort is being put forth by the members of the Anglican Church to build a cathedral near the centre of the city. It is the intention to have all the details sufficiently advanced to submit to the next meeting of the Synod in June.

BRIDGES, ROADS AND PAVEMENTS.

Kerrisdale, Point Grey, B.C.—This municipality is seeking government aid in the construction of a bridge across the deep ravine leading to the university site. It is estimated the bridge will cost in the neighborhood of $120,000.

Nelson, B.C.—A delegation waited upon the provincial government for the purpose of urging that body to construct a bridge across the Kootenay River.

Province of Ontario.—Experiments in treating clay roads with a solution of tannic acid will be conducted by Mr. W. A. McLean, provincial engineer of highways, during the coming spring and summer. This treatment will give a hardened surface to clay, rendering it tough and rubbery.

Welland County, Ont.—A report states that the good roads bill has received the official approval of the government, and will now be acted upon by the council.

York County, Ont.—Forty miles of macadam highway are to be constructed in this county. Mr. Ed. James, engineer. Tender will be found in this week's issue.

York County, Ont.—The York Highway Commission has deputed Messrs. J. J. Ward and George Henry to Ottawa with delegations from the Good Roads' Association, to wait on the Government on February 8, to ask for federal aid in the improvement of roads.

FIRES.

Halifax, N.S.—The Woodside plant of the Acadia Sugar Refining Company was totally destroyed by fire with a loss of over a million dollars.

Woodstock, Ont.—Fire damaged the Queen's and Victoria Hotels and stables to the extent of $20,000.

CURRENT NEWS.

St. John, N.B.—The Dominion Government are considering the contract for the harbor improvements at St. John, involving an expenditure of about nine million dollars. A company headed by Norton Griffiths, M.P. (Britain), is the lowest bidder in the tenders received by the late government.

Niagara Peninsula, Ont.—A report states an item for the construction of the new Welland Canal will be brought down in the House of Commons at an early date. The amount to be set aside for this work is to be $30,000,000.

Calgary, Alta.—Within the next few weeks Calgary will have one thousand new telephones in operation, and by the month of July, two thousand more will be available to customers.

Maritime Provinces.—A convention of delegates from every agricultural society, and every board of trade, the warden from each county, mayors, editors of newspapers, representatives from all farmers' and dairymen's associations, the Fruit Growers' Association, and representatives from the transportation companies, will be held in Fredericton at an early date, to discuss various means of increasing the trade of these provinces.

Winnipeg, Man.—Competitive plans for a new city hall for the city of Winnipeg will be called for shortly by the board of control.

Ottawa, Ont.—The municipal auditor is of the opinion that a purchasing agent be appointed for civic works.

LIVERPOOL DOCK EXTENSION.

The Mersey Docks and Harbor Board has decided upon a dock extension scheme, which will include a deep-water approach to accommodate vessels of 1,100 feet. The improvements, it is estimated will cost $15,000,000.

SOME RAILROAD CONSTRUCTION NOTES.

Probably the longest branch line, the Regina-Colonsay branch, of the Canadian Pacific Railway constructed last year was opened for traffic in November. The distance is 152 miles. From Regina to Colonsay it is 133 miles, while from Valeport, where the smaller branch leaves the large branch, to Bulyea, it is 19 miles. Another branch, from Outlook to Kerrobert, Saskatchewan, over 100 miles, is being constructed, and another from Weyburn and Macklin to Lethbridge. This line when completed will open a new route from Portland, Oregon, to St. Paul, Minneapolis and Chicago. From Swift Current, two branches of the Canadian Pacific Railway are being built and two branches from Wilkie.

The Canadian Northern Railway Company has spent over a million and a half dollars in improving its line between Regina and Prince Albert, a distance of about 250 miles. This line was originally known as the Qu'Appelle, Long Lake and Saskatchewan railroad, and was controlled by English capitalists and operated for many years by the Canadian Pacific Railway upon a lease which was taken over by Sir William Mackenzie when it expired in 1906.

In construction work on the Canadian Northern Railway 16,686 men are engaged. This road west of Port Arthur is operating at the present time 4,000 miles of railway. In addition, there is a line running from Fort Frances to Virginia, Minn., 98.9 miles long, controlled by the Canadian Northern. To the end of September last year 985 miles of track had been laid out of a total of 1,982 miles of new construction. It was expected that an additional 100 miles of track would be laid before the end of the year.

The Georgian Bay and Seaboard Railway of the Canadian Pacific Railway, from Victoria Harbor to Bethany Junction, Ont., was built during the year. Victoria Harbor is situated at the southerly end of the Georgian Bay, and Bethany Junction 14 miles west of Peterboro', on the present main line of the Canadian Pacific Railway, between Montreal and Toronto The length of the new line is 88 miles, 12 miles of which, from Victoria Harbor easterly to Coldwater, were completed in 1909. Work was started on the balance during the summer of 1910, and the line was opened for traffic late last year. The important towns passed through are Orillia and Lindsay. Extensive terminals are being constructed at Victoria Harbor, the yard tracks amounting in all to about 13 miles. A grain elevator has been constructed having a capacity of 2,000,000 bushels, accommodation being provided for five additional units of similar capacity.

How This Rubber Belting Cuts Production Cost

Don't let slipping belts waste power—drain away profits. Plug up the leaks—save time, money, **power,** by investigating—installing Goodyear Rubber Belting.

Goodyear Rubber Belting stands for *saved energy—economy.* Built up of plies of rubberized fabric, cured and vulcanized into the solid piece. Neither slips nor stretches. Has the cohesiveness of rubber with the enduring strength of a specially woven cotton duck fabric from which all stretch has been taken out. It is steam, water, weather and rot proof.

The same high-grade materials, the same skillful workmanship and the same years of experience that have built such famous service into the products of the Goodyear Tire & Rubber Co., U.S.A., is doing the same for Goodyear Rubber Belting and our many other rubber products.

GOODYEAR Rubber Belting

High Efficiency Belting

Every size for every purpose—1 inch to 60 inches wide—2 plies to 8 plies thick.

Goodyear Quality Belting

The highest grade made. Heaviest duck, best rubber, seamless, tough, durable. The saving main-drive belt for **Paper, Pulp** and **Lumber Mills**—for *all* mills where the horse-power transmitted is large and the demand for tensile strength is great.

Black Diamond Belting

Lighter in weight, lower in price than above, but same in *quality*. Great quantities sold to **Sawmill** trade. Hundreds of mill-owners say it gives better service than any other belt ever used.

Red Cross Belting

The ideal belt for **Thresher, Small Sawmill** and **Flour Mill** use. Built to meet competition, yet is far superior to all other third-grade belts because made of tougher rubber, heavier fabric (which means better friction) and better wearing service and cover.

Stitched Rubber Belting

We make this belting in **Quality, Black Diamond** and **Red Cross** weights for those preferring this type of belting.

Elevator Belts

We make a specialty of **Elevator Belts.** Our Leg and Lofter Belts used in hundreds of elevators. Give superior service because of greater strength. Buckets never pull out. Plies never separate. Long, efficient service guaranteed.

Conveyor Belts

For conveying crushed stone, grain, coal, ore, etc. Made in all thicknesses of face to suit requirements. Great toughness of rubber face prevents cutting and chipping; insures longest service.

IMPERIAL HIGH-SPEED FRICTION SURFACE BELT

Specially designed for planer, dynamo, generator or fan work where pulleys are small and high-speeded. If we haven't what you want in stock, we'll *make* it—and *remember*

Goodyear Rubber Belts quickly earn their cost in pains and power saved—yet they cost less than the common kind. Let our expert solve your problem. Send requirements or write for catalog to-night. In all of our business in Canada last year, we had to replace, because of slight defects, only $155.22 worth of goods.

TRADE ENQUIRIES.

The following were among the inquiries relating to Canadian trade received at the office of the High Commissioner for Canada, 17 Victoria Street, London, S.W., during the week ending January 22nd, 1912:—

A London firm of universal electrical providers and manufacturers who manufacture all classes of electrical fixtures, especially for the Canadian market, are desirous of getting into touch with actual importers in the Dominion.

A Derbyshire firm who supply large quantities of pulpstones to the Canadian market through United States agents, are anxious to get into direct communication with importers in Canada.

A London firm manufacturing a patent glass jar for preserving fruit and vegetables desire to get into touch with Canadian canners and others likely to be interested.

A firm in the English Midlands manufacturing cast-iron articles of all kinds covered with a porcelain enamel, and willing to conform to Canadian requirements, wish to hear from importers in the Dominion.

A Lancashire firm desire to find a market in Canada for Static transformers; also electric lifting tackle, such as hoist blocks, runways, light cranes, crabs, winches, etc.; and are prepared to appoint reliable agents in each province and each important business centre.

A Vancouver correspondent wishes to obtain United King goods, and construction material.

A Canadian firm of importers desire to secure the Canadian sales agency for specialties in paper manufactures such as D'Oyleys and table decorations.

A Toronto firm of grocery brokers desire to form a connection with a reliable London firm in a position to ship Ceylon and Indian teas in bulk; they are also in the market for supplies of cocoa beans and cocoa butter.

A Vancouver firm desire the agency of a United Kingdom manufacturer of cotton, cashmere, and woolen hosiery.

From the branch for City Trade Inquiries, 73 Basinghall Street, E.C.:—

A Yorkshire firm of baby carriage, toy, and steel folder manufacturers, operating several factories, desire a first-class representative in Montreal, having offices and showrooms, and possessing an established connection among stores, furnishers, etc.

A Yorkshire company manufacturing all types of steam boilers, chemical works, plant, tanks, pans, stills, heaters, etc., wish to extend their business to Canada.

A Liverpool company would be glad to receive offers from Canadian curers of dried codfish suitable for export to tropical countries.

A Montreal engineer is prepared to represent United Kingdom manufacturers of railway supplies and machinery. such as are used in connection with locomotives and rolling stock, and in railway shops.

THE BOARD OF RAILWAY COMMISSIONERS FOR CANADA.

Order No. 15819.

In the matter of the application of the Sanitaris, Limited, of Arnprior, in the Province of Ontario, for an Order directing Railway Companies to furnish, during cold weather, heated cars for the carriage of mineral water, ginger ale, and other bottled beverages, in quantities aggregating not less than carload lots, from one shipper to one or more consignees and destinations: File 18855.

Upon the hearing of the application on the 4th January last, and hearing what was alleged on behalf of the Railway Companies and the Applicant, and judgment being withheld for further information;

And upon its now appearing that Railway Companies had in practice systems of carrying way freight in heated cars; and upon the complaint of the Sudbury Brewing and Malting Company that such systems had been abandoned; and upon its appearing that at a meeting of the Canadian Freight Association, held on November 23rd, 1911, it is alleged in a circular sent to the said Brewing and Malting Company by the local freight agent of the Canadian Pacific Railway Company at Sudbury, that it was resolved that shipments in less than carload lots in heated cars should be discontinued; and its appearing that no notice of the withdrawal of such privilege had been given to shippers, and such withdrawal has worked hardship—

It is ordered that all railway companies subject to the jurisdiction of the Parliament of Canada shall forthwith reestablish the system or systems in practice by them of carrying less than carload lots in heated cars during the winter of 1910-1911; and shall forthwith grant to all shippers the rights and privileges of such shipping facilities in respect to such traffic as were in force upon their various lines during the said winter, until further Order, or until the reasonableness of the withdrawal of such facilities can be passed upon by the Board.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA.

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from The Canadian Engineer for small fee.

15815—January 19—Extending until 1st March, 1912, time for execution of Commissions and for transmission to Secretary of Board at Ottawa in connection with examination of witnesses in Dawson Board of Trade vs. White Pass & Yukon Railway in connection with Order 15719, January 2nd 1912.

15816—January 17—Authorizing G.T.P.B.L.Co. to construct spur for Yellowhead Pass Coal & Coke Co., Ltd., Alberta; from its Mountain Park Coal Branch.

15817—January 18—Approving location of C.N.O.Ry. through Twps. of Springer, Field, Badgerow, Gibbons, and Crerar, District of Nipissing, mileage 366 to 386 from Montreal.

15818—January 18—Anuthorizing town of Leamington to cross with street right-of-way of M.C.R. (Leamington & St. Clair Branch).

15819—January 18—General Order re less than carload freight to be carried in heated cars, etc.

15820—January 20—Amending Order 15741, January 3rd, 1912, that "Applicant Company install cover plates their tracks pass through the sidewalk," C.P.R. spur Swift Canadian Co., Winnipeg, Man.

15821 January 19—Approving by-law of Maine Central Railroad Co., authorizing W. K. Sanderson, G.F.A., H. D. Waldron, G.F.A., and F. S. Davis, Chief of Tariff Bureau, to issue tariffs.

15822—January 18—Authorizing International Bridge and Terminal Co. to construct its bridge and railway across Church St., Fort Frances, Ont. Crossing to be protected by gates.

15823—January 19—Authorizing C.P.R. to construct its Lacombe Easterly Branch of C. & E. Ry.), across 10 highways, and divert same, to close up portions of diversions, mileage 129.47 to 139.22, Alberta.

15824—January 20—Authorizing Vancouver, Victoria & Eastern Ry. (G.N.R.) to construct portion of tram track on Front St., Vancouver, B.C.

15825—January 19—Approving location of G.T.P. Railway station at Fitzhugh, a divisional point in Alberta.

15826—January 22—Approving location of C.N.O.R. station grounds at Portland, Ont.

15827—January 20—Authorizing C.N.O.R. to cross public road on Lot 8, between Cons. 2 and 3, Twp. of Dorion, Dist. Thunder Bay, Ont.

15828—January 23—Authorizing Twp. of Brooke, Ont., to construct McDougall Drain under tracks of Canada Southern Rly. Co., (M.C.R.)

15829—January 23—Approving location of C.N.O.R. station grounds at Dwyer Hill, Ontario.

15830—January 24—Extending until 15th February, 1912, time for erection of gates by G.T.R. at John Street, Toronto, Ontario.

15831—January 24—Extending until June 30th, 1912, time for construction of subway over Elizabeth St., Toronto Junction, Ontario.

15832—January 24—Authorizing city of Strathcona to construct a level crossing over track of C. & E. Railway, (C.P.R.), at Third Ave., North.

15833—January 24—Authorizing C.P.R. to divert highway between sections 9 and 4, at Naples Station, mileage 85.3, Napinka, S.D.

15834-35-36—January 24—Dismissing applications of city of Strathcona, Alta., for level crossings over C. & E., (C.P.R.), at 2nd Ave., North, 2nd Ave., South, and 3rd Ave., South.

15837—January 25—Approving proposed addition of C.P.R. existing bridge and change of grade across Mountain St., Montreal.

15838—January 24—Authorizing G.T.R. to reconstruct swing bridge over Rideau Canal at Ottawa.

15839—January 24—Relieving G.T.R. from further protection at Adelaide Street, at Mount Bridges, Ontario.

15840—January 24—Authorizing Government of Province of B.C. to construct highway crossing over Shuswap and Okanagan Railway (C.P.R.), one mile north of Okanagan Landing.

15841-42—January 23—Authorizing C.N.O.R. to cross public road in Lot 8, between Cons. 1 and G., Twp. of Medora, Dist. of Muskoka, and across Jane Street, Twp. of York, County of York, Ont., by means of bridge carrying highway over railway.

15843—January 23—Extending until 9th April, 1912, time for installation of bell by C.P.R. two and one-half miles east of St. Basile, County of Portneuf, Quebec.

The Canadian Engineer

An Engineering Weekly

REINFORCED CONCRETE BRIDGES BUILT OVER CURRENT RIVER, IN THE CITY OF PORT ARTHUR, ONTARIO.

BY L. M. JONES.*

The city of Port Arthur is beautifully situated on a hilly slope rising from the waters of Thunder Bay, Lake Superior. Almost through the centre of the city winds a little stream known as McVicar's Creek, while towards the northerly end of the city Current River finds its way to the lake. The banks of these two streams, as well as the surroundings, abound in the beauty of Nature, and present a pleasing view to any who have spent some time in the neighborhood.

at this time was to give street car facilities to the employees of the Western Dry Dock and Shipbuilding Company's plant, which is located north of the river and near the lake shore.

Before commencing work there was considerable discussion as to where the bridges should be located, the Board of Park Commissioners being anxious to have the bridges built alongside the Canadian Pacific Railway Co.'s bridge, owing to the fact that they were of the opinion that the extension

Fig. 1.—View Showing Deck of Both Bridges, with Swimming Pool in Distance.

The spanning of these streams with traffic bridges, both for vehicles and electric railways, has given the city engineer's department an opportunity of designing bridges to suit the required conditions in each case.

In General.—The bridges to be herein described were completed in the year 1911, and are constructed within the city park system, the one spanning Current River, the other carrying traffic over the penstocks immediately north of the river. These bridges are on the line of Cumberland Street (the main street of the city) and upon which the lines of the Port Arthur and Fort William Electric Street Railway are constructed. The chief object of constructing the bridges

of the street railway would tend to divide the park into two portions. While this was somewhat true, the difficulties of construction, and the ultimate appearance of the bridges being considered, it was decided to build the bridge on the line of Cumberland Street.

The foundations at the location decided upon were solid rock, and as the work was done at the season of the year when the water was low, no difficulty was experienced in getting in the footings. For this location the type of construction selected was the reinforced girder and slab type, supported with concrete posts resting on the footings, with retaining walls to support the embankments. As there is a dam about 1,000 feet up stream from this location, it was decided that the placing of the posts in the river-bed would be

* City Engineer of Port Arthur, Ont.

all right, as there would be no ice, driftwood, or such like to contend with. In Fig. No. 2 will be seen a general elevation of the two bridges, with roadway connecting same. It will be noticed that there is a difference between the elevations of the roadways of the bridges. The reason for this is, that it was thought best not to set the roadway elevation of the longer bridge to suit the requirements of the bridge over the penstocks, as this would necessitate a long embankment of considerable height to approach the bridge from the southerly end, and, as stated before, objections were raised to having this roadway divide the park into two portions. Also, if the bridges were kept at the same level it would make the slopes of the earth embankment extend too far into the swimming pool, shown in Figure 1, on the left-hand

Fig. 2.—View Showing General Elevation of Bridges.

side. It is the intention to make the slope as built, rather flat, and sod it, so that children using the swimming pool can also use the slope to play on.

The difference in elevation of the bridges is 6.5 feet, and the grade of the roadway connecting them is six per cent., but as the distance is short there is no apparent difficulty in operating street cars over the grade.

The bridge over the river is made up of five spans, forty feet in the clear, there being five concrete posts in each bent, ten feet on centres, these posts being twenty inches square with champered corners and reinforced with four one-inch cup bars, held together with 3/16 in. hooping at intervals of one foot. The two outside beams were 16 in. by

Fig. 3.—Showing Exterior Features of Design.

36 in., and the three inside longitudinal beams being each 24 in. by 36 in., while the transverse beams over each bent were made 20 in. by 36 in. The minimum depth of the slab is nine inches, the roadway portion being sufficiently deep at the centre to form a suitable crown for the proper drainage of water, while the street railway portion was crowned to suit the depth of rail. The deck of the bridge is provided with two sidewalks, one being five feet wide, and the other six feet wide, a driveway 18 ft. 8 in. between the curbs, and a street railway reserve suitable for single track.

It might be well to explain here that owing to lack of funds, and the small amount of traffic in sight at the present time, we were unable to construct double tracks, unless the roadway width was sacrificed, which was not thought advisable. The vehicle roadway is paved with three-inch creosoted wood blocks laid in the usual manner, with expansion joints at each curb, and at every twenty feet at right angles to the line of the roadway. The portion in the track allowance was finished with 2 to 1 cement mortar troweled to a smooth finish with proper slopes to the rain water outlets.

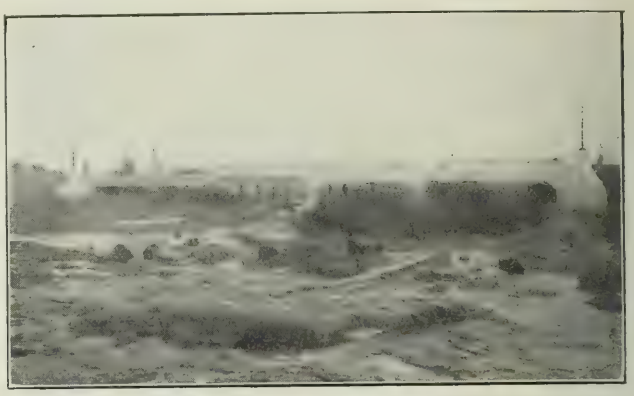

Fig. 4.—View Looking Downstream.

Overhanging the centre span on each side of the bridge was constructed a balcony 3 ft. 3 in. wide by the length of the span. These were built so that people could stand on them and view the falls above the bridge, and the scenery on the down-stream side, without interrupting the traffic on the sidewalks. The supports for these balconies were cantilevered from the main beam and covered with a slab four inches in depth. Besides providing space for sight-seers the balconies helped out in the aesthetic features of the design. The railing on the bridge is 2½-in. pipe with plain fittings, and a ball ornament on each post. Over each bent is constructed a concrete post, as part of the railing, while pedestals of larger proportions are placed at the ends of the railing to support the lamp standards. Where the pipe rails enter the concrete posts and pedestals they enter a

Fig. 5.—Bridge Over Penstocks.

pipe of large diameter set in the concrete, and in this way free ends are provided for expansion. The lamp standards are the "Luxolabra" type with five lamps on each, all lamps being 40 watt tungstens. The railing and lamp standards were all painted a deep green, and the effect is very good.

In designing the architectural features of the bridge the aim was to make all lines straight in preference to any

curved lines, and thus reduce the cost of formwork. Also, the idea being to make all surfaces as sharp and clean cut as possible.

The general features of the bridge over the penstock are similar to those of the longer bridge, the span being twenty-six feet in width. On the cross section of the bridge submitted herewith the details of the beams and slabs are fully shown. After the embankment connecting the two bridges has fully settled to a solid condition, it is the intention to connect the curbs, sidewalks, and railings on each bridge, and to finish the roadway in a permanent manner.

Cumberland Street Bridges; View of Form Work in Place.

The rails for the street cars were bedded and surrounded with concrete, being held together with tie rods at intervals of four feet. So far, and under traffic conditions, this has proved satisfactory, there being no signs of chipping or cracking of the concrete; in fact, this can be said of the entire work.

Design.—In figuring for the design of the bridges, the calculations were based on the following data:—

Live load, a thirty-ton street car, and an additional live load of one hundred pounds per square foot, with an amount for impact figured at fifty per cent. of the live load.

Ratio of modulus of elasticity of steel to that of concrete, 15.

Allowable working stress of steel in tension, 16,000 pounds per square inch.

Allowable working stress for concrete:—

(1). The extreme fibre, 750 pounds per square inch.

(2). Direct compression, 600 pounds per square inch.

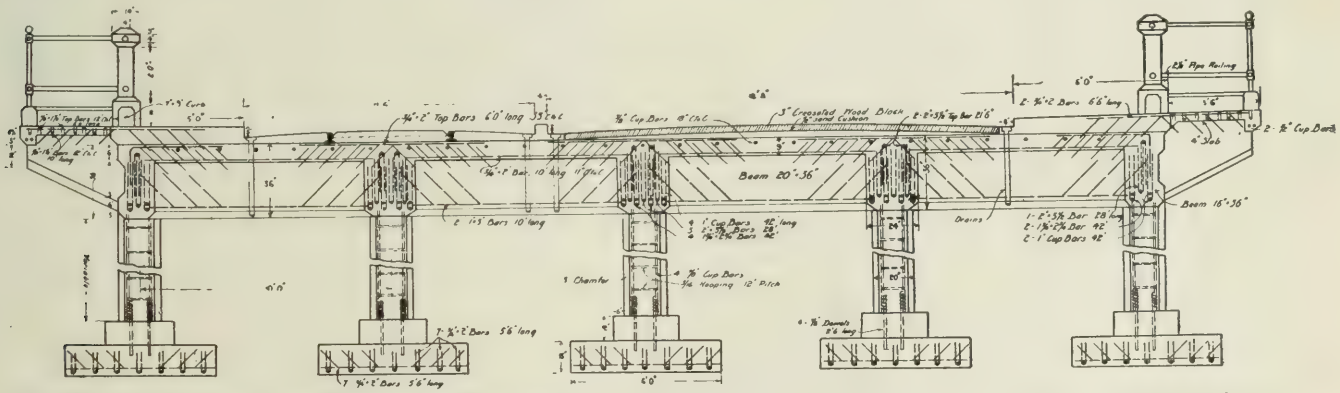
(3). Shear, 50 pounds per square inch.

Concrete.—The cement used in the concrete was Lehigh brand, Portland cement, which, when tested, had to meet the requirements of the cement specifications of the Canadian Society of Civil Engineers. The sand used was ordinary bank sand, sharp and coarse grained, with a very small percentage of loam. The broken stone called for in the specifications was crushed trap rock, of a size that would pass a one-inch ring. Shortly after the work was commenced the demand for crushed rock was so great that it was impossible for the contractor to secure any, so it was decided to use the lake shore gravel.

This gravel is found on the lake shore, about ninety miles from Port Arthur, and is admirably suited for work of this kind. In size the gravel ranges from the size of a pea up to that which will pass through a one-inch ring, the stones being of various shapes, mostly angular. As the surfaces of the stones are pitted, the cement mortar has a far better chance to bond with them than it has with ordinary gravel, and as the stone is of a granite nature the strength of the concrete was not feared by using this gravel. The proportions for the reinforced concrete were as follows: Columns, 1; 1½; 3. Slab, 1; 1½; 3. Beams, 1; 2, and 4, and for the mass concrete in wing walls and abutments, 1; 3; 5; with "plums" placed in the ordinary method. All the concrete was mixed with a "Ransome" concrete mixer. In order to obtain a good surface on the exposed faces of the bridge, the concrete mixture was of a sloppy nature, great care being taken to have the concrete well spaded and worked next to the forms. The results are very good, as may be seen in the accompanying views of the bridge.

Tenders were called for the work on July 10th, 1910, and the contract awarded to Messrs. Seaman and Penniman, of Fort William, on August 2nd. Owing to delays in securing materials the work was slow in progressing, so that it was late in the fall before the concrete work for both bridges was completed. All the forms were left on the bridge through the winter, and early in the spring of 1911 the wood blocks were laid, railing set up, and the bridges properly finished. The contractors are deserving of great praise for the work they did, their methods of working, and the diligent manner in which they attended to all the details of the form work, etc., had a good deal to do with the successful carrying out of the designs.

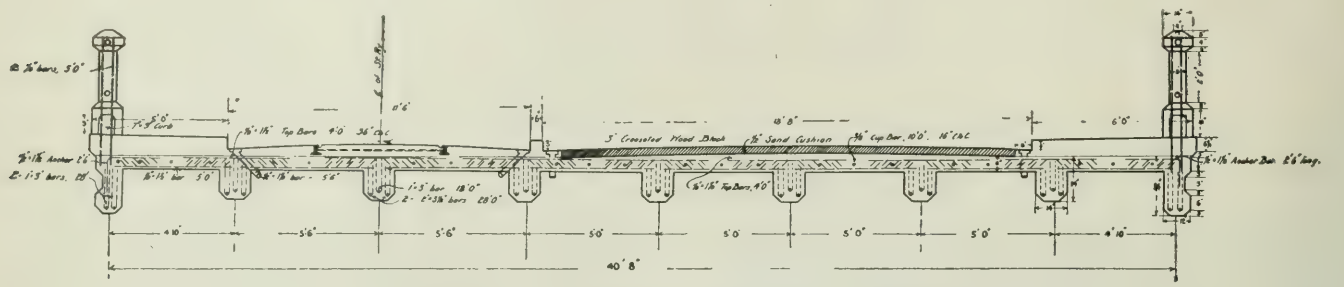
Construction.—The reinforcing steel used in the construction of the bridges was the "Kahn System of Reinforcing," and was furnished by the Trussed Concrete Steel Co., of Walkerville, Ontario. In order that contractors could tender on the same basis, as regards the reinforcing steel, the city purchased it direct and delivered it f.o.b. the site of works.



Reinforced Concrete Girder Bridge over Current River, Port Arthur. Section at Centre Span, Showing Balcony.

After the footings were set in place, the form work was commenced on the columns, girders, and abutments. The steel in the columns was then set in place, and the abutments and columns were poured to the level of the under side of girders. The forming was then constructed for the

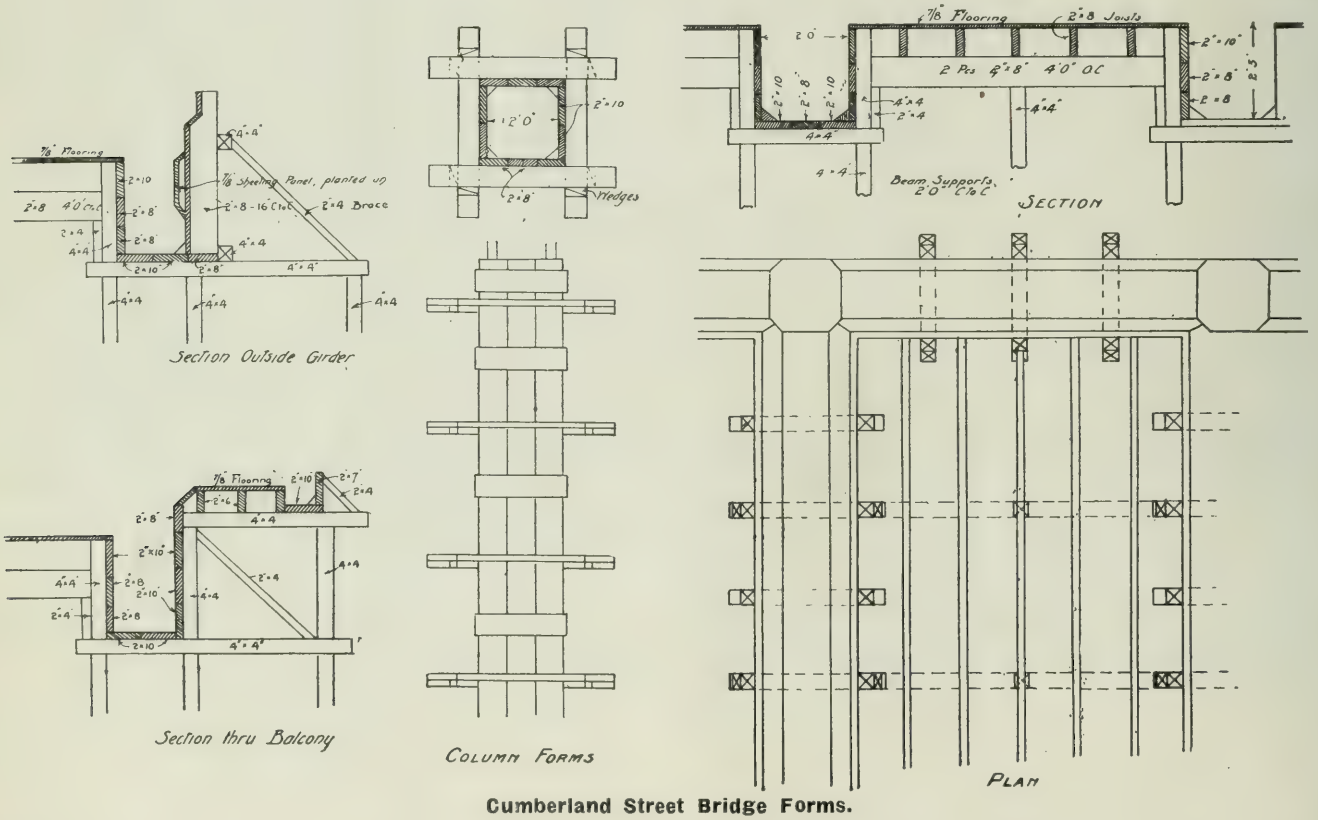
entire work on both bridges, according to the details shown in the plans presented herewith. Great care was exercised in getting the forms well braced and finished, so that all exposed surfaces would appear smooth and uniform after the removal of the forms. In this, the efforts were very successful, and good results were obtained. The forms for the long span girders were given a camber of ¾ inch at the centre of the span, to allow for any possible settlement when forms were loaded with concrete. After the work of setting forms was completed, the steel was placed in the girders, being firmly supported with wire, fastened to a 2-in. by 4-in. placed across the opening of girder forms at intervals of 3'–0. The pouring of concrete was then commenced and carried on day and night until the completion of each bridge. As stated before, the concrete was of a rather sloppy nature, and besides reasons previously stated, this was necessary as owing to the amount of steel in the beams, it was difficult to thoroughly embed it with anything but a concrete of this kind. The concrete work was commenced at one end of the bridge and finished up to the top of the slab, and continued in this way until the other end was reached, the steel in the slab, etc., being placed as the work progressed. A groove about 1½ inches in depth was left to set curb, anchors being set in this groove to further secure the curb. The curb and concrete posts were set after the concrete work on the sidewalks, roadway, and track portions was completed. Upon the completion of the whole work on the bridges, and after the forms were removed, the surfaces of concrete exposed to view were well brushed with steel brooms, and a coat of waterproofing, known as "Dry Wall" was applied. The results of the application are apparently all right, as far as can be seen at present, but it was feared at the time it was applied that the material would peel off.



Cross-Section of Concrete Bridges over Penstocks.

The cost of the bridges is as follows:—

Bridges, proper constructed in place	$17,589.98
Reinforcing steel	3,800.00
Freight and hauling steel	628.46
Lamps, including duty, wiring, etc.	585.85
Dry rock excavation	50.00
Boulder excavation	280.00
Dry earth excavation	153.40
Wet earth excavation	377.60
Rip-rap	198.20
Earth embankment	2,493.25
Sundries	223.94
Total	$26,380.68



Cumberland Street Bridge Forms.

These bridges were designed by the writer, subject to the approval of Mr. J. Antonisen, who was Commissioner of Utilities for Port Arthur at that time, while the construction of the bridges was in charge of Mr. C. E. Henderson.

SIGNALING AND INTERLOCKING.*

The author of this paper directed the attention of his audience to the signaling and interlocking systems of the new passenger terminal of the Chicago and North Western Railway Company.

When this structure had assumed a condition wherein the signaling system demanded a rigid comparison with pre-existing types, the three-position upper quadrant semaphore signal was adopted.

By the adoption of this type of signaling and the use of all three positions on the dwarf signals in the Lake Street or terminal plant, the company were able, with one signal, to give information of proceed, stop, and as to position of the signal ahead. This was deemed necessary for enginemen and trainmen in the safe handling of trains at reasonable speed, and results have shown the absolute safety and reliability of the practice. At Lake Street use was made of the third position on the last signals governing trains inbound into the depot to indicate that the track under the train shed is clear.

The dwarf signals (Fig. 1) are motor driven and, except at the Lake Street plant, all dwarf signals are used in two positions only, viz., horizontal and diagonal.

Inasmuch as the signaling and interlocking of a large terminal is installed as much for the acceleration of traffic as for its protection, the means of receiving and giving information and of communication is one of the important features, and was, therefore, given a great deal of attention, and in the solution of the problem almost everything was considered. The telegraph was dismissed from considera-

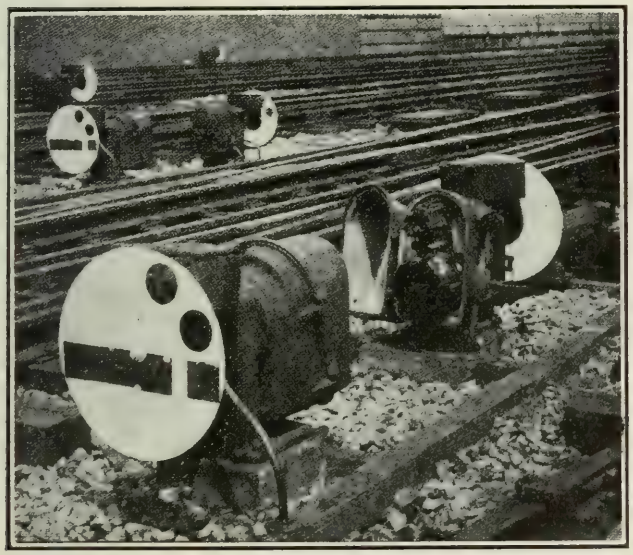


Fig. 1.

tion almost immediately, as it restricted too closely the source of supply for levermen to operate the plants and for tower directors. The various means finally adopted and used were:—

Conductors-towermen-gatemen's system of annunciators.

Telautographs.

Various forms of automatic train annunciators and indicators.

Illuminated track diagram.

Lights over levers.

Telephones.

Intercommunicating system.

* Abstracted from a paper read before the Western Society of Engineers, by J. A. Peabody.

In operating the system for through trains, the conductor pushes his butten one minute before time for his train to leave. This lights the top light on the tower director's table and the first light of the gatemen's indicators, reminding the tower director and gateman that it is nearly time for the train to leave. The tower director, if he can handle the train on time, immediately pushes his button, which action puts out the top light and lights the second one on his table, puts out the first and lights the second one at the gate, and lights the top light of the conductors' indicators. When it is time for the train to leave, the gateman closes his gates, and after waiting for the last passenger who went through the gate to get on the train or at least giving him sufficient time to do so, he pushes his button. This puts out the second light at the gate, puts out the top light and lights the lower one of the conductors' lights, and

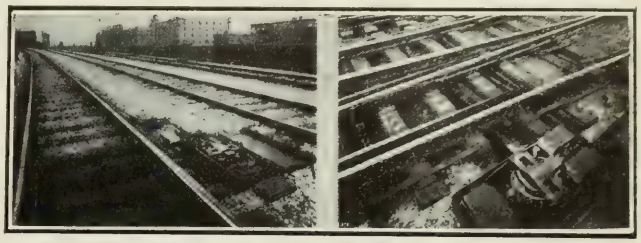

Fig. 2a. **Single Switch.**

Fig. 2b. **Double Slip Switch.**

puts out the second and lights the third of the tower directors' lights, thus advising the conductor and tower director that the train may leave. The conductor then, and not until then, gives the engineman the signal to proceed, which he does, provided the proper interlocking signal indicates that he may. The restoring of the first interlocking signal to the stop position automatically restores the system to its normal condition ready for the next move.

For giving information from one tower to another of a train move and something as to its character, a push button scheme was developed which has been named the "Intercommunicating System."

The indication on these boards is made by small telephone lamps arranged in horizontal rows and columns. The columns represent the track numbers, and the rows the various classification of trains. The boards were made to suit local conditions and are entirely of standard telephone apparatus.

The method of connecting the switch movements to the switches, movable point frogs, and derails is clearly shown in Fig. 2 a. b. The General Railway Signal Company's standard No. 4 movement was used for everything except derails, for which their standard No. 2 movement was used.

No detector bars were employed on the switches, derails, etc., of the Lake and Clinton Street plants, detector circuits only being relied on to protect against the throwing of these functions under trains. In the other three plants, where the speed of trains is on an average much higher, both detector bars and detector circuits are employed. When detector bars were not used with the No. 2 movement, a spring was applied on each movement to take its place in insuring that vibration would not operate the movement sufficiently to unlock the derails if the control circuit were broken.

The track circuits used as detector circuits were made as long as possible consistent with operating conditions, in order to cut down as much as possible the total number of track circuits required and also in a measure provide against slow-acting relays.

Continuous rail insulated joints were used. The switch rods are insulated and the switch tie plates cut so as to

leave a space of not less than two inches between the ends, as experience, covering a period of several years, demonstrated that the strength of a continuous plate between two rails is not required; also, the cut plate is much cheaper both in first cost and maintenance and can be inspected for insulation without difficulty.

The operating switchboard, the circuits of which are shown in Fig. 3, contain the main protection used for the interlocking apparatus.

The power wires from the main power switchboard pass through this board to the interlocking machine. The ammeter is inserted in the positive wire. By means of this ammeter the leverman may watch the current used to operate the switches and signals, and can tell whether they are working properly.

At Lake and Clinton Streets, several ammeters are placed on the turret of the interlocking machine.

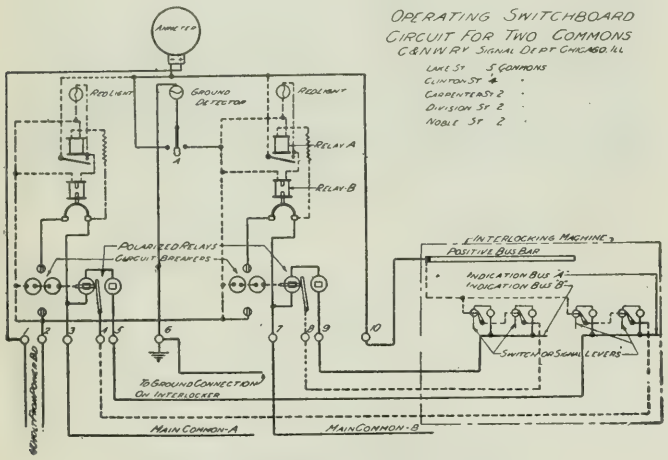

Fig. 3.—Circuits-Operating Board.

The track circuits for the interlocking plants are fed by means of loops from 20-volt storage batteries located in the towers. Two positive and two negative wires are run from the low voltage distributing board to the junction boxes in the section of the plant to be fed. The wires of the same polarity are joined at the end, thus forming loops so that current from the switchboard has two paths to any point on the loop. The loop wires can break at any place, and every point would still receive current.

On the switchboard, ammeter jacks are placed for each wire and again for the main feed wires after the loop wires have joined. A regulating rheostat is inserted in the positive lead capable of cutting the battery down to about 12 volts, at which point it is generally maintained. The track sections are fed from various points on the loop through resistance units placed on each side. These are in most cases 37.5 ohms, although on some sections the resistance has been reduced on one side to meet local conditions. These resistances are of the enclosed fuse type mounted on the terminal boards of junction boxes and manholes. During wet weather, when the leakage between rails increases, the rheostat may be used to allow more current to flow to compensate for this leakage. The purpose of the ammeter jacks is to determine when a break occurs in any of the loop wires. As long as the circuits are perfect the readings are the same, while if there is a break the readings on the No. 1 and 3 wires will be different from the readings on the No. 2 and 4 wires respectively.

In calculating the size of the wire for the loops, one side of each loop was considered cut off at the switchboard and every track circuit occupied except the one nearest the cut-off end.

The voltage required on this last track circuit must be enough to pick up its relay. The voltage on the switchboard being 12, the current used by each shunted track circuit being known, the size of wire is easily worked out. The practical limit to the number of track circuits that could be fed from a loop was found to be 20. Relays of 12 ohms are used on all circuits fed from the track circuit loops. A 12-ohm resistance unit is located in series with the relay to obtain a quick drop-away of the armature, the time being reduced 50% by the insertion of this resistance. This is very desirable on account of the detector locking.

Where the track sections are adjacent to the towers the track relays are located in the tower, but where they are too far away for efficient operation, repeater relays are placed in the tower and controlled by the track relays which are placed adjacent to the track sections.

For the train-shed track circuits two 110 volt to 20 volt direct current to direct current motor generator sets were installed in a relay room under the station platform. These feed direct to the tracks, no storage battery being used, and the sets are run successively in six hour periods.

These motor generator sets are run off the depot lighting system, and by using them instead of a rheostat, the lighting circuits and track circuits are kept separated, and any grounds which may occur on one will have no effect on the other.

At tthe signal bridges at which power-houses are located, the track circuits are each fed from a single cell of 120 ampere hour capacity storage battery with an 8-ohm resistance in series. Relays of 4 ohms are used where the track circuit is fed from these individual cells.

The release route locking circuits operate as follows:—A train entering a route locks up all switches, derails, and movable point frogs in the route, and when the train leaves each track section, all switches, derails, and movable point frogs in that section are released so that they may be moved.

This result is accomplished as follows: The circuits are divided into two general classes—the stick relay circuits and the lock circuits. The stick relay circuits are composed of the stick relay pick-up and the stick relay stick-up wires. The lock circuits are composed of the battery feed wire and the lock wire. The direction in which the locking takes effect is determined by the position of the stick relay, the relay being up when the train is going in one direction and down when going in the other. The relay is picked up by a contact on the sigal governing in the direction requiring the relay up, and is then held up by back contacts on the track relays in the route. The signal in the opposite direction does not pick the stick relay up and consequently it remains down. It will be readily seen that restoring one signal to normal position and clearing the opposing signal will reverse the route locking. This is valuable for switch-engine moves and also for those trains which are too long to completely enter the station and clear the last switch circuits of the interlocking plant.

The levers are controlled by electric locks located on top of the lever, the circuit being held normally open by a contact operated by the lever latch. A white light is in multiple with the lock and latch contact, showing at all times whether the lock can be energized or not. Each lock is controlled directly by the track relay of the section in which the switch is located, thus providing absolute detector locking, making it impossible to operate a switch lever, and therefore the switch, when the section in which that switch is located is occupied. The lock wire receives battery from a back contact of the stick relay while battery is fed to the other end of the route over the battery feed wire, when the stick relay is energized, through the front point of the relay. Thus it will be seen that when a train is going

in the direction that the stick relay is energized, battery is fed behind the train as it proceeds. When the train is proceeding in the opposite direction, the stick relay being de-energized the current is also fed from behind the train. The switches and derails by this means are always locked ahead of and under the train while those which are behind the train are unlocked. In case it becomes necessary to change a switch or derail ahead of a train which has come to a stop, current may be supplied to all locks in the route except those under the train by means of a push button so located in the tower that it requires one man to operate it while the leverman is operating the lever, thus bringing two men into operation.

On account of the number of circuits, requiring a great mass of wires, it was necessary to do the work mechanically, i.e., furnish detailed plans showing exactly how each piece of work was to be done, the workmen being required to follow these plans without any knowledge of the circuits involved.

Terminal board plans were made for every junction box and manhole, showing the wires to be spliced through, the wires to go to terminals, the location of terminals and resistance units.

In the same way, plans were made of terminal boards for junction boxes on signal bridges and for those located in the towers.

Plans of the conduits were made, showing location and size of each. Tables were furnished showing the number and size of wires in each duct, the total length of each wire, and the number of feet to be left out at each end. The number of each wire and its destination was also shown.

Plans were then furnished of the back of the relay racks, the combination board, interlocking machine proper, the release buttons, etc., showing the details for connecting the wires and using the tag numbers described above to identify them.

The circuit sheets were written instead of drawn, and by description or number gave each connection to be made and each cable or conduit through which a wire ran. This work of the drafting room saved an immense amount of work in the field.

The motor-generator set provided for charging the storage batteries is located at the signal bridges.

The batteries being in duplicate, each set of battery has a charging switch so arranged that the load is never deprived of battery. The switch is constructed so that either set of battery may be discharged with the other on open circuit or being charged. In accomplishing this result and to avoid short-circuiting the battery a resistance is inserted in the circuit in the intermediate positions. All charging switches on the switchboard are arranged in series so that any number may be cut in at the same time. The voltage of the generator is adjusted for the number of cells being charged. Terminals are provided for connecting in a portable voltmeter ammeter.

To provide for the possibility of the alternating current failing or a fuse opening in the motor end, a three-phase 220-volt relay is used, operated in parallel with the motor controlling the charging circuit. Whenever the power fails or a motor fuse opens up, this relay opens the charging circuit preventing discharge of the battery. If the power returns, after failing, the relay picks up again and restores the charging circuit. As it picks up before the motor has reached full speed, the battery current runs the generator end as a motor and aids in bringing the set up to speed without excessive overloading.

THE DESIGN OF TALL CHIMNEYS.*

(Continued from last week).

Centre of Wind Pressure.—Let h = height from bed joint to centre of gravity of diametral plane, which will be the centre of wind pressure, H = whole height of portion, D = lower diameter, and d = upper diameter, then—

$$h = H \times \frac{D + 2d}{3(D + d)}, \text{ and } p = \frac{W(\frac{1}{2}D - l)}{hH\frac{1}{2}(D+d)}$$

For rapid proof we may apply this to the square pier,

thus, $p = \frac{270(\frac{1}{2} \times 3 - 1)}{15 \times 3 \times 30} = 0.1$ cwt. $= 11.2$ lb. as before.

When Tension is Permissible.—When tension is permissible on the inner edge the wind pressure may be increased, so that the resultant is forced nearer to the overturning edge. The maximum pressure will, under these circumstances, be $K\left(\frac{W}{A} + \frac{l}{4D}\right)$ and the minimum, or tension, $k = \frac{W}{A} - \frac{6l}{D^2}$

Air and Combustion.—There are now some interesting points to note with regard to the use of the chimney. With air at 60 deg. Fahr., 30-in. bar., about 13 cu. ft., weigh 1 lb., and 12 lb. of air (156 cu. ft.) are required to combine with the constituents of 1 lb. of coal for perfect combustion, but to allow for working conditions it is necessary to provide 24 lb. (312 cu. ft.), which is equal to 700,000 cu. ft. of air per ton of coal. Putting it in another way, the air and smoke together, at a temperature of, say, 300 deg. Fahr.,

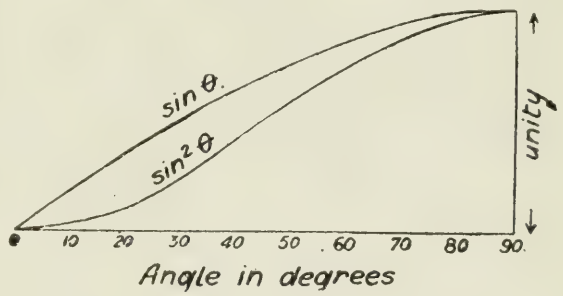

Fig. 5.

equal about 2,000 cu. ft. per cubic foot of water evaporated. The maximum economical draught for boilers is that arising from, or equivalent to, the pressure due to ½-in. head of water, causing a consumption of about 36 lb. coal per hour per square foot of fire grate area. The temperature of combustion in the furnace is about 2,400 deg. Fahr. The temperature of the gases is generally ascertained by hanging strips of metal foil in the flues on an iron wire, and noting which are melted by the heat—viz., copper 2,000 deg., aluminum 1,800 deg., zinc 750 deg., lead 630 deg., tin 440 deg. A 3-in. cast-iron pipe is sometimes built in the base of the chimney for the purpose of introducing these test pieces or a pyrometer, or for testing the suction. The temperature may be as low as 300 deg. Fahr., with any Cornish or Lancashire boilers, or as high as 1,000 deg. Fahr. with water tube boilers. At 600 deg. Fahr., which is about the usual temperature of the escaping gases, the volume of air entering the furnace is doubled on exit.

Chimney Draught.—The force of the draught in a chimney stack is the deficiency of weight of the column of rarefied air in the chimney compared with a similar column of the external air. The velocity in feet per second is, roughly, two and a half times the square root of the height in feet. As regards smoke prevention, there are several patents on the market, but a good stoker is the best smoke preventer.

Horse Power of Chimney.—The horse power of a chimney is sometimes spoken of. For a round chimney the following rules have been given:—

(1) $H.P. = 3\frac{1}{3}\ (\text{area sq. ft.} - 0.6\sqrt{\text{area}}) \times \sqrt{\text{height ft.}}$

(2) $H.P. = 2\frac{1}{2} \times \text{diam. ft.}^2 \times \sqrt{\text{height ft.}}$

(3) $H.P. = \dfrac{\text{diam. in.}^2 \times \sqrt{\text{height ft.}}}{70}$

(4) $H.P. = \dfrac{\text{diam. in.}^3}{300}$

but one would have supposed there were enough variations of horse power without introducing another.

APPENDIX.

Design for Chimney.—In order to emphasize the author's description, he now proposes to design a circular chimney for four Lancashire boilers, each having two furnaces, 2 ft. 9 in. wide × 6 ft. long, burning 12 lb. coal per square foot of firegrate per hour, and evaporating 9½ lb. water per pound of coal. The boilers themselves are 7 ft. 6 in. diameter × 30 ft. long, with Galloway tubes, and supply steam to an engine of 750 I.H.P.

Total firegrate area = $4 \times 2 \times 2.75 \times 6 = 132$ sq. ft.

Consumption of coal per hour $132 \times 12 = 1{,}584$ lb.

Consumption per week of fifty-six hours $\dfrac{1{,}584 \times 56}{2{,}240} =$ 39.6, say 40 tons.

Water evaporated per hour = $1{,}584 \times 9.5 = 15{,}048$ lb. = 1,504.8 gallons.

Water used per I.H.P. per hour $= \dfrac{15{,}048}{750} = 20.064$, say 20 lb., which fairly represents modern practice with compound condensing engines.

Area of main flue $\dfrac{132}{8} = 16.5$ sq. ft., say 3 ft. wide × 5 ft. 6 in. high, invert, say 4 ft. below ground level.

Height of Chimney:—

(a) From coal consumption, scaling from diagram, 40 tons per week = 140 ft. high.

(b) From length of flues, chimney being 28 ft. from further boiler. Three times length of boiler + twice length of main flue = $3 \times 30 + 2 \times 28 = 146$, but there is something inviting about round numbers, so that 140 ft. may be decided upon as the height above ground level, or 150 ft. in all.

Sectional Area of Chimney:—

(a) From coal consumption $= \dfrac{1{,}584}{112} = 14.14$ sq. ft.

(b) From firegrate area $= \dfrac{132}{10} = 13.2$ sq. ft.

(c) From indicated horse power (I.H.P.) of engine $= \dfrac{750 \times 2\frac{1}{2}}{144} = 13.02$ sq. ft.

(d) From coal consumption and height $= \dfrac{1{,}584}{12\sqrt{150}} = 10.8$ sq. ft.

(e) From firegrate area and height $= \dfrac{132}{1.5\sqrt{150}} = 7.18$ sq. ft.

An allowance of 14 sq. ft. should therefore be ample without any further allowance for friction. Reference to a table of areas shows that 4 ft. 3 in. diameter = 14.18 sq. ft. area, which may be decided upon as suitable.

Height of firebrick lining, $\dfrac{150}{5} + 10 = 40$ ft.

SKETCH SECTION.

Data.—Main flue 5 ft. 6 in. by 3 ft., invert 4 ft. below ground level. Chimney 140 ft. high, 4 ft. 3 in. least internal diameter. Lining 40 ft. high, 20 ft. of 9-in. thick and 20 ft. of 4½-in. vertical. Batter not less than 2½ in. in 10 ft.

Least permissible outside diameter at ground line $\dfrac{140}{12} = 11$ ft. 8 in. Thickness of shaft, say, 20 ft. of 1 brick, 20 ft. of 1½ brick, 20 ft. 2 brick, 20 ft. of 2½ brick, 20 ft. of 3 brick, 20 ft. of 3½ brick, 20 ft. of 4 brick, remainder of 4½ brick. Projection of cap 9 in.

The diameter at ground line requires to be 2/3′ 4½″ + 2/1½″ + 2/9″ 4′ 3″ = 12′ 9″. The diameter at top requires to be 2/9″ + 4′ 3″ = 5′ 9″, which fortunately gives the round number of 7 ft. for taper, or 3′ 6″ batter on each side = 42 in. in 140 ft. $= \dfrac{42}{14}$ ins. in 10 ft. = 3 in. in 10 ft., or each 20-ft length increases 1 ft. in diameter.

If the upper half of the firebrick lining stands central on the lower half, the clearance at top of former will be found thus: $\dfrac{36}{10} \times 3 = 10.8$ in. batter, $10.8 \times 2 = 21.6$, say 1′ 9½″ taper, reduced outside diameter 12′ 9″—1′ 9½″ = 10′ 11½″. Inside diameter of shell = 10′ 11½″—2/2′ 7½″ = 5′ 8½″. Outside diameter lining = 4′ 7½″ + 2/4½″ = 5′ 4½″. Clearance = ½ (5′ 8½″—5′ 4½″ = 2 in. at top of firebrick lining to be covered by oversailing course projecting, say, 4 in., and with clearance above top of not less than $\dfrac{40}{5} \times \frac{1}{8}$ = 1 in. to allow for expansion.

The clearance outside lower length of firebrick lining at junction with upper length will be $\dfrac{16}{10} \times 3 = 4.8$ in. batter, $4.8 \times 2 = 9.6$ in., say 9½-in. taper, reduced outside diameter 12′ 9″—9½″ = 11′ 11½″, inside diameter of shell = 11′ 11½″—2/3′ 0″ = 5′ 11½″. Outside diameter of lining = 4′ 3″ + 2/9″ = 5′ 9″. Clearance = ½ (5′ 11½″—5′ 9″) = 1¼ in., which will be satisfactory, but before the design is proceeded with further the stability should be calculated.

Calculation of Stability.—The first step in calculating the stability is to determine the weight of each portion between the various set-offs. Suppose the material to be picked stock bricks laid in lias mortar, the weight may be taken at 112 lb. per cubic foot.

Weight of Each Length.—

$$\text{Top length} = \pi h t \left(\frac{D + d + \sqrt{Dd}}{3} - t \right) \times 112 = 3.1416 \times 20 \times 0.75 \left(\frac{5.75 + 5.75 + \sqrt{6.75 \times 5.75}}{3} - 0.75 \right) \times 112 = 47.124 \times 5.493 \times 112 = 28991.5 \text{ lb.}$$

2nd length	=	48371.68 lb.
3rd "	=	71147.44 lb.
4th "	=	97148.08 lb.
5th "	=	126509.60 lb.
6th "	=	159230.40 lb.
7th "	=	195096.16 lb.

Weight Above Each Set-Off.—The weights will be required in totals above each set-off; they may therefore be collected as follows:—

1st set-off	.....	=	28991.50
2nd "	28991.50	+	48371.68	= 77363.18
3rd "	77363.18	+	71147.44	= 148510.62
4th "	148510.62	+	97148.08	= 245658.70
5th "	245658.70	+	126509.60	= 372168.30
6th "	372168.30	+	159230.40	= 531398.70
7th "	531398.70	+	195096.16	= 726494.86

Areas of Bed Joints.—The next step is to find the sectional area at the lower end of each portion—i.e., the bearing surface at each set-off—viz., $A = \frac{\pi}{4}(D^2 - d^2)$, d being now inside diameter.

1st set-off	.7854	$(6.75^2 - 5.25^2)$	= 12.74
2nd "	.7854	$(7.75^2 - 5.50^2)$	= 12.74
3rd "	.7854	$(8.75^2 - 5.75^2)$	= 34.16
4th "	.7854	$(9.75^2 - 6.00^2)$	= 46.34
5th "	.7854	$(10.75^2 - 6.25^2)$	= 60.08
6th "	.7854	$(11.75^2 - 6.50^2)$	= 75.20
7th "	.7854	$(12.75^2 - 6.75^2)$	= 91.84

Mean Pressure.—The mean pressure due to the direct load will also be required at each set-off—viz., $m = \frac{W}{A}$,

1st set-off $\frac{289991.5}{12.74 \times 2,240}$ = 1.01 tons per sq. ft.

2nd "	.....	= 1.45	"	"
3rd "	.....	= 1.91	"	"
4th "	.....	= 2.34	"	"
5th "	.....	= 2.79	"	"
6th "	.....	= 3.16	"	"
7th "	.....	= 3.53	"	"

Moduli of Section.—The modulus of section corresponding to each of these sectional areas—viz., $Z = \frac{\pi}{32}\left(\frac{D^4 - d^4}{D}\right)$ d being inside diameter, will be—

1st set-off $0.101 \left(\frac{6.75^4 - 5.25^4}{6.75}\right)$ = 19.65

2nd "	.....	= 35.10
3rd "	.....	= 55.20
4th "	.....	= 80.42
5th "	.....	= 111.43
6th "	.....	= 148.91
7th "	.....	= 185.28

Height of Centre of Wind Pressure.—The height of centre of wind pressure—i.e., centre of gravity of diametral plane—above each set-off—viz., $h = H \times \frac{D + 2d}{3(D + d)}$, d being top diameter, will be—

Above 1st set-off $20 \times \frac{6.75 + 2 \times 5.75}{3(6.75 + 5.75} = 9.73$

" 2nd "	$40 \times \frac{7.75 + 2 \times 5.75}{3(7.75 + 5.74}$	= 19.00
" 3rd "	.....	= 28.00
" 4th "	.....	= 36.50
" 5th "	.....	= 45.40
" 6th "	.....	= 53.64
" 7th "	.....	= 61.74

Width at Centre of Pressure Above Each Set-Off.—This will be given by the formula $w = D - \frac{h}{H}(D - d)$, where h height of c.g. of diametral plane above set-off, H = whole height above ditto, D = diameter at set-off, d = diameter at top.

1st set-off $6.75 - \frac{9.73}{20}(6.75 - 5.75) = 6.75 - \frac{9}{20} \times .487 = 6.26$

2nd "	.....	= 6.80
3rd "	.....	= 7.36
4th "	.....	= 7.92
5th "	.....	= 8.48
6th "	.....	= 9.07
7th "	.....	= 9.67

Wind Pressures.—The wind pressure on each portion, according to the formula from which the table is constructed, will be $\log p = 1.125 + 0.32 \log (h+g) - 0.12 \log w$, where g is height of set-off in question above ground line, and h centre of pressure as in last paragraph.

Above 1st set-off, $\log p = 1.125 + 0.32 \log (129.73) - 0.12 \log (6.26)$
$= 1.125 + 0.32 (2.1130404) - 0.12 (.796574)$
$= 1.125 + .6761729 - .095588$
$= 1.7055840$
$\therefore p = 50.76$

Above 2nd set-off	"	= 48.89
" 3rd "	"	= 47.10
" 4th "	"	= 45.22
" 5th "	"	= 42.83
" 6th "	"	= 40.50
" 7th "	"	= 38.00

Area of Diametrical Planes.—The areas of the diametrical planes above each set-off will be $d = \frac{1}{2}(D+d)H$, where D = diameter at set-off, d = top diameter, H = whole height above set-off.

1st set-off	$= \frac{1}{2}(6.75 + 5.75)20$	= 125	sq. ft.
2nd "	$= \frac{1}{2}(7.75 + 5.75)40$	= 270	"
3rd "	$= \frac{1}{2}(8.75 + 5.75)60$	= 435	"
4th "	$= \frac{1}{2}(9.75 + 5.75)80$	= 620	"
5th "	$= \frac{1}{2}(10.75 + 5.75)100$	= 825	"
6th "	$= \frac{1}{2}(11.75 + 5.75)120$	= 1,050	"
7th "	$= \frac{1}{2}(12.75 + 5.75)140$	= 1,295	"

Bending Moment Due to Wind Pressure.—The bending moment due to wind pressure above each set-off, taking coefficient for circular chimney as

$\frac{\pi}{4}$, will be $\frac{\pi}{4} p a h$.

1st set-off $\frac{.7854}{} \times 50.76 \times 125 \times 9.73$
$= 18.52$ ft.-tons.

2nd " $\frac{.7854}{} \times 48.89 \times 270 \times 19.00$
$= 75.24$ ft.-tons.

3rd "	= 172.10	ft.-tons.
4th "	= 307.48	"
5th "	= 481.25	"
6th "	= 683.80	"
7th "	= 911.46	"

Stress Due to Bending Moment.—The stress due to bending moment only will be $\frac{M}{Z}$, thus:—

1st set-off $\frac{18\cdot52}{19\cdot65} = 0\cdot94$ tons per square foot.

2nd " $\frac{75\cdot24}{35\cdot10} = 2:14$ " "

3rd " $\frac{172\cdot10}{55\cdot20} = 3\cdot11$ " "

4th " $\frac{307\cdot48}{80\cdot42} = 3\cdot82$ " "

5th " $\frac{481\cdot25}{111\cdot43} = 4\cdot31$ " "

6th " $\frac{683\cdot80}{148\cdot91} = 4\cdot60$ " "

7th " $\frac{911\cdot46}{185\cdot28} = 4\cdot91$ " "

Maximum Pressures.—The maximum compression on the leeward edge of chimney at each set-off under the full theoretical wind pressure may now be obtained by the formula $K = m + \frac{M}{Z}$ and the tension on the inner edge $k = m - \frac{M}{Z}$

			Tons per sq. ft.
1st set-off	1.01 + 0.94 = 1.95	comp.,	0.07 comp.
2nd "	1.45 + 2.14 = 3.59	"	0.79 tens.
3rd "	1.91 + 3.11 = 5.02	"	1.20 "
4th "	2.34 + 3.82 = 6.16	"	1.48 "
5th "	2.79 + 4.31 = 7.10	"	1.52 "
6th "	3.16 + 4.60 = 7.76	"	1.44 "
7th "	3.53 + 4.91 = 8.44	"	1.38 "

The safe load on the material according to the limits laid down being 8 tons per square foot, the result shows a trifle over, but not sufficient to necessitate any alteration in the design.

Cap and Base.—No account has been taken of the weight of cap nor of the extra surface it exposes to the wind, but the effect of these will be so slight that the stability will not be affected thereby. The part immediately above ground will usually be in the form of a square pedestal externally, with cornice, plinth and base; this will add considerable sectional area at the lowest set-off, reducing the maximum pressure, but increasing the whole load on foundations.

No Tension on Inner Edge.—If tension is not to be permitted on the inner edge then we must find the maximum wind pressure permissible by the formula $l = \frac{3D^2 - d^2}{8d}$ (d being inside diameter) and $p = \frac{W(\frac{1}{2}D - d)}{hH\frac{1}{2}(D+d)}$ (d being top diameter).

Then $l = \frac{3 \times 12\cdot75^2 - 6\cdot75}{8 \times 12\cdot75} = 4\cdot33456$ and

$p = \frac{726494\cdot8604 \times 12\cdot75 - 4\cdot33456)}{61\cdot74 \times 140(12\cdot75 + 5\cdot75)} = 18\cdot54$ lb. per square foot as the mean effective pressure over the whole area, but being cylindrical, the equivalent normal pressure on a plane surface would be $\frac{18\cdot54}{0\cdot7854} = 23.6$ lb. per square foot, or, according to Rankine's coefficient, $\frac{18.54}{0.5} = 37$ lb. per sq. ft.

Summary.—It will thus be seen that, unless extraordinary means are taken to secure stability beyond the allowances that have been made in the design, a wind pressure varying from 38 lb. to 50.76 lb. per square foot will cause a maximum compression of 8.44 tons per square foot and a maximum tension of 1.52 tons per square foot, both being within the safe limits of the material, but that if no tension is to be allowed on the inner edge the wind pressure must not exceed an average of 23.6 lb. per square foot, or 37 lb.

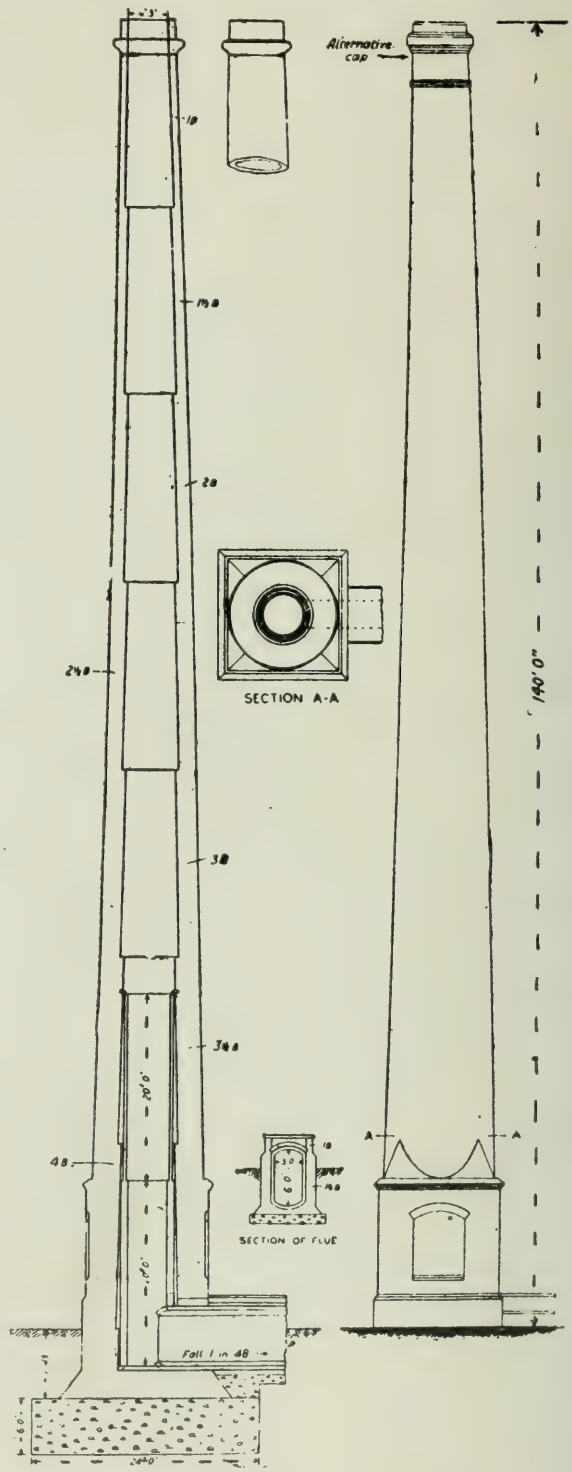

Fig. 10.
Design Accompanying Prof. Henry Adams' Paper on "Tall Chimneys."

(according to the coefficient taken), against a normal plane surface.

Prof. Unwin says (in "Bridges and Roofs," p 119): "We are in this country visited annually by gales, singularly constant in their maximum force, amounting to from 20 lb. to 25 lb. per square foot, on a surface perpendicular to their direction. More rarely cyclonic storms sweep over the country, during which still higher pressures are registered. A pressure of 30 lb. was registered during the Royal Charter storm; one of 33½ lb. was observed at Greenwich in the storm preceding the fall of the station roof at Manchester. Higher pressures still, up to as much as 55 lb., have been recorded at various times, but the accuracy of these observations is more doubtful. We shall probably allow margin enough for the worst contingency if the maximum pressure of the wind is assumed at 40 lb. per. square foot of a surface perpendicular to its direction.

Concrete Base.—The size of the concrete base will depend to some extent upon the nature of the soil, but it must be wide enough to avoid any risk of tilting under maximum wind pressure. This may be calculated as follows, assuming the concrete base to be 24 ft. square and 6 ft. deep—

Weight of shaft	.....	726,495. lb.
" plinth, say	....	83,628 "
" footings, say.		163,632 "
" concrete, say.		414,720 "
		1,388,475 " = say, 620 tons.

Then $m + \frac{M}{Z} = \frac{620}{24 \times 24} + \frac{911.46}{\frac{1}{6} \times 24^3} = 1.472$ tons per square foot maximum compression, and 0.681 tons per square foot minimum compression on the earth below the concrete.

Protection from Lightning.—The lightning conductor should consist of a coronal or copper band round the top of chimney, with copper needles, 6 in. long, fixed at intervals of 3 ft. or 4 ft., the points being platinized, gilded, or nickled, to prevent corrosion. The main conductor should be not less than 1 in. × ¼ in., securely attached to the coronal by a clean metal-to-metal connection, and be carried down side of shaft without insulation, but held by projecting holdfasts and clips every 4 ft. to 6 ft. The lower end should be carried down 2 ft. under the ground and 10 ft. away from the base, riveted and soldered to a sheet of copper 4½ sq. ft., area, 1/16 to ⅛ in. thick, and embedded in moist earth or coke-breeze. A tube well, as adopted by Mr. Killingworth Hedges, forms the best earth terminal when there is any doubt about the moisture round the copper being permanent.

Completion of Design.—The design may now be completed as shown.

Cost of Chimney.—The cost of building a tall brick chimney shaft is approximately 1s. 3d. to 1s. 6d. per cubic foot of the solid materials, labor alone being 4d. to 6d. per cubic foot, but much, of course, depends upon locality, quality of materials, and cost of labor.

Classification of Wind Force.—The classification by different writers of the force of the wind varies considerably. The following is a fair average:—

Description.	Velocity in miles per hour.	Approximate corresponding pressure lb. per sq. ft.
Barely perceptible wind ..	2½	1/32
Light breeze	5	⅛
Pleasant breeze	7½	¼
Good breeze	10	½
Strong breeze	15	1⅛
High wind	20	2
Half gale	30	4½
Strong gale	40	8
Whole gale	50	12½
Great storm	60	18
Hurricane	80	32
Violent hurricane	100	50

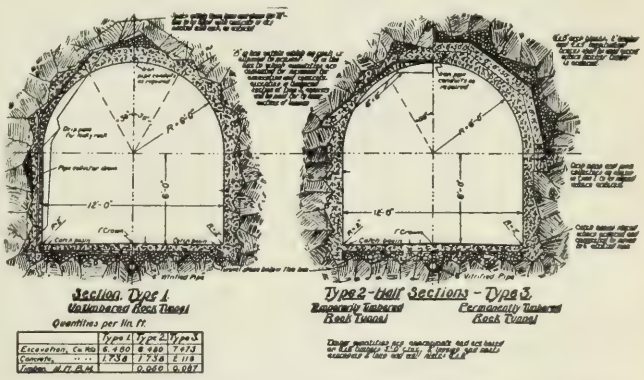
By Smeaton's formula $p = \frac{V^2 \text{ miles per hour}}{200}$

Alphons Custodis Chimneys.—The Alphons Custodis Chimney Construction Company have built a large number of tall chimneys in America and England, their specialty being radial perforated bricks, which appear to have every advantage but that of weight. Weight being one of the elements of stability, its reduction can only be compensated for by increase of one or more of the other elements, such as batter of shaft, diameter at base, or the tensile and compressive strength of bricks and jointing material. This company claim that the strength of their brickwork enables them to design very economical and efficient chimneys, but one would like to learn a little more about the wind pressure they are capable of resisting.

Improving an Old Chimney.—A chimney not powerful enough for its work may be improved by lengthening, or by the application of a moderate forced draught, such as the Meldrum system of steam jets in a closed ashpit. This system can also be made powerful enough to do the whole work with only a short iron shaft, but iron or steel shafts are very perishable, and brickwork is worth the extra cost, particularly as a tall chimney discharges the foul gases of combustion at a better height for dilution by the atmosphere. The importance of the latter point will be understood from the fact that the boilers described above would discharge about 40,000 cu. ft. of carbonic acid gas per hour into the atmosphere.

UNDERGROUND STREET CONSTRUCTION.

A proposed underground highway for foot traffic, to be built in the upper section of New York, will affect a populated area of half a square mile or more, and will bring about a saving of a quarter to a third of a mile walk to a large number of citizens who are required to use the subway frequently. This tunnel is to overcome the circuitous routes to Dyckman or 181st streets.



Typical Cross Sections—Tunnel Street, New York City.

The tunnel will open off from Broadway at grade a few feet from Fairview Avenue. The general level of the floor will be reached by going down two short flights of steps. The "street" will run 904.40 feet straight away down a 1.09 per cent. grade to a point 35.18 feet west of the subway station and then turn practically at right angles ending in front of the elevator by which the Interboro Company con-

veys its passengers to and from the street, 153 feet above.

The tunnel will be twelve feet wide and twelve feet high in the clear, the sides running up six feet straight to the arched roof, which will have a radius of six feet.

The entire construction will be of concrete reinforced with steel in the walls and roof, and permanently shored with timbers where necessary. With the exception of 173 feet at the street end of the tunnel, the entire excavation will be through solid rock, which fact of course greatly increases the cost of construction.

The contract for the construction of Tunnel Street has been awarded to Roswell D. Williams, 21 Park Row, Manhattan, at an aggregate bid of $72,260. An itemized schedule of the prices follows: 5,900 cu. yds. of rock excavation at $6.75 per yd., 2,300 cu. yds. of earth excavation at $1.20 per yd., 1,200 cu. yds. of refilling at 30 cts. per yd., 2,200 cu. yds. of concrete at $7.78 per yd., 750 cu. yds. of excess concrete at $6 per yd., 200 cu. yds. of dry packing at $2 per yd., 30,000 ft. (B.M.) of timber at $30 per M., 1,000 lin. ft. of galvanized wrought iron pipes at 50 cts. per ft., 800 lin. ft. of 6-in. pipe drain at $1 per ft., 360 sq. ft. of concrete (steps, landing, sidewalk, etc.) at 40 cts. per ft., 10 catch basins at $20 each, 33 sq. yds. of surfacing at 15 cts. per yd., 11,000 lbs. of steel beams and girders at 5 cts. per lb., 5,000 lbs. of steel rods and bars at 4 cts. per lb., 11,000 sq. ft. of floor finish at 10 cts. per ft., electric system (for lighting) complete $1,150.

The construction of the tunnel is expected to have an appreciable influence on the development of that section of Manhattan which it affects.

The difficult and devious approaches to the subway stations have hitherto constituted an indubitable and serious deterrent to the popularity as a residental section of a large area in that neighborhood. With its electric lights, adequate drainage and ventilating provision and equable temperature, the underground street will do much to relieve the discomfort of the transit situation.

PRESERVATION OF POWER TRANSMISSION POLES.*

By W. R. Wheaton.

The increasing cost of power transmission poles in recent years and the high maintenance charges have turned the attention of power companies to some process to increase the life of the poles and to cut down the maintenance charges. The first cost of the poles has nearly doubled in the past six years, and these two factors have been largely responsible for the interest shown by operating power companies in pole preservation.

In March, 1908, the San Joaquin Light & Power Corporation set a line of Western yellow pine (Pinus ponderosa) poles. The line is about 30 miles long and contains approximatel 6000 poles. These poles were cut in the Sierras above Fresno at an elevation of about 4,000 ft., and were thoroughly seasoned before treatment. Some of the poles received a brush treatment with carbolineum and with creosote, and the rest were treated in an open tank with creosote, zinc chloride and crude oil. The butt only was treated. Western yellow pine is very susceptible to a preservative treatment. Some of the butts were thoroughly penetrated with creosote and with zinc chloride, the average penetration (at the ground line) being 3 in. The penetration with crude oil averaged about 1½ in. The crude oil used was a heavy oil of asphaltum base supplied from the Kern River fields. In order to get a comparative life of the wood treated and untreated, stubs of untreated timber were set along the line about a mile apart. The writer inspected this line in June, 1910, at which time it had been set for twenty-seven months. The untreated stubs set along the line were completely rotten. Of the poles brush-treated with carbolineum and creosote the conditions were about the same, a large percentage of each showing signs of decay; 27 per cent. of the poles that had a brush treatment with creosote showed signs of decay, and 29 per cent. of the poles that has treatment with carbolineum showed decay, while 45 per cent. of the poles treated with crude oil were slightly attacked by decay. Of the poles treated with zinc chloride, 28 per cent. showed attack by decay. The poles treated with creosote in the open tank (over 50 per cent. of the entire line were treated in this way) were all perfectly sound and showed absolutely no signs of decay.

In August, 1911, two of the poles in this line which had received a brush coating of creosote fell over, owing to decay at the butt. During August and September, 1911, the line was gone over and all of the poles which had had a brush treatment of creosote or carbolineum were so badly decayed that they were strapped to a creosoted cedar stub.

The above results speak for themselves. The value of the experiment is apparent and is enhanced by the fact that the timber used will entirely decay, without treatment, in a year.

The San Joaquin Light & Power Corporation is now treating Western red cedar poles at the butts only by the open-tank process. There is no necessity for treating the top, since the top is not subject to decay. With this process the outer ring of sap wood on the cedar poles is filled with creosote, and if the timber is thoroughly seasoned before treatment there is little difficulty in accomplishing this. The penetration varies from ½ in. to 1 in. with an absorption of from 7 lb. to 9 lb. per cubic foot. As for the efficiency of the treatment, treated and untreated cedar poles have been set for four years. The creosoted poles are still perfectly sound, while the poles set untreated have decayed through the sap wood and into the heart.

The question has been asked why zinc chloride, copper sulphate or some preservative other than creosote has not been used to cut down the treatment charges. It was found that several poles treated with chloride of zinc were, after the installation of irrigation systems, in the middle of irrigated fields. The zinc was washed out of them, and the poles had to be replaced after a service of two years. The saving in the cost of treatment by the use of a metallic salt would not mean a saving in the end if many such replacements took place. A 50-ft. creosoted pole placed in the line means an investment of about $25. The use of chloride of zinc would cut this cost to about $24.25, and the saving is too small to be considered against the possibility of the loss of the preservative by leeching out after one or two years.

* Abstract of a paper read at the annual meeting of the Wood Preservers' Association, Chicago. Ill., Jan. 16-18, 1912.

SALT IN ONTARIO.

The occurrence of salt in that part of Ontario which lies entirely in the southwestern peninsula bordering Lake Huron, the St. Clair River, Lake St. Clair, and the Detroit River, according to such exploratory boring as has been done, indicates that there are a number of separate relatively small basins. The beds range from mere seams to formations 200 feet or more in thickness. The supply of salt in Ontario is practically inexhaustible. The bulk of the salt manufactured is used in Ontario. The quantity of salt produced in 1910 was 84,071 tons, valued at $414,978, as compared with 77,490 tons, valued at $389,573, in 1909.

The Canadian Engineer

ESTABLISHED 1893.

ISSUED WEEKLY in the interests of the CIVIL, MECHANICAL, STRUCTURAL, ELECTRICAL, MARINE AND MINING ENGINEER, THE SURVEYOR, THE MANUFACTURER, AND THE CONTRACTOR.

Managing Director: JAMES J. SALMOND.
Managing Editor: T. H. HOGG, B.A.Sc.
Advertising Manager: A. E. JENNINGS.

THE C. N. R. IN MONTREAL.

Some very interesting problems are suggested in the undertakings of the C.N.R., which will be commenced in Montreal next spring. The construction of the three-mile tunnel under Mount Royal will, of course, occupy first place among these. It would now appear that shafts from the surface of the ground may be sunk down to the tunnel at different points throughout its length, and that elevators may there be installed for the purpose of making connections for passengers. One of these shafts will probably be located half a mile or so from the north portal of the tunnel to accommodate residents in that vicinity. It is just possible that a shaft may also be sunk near the site of the look-out, so that sightseers may have access to the mountain through the C.N.R. tunnel and elevator.

At the south portal of the tunnel the line will emerge into daylight at the same level as the present Windsor Depot of the C.P.R., and will then reach across to the harbor. The tracks will be elevated all the way. Near the harbor a freight yard will be provided, the yard being elevated. It is figured that this will possess many advantages over the customary freight yard.

It is suggested that the tunnel should be connected with the subway system, which, it is believed, the requirements for rapid transit will necessitate before long, in such a manner that passengers will be enabled to transfer from one system to the other without coming to the surface.

GOOD ROADS.

On Thursday last a deputation, representative of all parts of Canada, waited upon the members of the Dominion Government to bring up the subject of "Good Roads." The delegation, which numbered about four hundred, urged that there should be aid given by the Federal Government for good roads construction. The inception of the Good Roads policy, the Act for which is now before the House, has been long demanded, and it is certain that this representative gathering will have great effect in securing prompt action. While the question of Good Roads is primarily one for the local municipalities, the counties and the provinces to handle, there is no doubt the Dominion Government can do a great deal to aid the movement. In all probability this aid will be in the form of grants to the Provincial Government for the construction of roads. It is outside their jurisdiction, however, to provide for maintenance.

Aside from the question of grants of money for purposes of constructing roads, the Federal Government must take up the question of the establishment of a Bureau of Highways. If there is to be an extensive system developed throughout the country, there must be developed and trained experienced road superintendents to take charge of the work. Definite standards and uniform methods must be laid down if there are to be adequate results for the expenditure in this connection. Therefore, it would seem that the most urgent matter for the Dominion Government to take up, ranking in importance above the question of grants for construction, is the establishment of a Department of Roads along the lines of the Office of Public Roads of the United States. This Department, however, in our opinion, should not form or be associated with the Department of Agriculture. In the United States such is the case, and at the Convention of Road Builders, recently held in Rochester, the suggestion was made that instruction for highway engineers should be given in the agricultural colleges. This is a mistake, as

the logical place for the giving of such instruction is in the Engineering Faculties of our universities. These faculties have the necessary testing laboratories, and by the addition to their teaching staff of trained highway engineers, adequate instruction in the science of road-making can be given. The problems of road construction properly come under the engineer's work, and, therefore, can be better solved by him.

With a strong Department of Roads valuable data with reference to the wear of different types of roads, the compiling of specifications, etc., can be collected and made available for use throughout the Dominion. There is little question that such a Department is urgently required at the present time.

ENGINEERING STANDARDS COMMITTEE.

The question of an Engineering Standards Committee for Canada has been brought up and discussed a number of times, and it is a matter which must be finally settled at an early date if the engineering profession and the manufacturers are to secure the advantages of standardization of the different materials of construction. The seventh report on the work accomplished by the Engineering Standards Committee of Great Britain has recently been published; this is a document which records the progress in connection with standardization. The personnel of the committee and some idea of their work was published in the January 18th issue of *The Canadian Engineer*. It is interesting to note the progress made during the past year. The report states that the recommendations of the committee for sizes and for tests of materials continue to find their way gradually but surely into a very general use. The use of British Standard tramway rails is continued, the British Standard sections rolled during the year ending March, 1911, amounting to nearly 70 per cent. of the total tonnage produced.

The report states that a proposal has been submitted to the committee for the re-designing of the Standard Sections of tramway rails, so that they may have a uniform width of head throughout the series. The reason for this suggestion is that in the country lighter rails than those employed in the towns could then be laid, while still preserving the same width of head. At present the widths of the tires of cars intended for travelling over the heavier and broader sections are rather wide for the lighter and narrower sections. This subject is receiving the careful attention of the sub-committee concerned, but, having regard to the very extensive use of the existing standard sections, no alteration should be made unless it is clearly advantageous, and is backed by some evidence of a general desire for a change. Among other matters which have been dealt with by the committee, and in respect of which specifications or drawings will be issued shortly, are cast-iron pipes for house drainage, water, gas, and sewerage purposes.

Progress is being made with the standardization of vitrified ware pipes, and in this matter full acknowledgment is made of the assistance which is being afforded by the Institution of Municipal and County Engineers. That body has tabulated the data obtained from its members, and a report has been presented to the committee. A meeting was held to discuss the lines upon which standardization should proceed, and the manufacturing members have beeen aked to consult together and carry out tests with a view of formulating proposals which will be considered in conjunction with those received on the engineering side from the Institution of Municipal and County Engineers.

NEW PSYCHROMETRIC FORMULAE FOR USE IN AIR CONDITIONING.

A specialized engineering field has recently developed, technically known as air conditioning, or the artificial regulation of atmospheric moisture, the application of which to many varied industries has been shown to be of great economic importance.

The following information is abstracted from a paper by Willis H. Carrier, in the November Journal of the American Society of Mechanical Engineers:—

In the blast-furnace work it has increased the net profit in the production of pig iron from 50 to 70 cents per ton, and in textile mills it has increased the output from 5 to 15 per cent., at the same time greatly improving its quality and the hygienic conditions surrounding the operatives. The question of humidity is equally important in many other industries, such as lithographing, the manufacture of confectionery, bread, high explosives and photographic films, and the drying and preparing of delicate hygroscopic materials, such as macaroni and tobacco.

It is believed that its proper application in coal mines would prevent explosions to a great extent.

Accepted data used in psychrometric calculations are based largely on empirical formulae which are incorrect and also limited in their range. The author has therefore developed the following rational expressions, based on the established principles and laws governing atmospheric moisture, the latest results obtained by investigators of the properties of steam and water vapor, and data obtained from his own experiments.

Grains of moisture per pound of pure air at saturation =

$$G = 5284Ds\ (t + 459.64) \div (P - e) \quad \ldots\ldots(1)$$

in which

t = Temperature of saturation, deg. F. ($t + 459.64$ = absolute temperature).

Ds = Density of saturated water vapor at temperature t, lb. per cu. ft. = reciprocal of specific volume of steam (as per values in Marks & Davis steam tables).

$P = 29.92$ = assumed standard of barometric pressure, in. of mercury.

e = vapor pressure of saturated water vapor, in. of mercury.

Also,

$$e = e^1 - [(P - e^1)\ (t - t^1)] \div (2800 - 1.3t^1) \quad \ldots\ldots(2)$$

in which

e = vapor pressure at dry-bulb temperature t.

e^1 = vapor pressure at wet-bulb temperature t^1.

This equation should be used where the true wet-bulb temperature is ascertained by using an aspiration psychrometer. When a sling psychrometer is used, an average correction of 1.6 per cent. must be made for radiation error, making formula read:

$$e = e^1 - [(P - e^1)\ (t - t^1)] \div (2755 - 1.28t^1) \quad \ldots\ldots(3)$$

Formulae (2) and (3) will give values of e with an error of less than 0.5 per cent., assuming Swann's value of the mean specific test of the air between t and t^1 to be correct.

Per cent. of relative humidity = $R = e \div e_2$, in which e is taken from (2) and e_2 = vapor pressure corresponding to saturation at the dry-bulb temperature t.

Let W = grains of moisture per cu. ft. at any vapor pressure e, and W_2 = grains per cu. ft. at e_2; then $W = RW_2$; also, $W = W_1\ (460 + t^1) \div (460 + t)$, in which W_1 = grains per cu. ft. corresponding to the dew point at vapor pressure e.

POWER PRODUCTION IN ISOLATED PLANTS AND COSTS.

In a paper presented to the American Institute of Electrical Engineers, Mr. P. R. Moses gives some interesting figures on the cost of making electricity. The following is abstracted from his paper:—

If heating is a negligible matter, as it is in tropical countries and in many manufacturing and industrial establishments, the choice of a prime mover is governed by the balance between investment and efficiency.

The high efficiency modern producer gas engine and the oil engine by their simplicity and reliability offer many advantages over the high pressure steam plant, and where steam is not used for other purposes to an extent proportional to the power requirements, the tendency is rightly, I think, toward this type of plant.

Two producer gas engine plants recently installed have given results fully equal to the guarantees, and a kilowatt-hour can be and is regularly produced at the switchboard under regular operating conditions for about two pounds of No. 1 buckwheat anthracite or pea coal, and this in plants of a few hundred kilowatts capacity.

One of these plants, of 175 kw. capacity, of which the load curve is given, is making current for 1.14 cents per kilowatt hour, including fixed charge on a power house, etc., for a duplicate equipment. These are the owners' figures and include all charges.

The other plant, a 600-kw. plant, divided into three units is using 1.75 pounds of pea coal per kw.-hr. under regular working conditions, including all fuel used for banking.

As the cost of the gas producer plant is no higher than that of a high efficiency steam plant, the relative merits under the conditions outlined hardly need elaboration.

On the other hand, in another plant, belonging to the same company for which the gas engine plant was installed, the steam engine offered the correct solution for at least part of the plant, because the electricity was practically a by-product of the concentration and evaporation of the sugar solution.

In many instances a combined steam engine and producer gas or oil engine plant offers the best solution, the steam plant being installed to such extent that its exhaust may be fully utilized.

With such equipment, with the exhaust gases from the gas engine used to heat reed water from the boilers, an almost ideal operating condition exists for at least part of the year.

I have investigated a number of isolated plants, operated by oil engines, and find particularly in the small plants that they are giving remarkable service. Almost universal testimony is to the absence of trouble and the reliability of the small sets. With the large units the heavy parts and the unfamiliarity of the operators have given some trouble, but in general the results are satisfactory.

The necessity for steam boilers and the space conditions in city buildings usually preclude any type of plant but steam unless the building is planned from the inception for the gas engine or oil egine equipment. As the engineer is frequently not called in until the general plan is adopted and as space beyond a certain amount is often extremely precious, the usual isolated plant in city buildings in the East is a steam plant.

Costs of Making Electricity.—Some kilowatt-hour costs in buildings follow: These costs are derived by deducting from the total operating cost of the building with an electric plant, the cost of operating without an electric plant. This latter cost is either actual or estimated, depending upon whether street service had been used prior to the installation of the private plant or not. In each instance the fact is stated. I do not go into particulars of each plant because there have been many such figures printed. They are, however, as closely correct as I can make them and are taken from the regularly monthly plant reports.

Where the costs are given for different seasons, the variation is due, of course, to the high cost of supplying heat and engineers services, etc., during the winter and the relatively low cost of these services during the summer.

The kilowatt-hour costs do not include fixed charges unless otherwise stated.

My reason for excluding fixed charges is that each case presents a different condition. Money may be worth 25 per cent. to one man and 3 per cent. to another. With the cost of making electricity before him, each man can then decide if this cost is sufficiently less than the central station charge to warrant investment.

Kilowatt-Hour Costs.

Loft building.—100 by 100 ft. (30 by 30 m.) 12 stories and basement.

Month.	Kw.-hr.	Total cost.	Basic cost.	Mfg. cost.	Mfg. cost per kw.-hr.
April	15080	756.81	300	456.81	$0.03
January	18450	936.26	470	466.26	$0.0252
October.	17810	884.76	300	484.76	$0.0328
July	12060	680.26	200	480.26	$0.04

Cost of plant $12,000. Fixed charges per kw.-hr. approximately ¾c.

Loft building.—185 by 200 ft. (56 by 61 m.) 12 stories and two basements.

Month	Kw.-hr.	Tl. cost	Basic cost	Mfg. cost	Mfg. cost per kw.-hr.
April	36930	1830.25	750	1080.25	$0.029
January	41950	1841.82	950	891.82	$0.0212
October	39480	1643.07	750	893.07	$0.0226
July	31800	1543.04	650	893.04	$0.0281

Fixed charges: ½ cent per kw.-hr. Plant cost, $20,000.

Apartment house: (free light); 36 apartments, high class refrigeration; best service.

Month	Kw.-hr.	Tl. cost	Basic cost	Mfg. cost	Mfg. cost per kw.-hr.
April	17450	1359.86	1016.85	343.01	$0.0197
January	21620	1360.84	1052.29	308.55	$0.0142
October	13500	1208.67	900.75	307.92	$0.0228
July	9350	1074.03	709.82	364.21	$0.0389

Apartment house: (Electricity sold to tenants; 87 apartments; high class refrigeration; best service; large quantity public lighting.)

Month	Kw.-hr.	Tl. cost	Basic cost	Mfg. cost	Mfg. cost per kw.-hr.
April					
January.	18154	2224.59	1749.18	475.29	$0.0261
October.	14885	1920.56	1507.34	413.22	$0.0278
July	11254	1731.54	1226.66	504.88	$0.045

These items are all higher than usual because last year the plant was completely overhauled, new plates installed in storage battery, new condenser for refrigerating plant, new hot water tank etc., all of which is charged off during ten months from date of expenditure.

Office building: 100 by 100 ft. (30 by 30 m.) 12 stories; tungsten lighting; four elevators.

Month	Kw.-hr.	Tl. cost	Basic cost	Mfg. cost	Mfg. cost per kw.-hr.

Switchboard	5— 10
Foundations	5— 10
Steamfitting—including auxiliary apparatus—such as feed heater, grease separator, exhaust head, tanks, covering, etc.	20— 30

The figures of installation cost have been published by me before and I use them in estimating and find them to be closely correct for New York City.

I hope that these figures, together with the other data presented will be of use and will also serve as a basis for discussion and presentation of other facts and figures.

WATER SUPPLY OF REGINA.

Some time ago the municipal council engaged the services of Mr. R. O. Wynne-Roberts to report on the domestic water supplies available in and around the city of Regina.

Mr. Wynne-Roberts' report has been submitted to the council and shows that seven million gallons of water are available daily for Regina, providing the waterworks system is materially extended at a cost of $1,106,045.

By 1918 the 7,000,000-gallon daily supply would be insufficient for the demand, if the growth of the city continues at its present rate. By that time Regina will have to look to the Saskatchewan River, or Long Lake for a supply.

The report gives details on all available sources within a radius of fifteen miles of the city, as well as details of the foregoing expenditure which is as follows:—

At Boggy Creek: New pump well, $7,271; manhole, No. 1, $16,406; manhole, No. 1, $6,880; manhole, No. 2, $2,750; pump well to steam pump well and Zimmerman Br., $47,889; laterals, pipe lines, $2,000; two meters, at pump well, $2,000; one meter, at power house, $1,000; sinking wells and pump at Boggy Creek, $2,000; making a total of $88,206. The works outlined, in conjunction with those already in use, are contemplated to give a daily supply of 3,000,000 gallons.

Outlining a comprehensive Eastern Regina water scheme, it is pointed out that it has for its object the connection of several water-sheds into one trunk main, which would be conducive to economy. The works are designed so that they may be carried out in sections, as the council deems necessary.

It is proposed to lay a collection main in the ravine lying east of Rastadt to open out the springs and convey the water in vitrified pipes to main springs draining the water into the collecting mains. At a point where the collecting mains will terminate it is proposed to install a gasoline engine and pump with pump house and residences for men. The water will be collected in a suitable well and pumped

through a steel main about eight and one-half miles in length, along road allowances, and there discharged into a circular reinforced concrete reservoir. Although the supply is dependent to a large extent on wells and underground water-sheds, certain sprinks will play an important factor if this report is adopted and carried out.

The estimates of the cost of the proposed works are placed under four heads, as follows:—

Silver Stream Section.—Pipe lines, $274,740; 400 h.p. engines and 7,000,000-gallon pumps, $20,000; pump well, $20,000; engine house, $2,000; cottages, $4,000; meters, water level recorders, $8,000; contingencies, $32,874; making a total of $361,614.

Slough Creek Section.—Pipe lines, $163,056; meters, $6,000; contingencies, $16,950; making a total of $185,961.

Hicksvale Creek Section.—Pipe lines, $270,400; two 1,000,000-gallon reservoirs, $35,000; meters, $6,000; turbine pumps and station, $6,000; cottage, $2,000; contingencies, $31,940; making a total of $351, 340.

Rastadt Springs Section.—Pipe lines, $179,300; engine, pump and building, $6,000; cottage, $2,000; meter, $1,000; contingencies, $18,830; making a total of $207,130.

It is proposed to deliver the water to the city through a steel main to be laid from Silver Stream along Dewdney Street and connect to the city water mains at a convenient point. It is proposed that the city water pressure should be maintained at about 65 pounds per square inch—that is about 150 feet head, which will be sufficient to provide an ample supply to the highest building in the city. The system would be capable of supplying water under a greater pressure when necessary

It is estimated that the combined scheme and watersheds described will probably yield a total supply of about 7,000,000 gallons per day. It is pointed out that it would be advisable to install self-recording meters on the various sections.

THE ST. JOHN VALLEY RAILROAD.

The contract for the construction of the above mentioned railway, when completed, will be a great impetus to commerce in the Maritime Provinces, particularly New Brunswick. The route, as described in the contract, is, briefly, from a point on the National Continental Railway at or near Grand Falls, via Centerville and Lakeside, to Woodstock, thence by the River St. John to Fredericton and Gagetown, thence crossing the St. John River at or near the Mistake, thence crossing the Kennabacasis River at or near Perry's Point, and thence to the city of St. John, the whole representing 208 miles. It is provided that the divisions from Fredericton to Woodstock and Woodstock to Centerville shall be completed on or before November 1st, 1913, and the whole road is to be completed on or before November 1st, 1915. The Provincial Government guarantees the bonds of the company to the extent of $25,000 per mile.

The road now under contract is one link in a chain of railroad development. Logically connected with the St. John Valley is the proposed line known as the St. John and Quebec Railroad, which it is planned to cross the State of Maine from a point of connection with the Aroostook Valley Road at Washburn to the western boundary of the State, from which point a line is chartered by the Dominion Government to run to the St. Lawrence River, fifty miles.

When these two sections of road are completed, the distance by rail from Quebec to St. John will be 370 miles, and a very important saving will be effected in transportation in these portions of the Dominion. Mr. Ross Thompson is the chief engineer, and Mr. S. B. Wass the assistant chief engineer of the company.

FORESTRY OPERATIONS ON THE PENNSYLVANIA RAILROAD.

An important work of interest to railway officials and others is the conservative management of the Pennsylvania Railroad timbered lands. The logging operations which have been conducted by the company's foresters during the last three years cover a total area of about 1,200 acres and form only one of the means which are being used by this railroad to solve the problem of procuring ties and other timbers. It has been in use for three years, during which time 2,600,000 board feet of lumber and 15,000 ties were procured from woodlands managed by the foresters. The tracts on which they are applying the principles of silviculture include small areas along the right-of-way which have no value to the company except from the timber which is growing on them, and the more extensive areas of land which are the catchment basins for the mountain reservoirs which supply water for locomotive and shop use.

Logging operations as carried on by the foresters have in view the best utilization of the standing timber and the conservation of the supply for future operations. Although the aim is to leave each tract logged in more productive condition than before, each case presents its own peculiar conditions, and must be considered as a separate problem. On many unmanaged timber tracts frequent fires have added to the injury caused by partial cuttings. In extreme cases the result of such fires and cuttings is that there are no young trees which are worth leaving and the mature trees are badly damaged. Under such extreme conditions the area, as a rule, would be cut clean and a complete planting made. The other extreme condition evists when the area has been free from fires and cuttings and the growth is so well graded in age that it is possible to cut out matured trees and still leave sufficient young growth to stock the area. The most prevalent condition, however, lies between these two extremes, and the methods adopted under such conditions are well illustrated by the work done on the Brush Mountain tract near Altoona, Pa., according to the Railway Age Gazette. This tract includes about 700 acres in the drainage basin of the reservoirs which store the water for use in case of fire at the Altoona shops. Forest growth conserves and purifies the ground water supply, and in order properly to care for the timberlands in drainage areas the officers responsible for the water supply were glad to avail themselves of the services of the company's foresters. The tract under management lies in a basin-shaped valley known locally as the "Kettle." The slopes are steep, with a range of about 400 ft. in elevation. The forest on most of the area was second growth in blocks of even age from six to eighty years old, resulting from fires and partial cuttings. There were also some virgin trees which had been left because they were not merchantable. Three types of timber are distinguishable. The bottom land bears hemlock, white pine, black birch, red maple, white ash, cucumber tree, tulip, basswood and black ash. As this low ground is continually moist, fires have never been able to run over it, and on that account the reproduction is good. The slopes, which include most of the area, have white oak, red oak, scarlet oak, black oak, chestnut, beech, black birch, white pine, pitch pine, black gum and pignut hickory. Fires have repeatedly run over these areas, with the result that there is very little ground cover and reproduction is mostly of sprout origin. The ridges are dry and the scattered timber was stunted and of poor quality. The principal species are chestnut oak, black oak and pitch pine. The reproduceion is so poor as to be hardly worth considering. Many trees on the tract had been seriously damaged by fire and wind, and many

were dead or dying, so that much of the lumber was fast decreasing in value.

On account of the mutilated condition of this forest a very heavy improvement cutting was necessary. The intention was to remove everything that could possibly be removed without interfering with the water conserving value of the property or reducing the productive capacity of the land, and ultimately to secure a stand which would produce timber usable by the railway. To these ends there were removed in the cutting all mature, damaged and dead trees of all species; all trees of merchantable size, except where needed for reproduction; and every tree of the following species: gum, scarlet oak, birch, sassafras, ironwood, dogwood and witch hazel. The foresters of the company personally marked all trees for removal. In this marking a short-handled axe is used to blaze the trunk breast high and just below stump height. To identify the mark, a sharp blow is struck in the bare spot with the keystone brand of the head of the

Locust Grove, Planted in 1902.

axe. In the process of marking, many barren spots were found which had been so badly burned that there could be little or no natural reproduction of desirable species. On these areas it was decided to plant three-year-old Scotch pine seedlings where the soil is not too rocky and to sow white pine where there is not sufficient soil for the Scotch pine. A contract was let to an experienced woodsman for all logging on the tract, the contractor agreeing to deliver the manufactured timber on cars at Altoona. This contract also covered taking tanbark and the other by-products, except charcoal, which was covered under a separate contract. The tanbark was taken first, the work beginning early in the spring. Only hemlock and chestnut oaks were usable as tanbark, and the trees which were cut for their bark were allowed to remain where they fell until the beginning of the logging. For getting out the sawed timber, a portable sawmill having a capacity of about 5,000 board feet a day was used by the contractor. The foresters in charge of the work at first designated to the contractor what form of timber should be made from logs of a given species and size, but as the contractor had had considerable experience in this work and was intelligently interested in this conservative logging, the matter was left largely to his judgment with frequent checks by the foresters. The contractor was so well satisfied with the results of the marking that he has since sought to employ the company's foresters to mark trees on his own land. In general, ties were made from white oak and chestnut oak trees of a diameter which would just make one tie, as it was more profitable to saw logs large enough to make two ties into bridge timbers, crossing planks or smaller sticks. The contractor was required to avoid injury to young trees throughout the work by so felling trees as not to strike any trees not intended for removal, by not cutting saplings of desirable species for use in logging operations, and by not locating roads through young growth. All stumps were cut low, the rule being that the stump of a sound tree should not exceed in height half the diameter of the tree at stump height. The surface of the stumps was left smooth and in good condition so that desirable sprouts would be more readily produced. Branch wood and refuse was cut so as to lie close to the ground and thus rot more readily. Since cordwood was not readily saleable in the vicinity, it was necessary to make charcoal from the unmerchantable timber.

Both the contractor for the logging and the one for making the charcoal agreed to exercise every possible care in preventing fires and in fighting them when once started. This is the most important provision that can be made in managing timber land. During dry weather a man was kept patrolling the tract continually, and in case of an alarm of fire the contractor was required to set every man in his force to fighting the fire.

Up to the present time about 1,200,000 board feet of lumber, 5,000 cords of charcoal woods, 90 cords of paper wood, 130 cords of tanbark and 189,000 lath have been made from this tract. Of this amount the following was taken by the Pennsylvania Railroad:

Lumber—		
Oak	110,000	board ft.
Pine	124,000	" "
Hemlock	71,000	" "
Chestnut	3,000	" "
Crossing plank—		
Oak	33,000	" "
Chestnut	6,000	" "
Ties—		
Cross	678	
Switch	70,000	board ft.
Bridge	57,000	" "
Fence posts	2,971	pieces
Charcoal	153,404	bushels.

The products that could not be used by the railway were sold to outside parties. All products taken by the company are charged at market prices, and on this basis the operations on this tract have netted a profit of over $12,000 to date, including in the expenses all supervision and technical administration of the work.

The cost of practising forestry in this manner is calculated by the department at about five cents for each thousand board feet. Since the net profit on the 1,200 acres logged has averaged about $23 per acre (stumpage not charged), and this is typical second growth land which has been considered of little value, it is evident that if the example of conservative logging set by the railway were followed by other land owners in the state the amount and value of forest products, both present and future, would be greatly increased.

The company's purchasing agent always gives the forestry department a chance to fill a requisition for lumber before an attempt is made to buy it elsewhere. If any of the material needed can be supplied from the company's tracts the order for it is placed with the forester. In order to provide seedlings for planting the company conducts a nursery at Morrisville, Pa., where commercial trees are grown and ornamental stock is carried for use on the system. The total area under cultivation is 38½ acres and the annual capacity is about one million trees. Comparing the cost of producing the trees at the nursery with the market price, the net saving to the company for the year 1910 was about $6,000. The planting of trees on unused land has been

carried on since 1902. During the nine years up to and including 1910, there were set out 4,099,524 trees. This planting has been done on tracts of various sizes and under various conditions. Whenever a tract is turned over for forestry purposes a careful examination is made to determine how it can best be used. If it is already wooded the timber is inspected, and if the stand is sufficiently valuable the tract is carefully logged and conservatively managed. If it must be cut clean, or if it is already a clear area, the advisability of planting it is considered. If it is to be planted, the species which will grow best in that soil must also be decided on. The planting may be done either in the spring or fall, preferably in the spring. This work is done by squads of men who are employed locally. They work over the ground in two rows, the men in front cutting the sod and digging holes with mattocks, and the men behind, who carry the seedlings in buckets partly filled with water, planting them in the holes. The trees are set in rows, the location of each tree being determined by the planters by sighting stakes or by following stretched lines. Under favorable circumstances a squad should plant 400 trees per man per day. To grow tall and straight trees desirable for timber is is necessary that the seedlings be planted close together, the approved spacing in most cases being six feet in both directions. After several years this growth may require thinning if the stand is good, although the natural suppression of a considerable number of the seedlings must be expected. Along all such plantations which adjoin the right of way a fire line is kept plowed to guard against the spread of fire from locomotive sparks. Most of the older plantations are of black locust, and it is to be regretted that this species is being attacked by borers with considerable damage to the young trees. The borers attack both good and bad trees, and, although they do not kill the trees, the holes they make cause many of the trees to break and to a marked degree weaken the timber which can be made from the tree. The locust leaf miner is also attacking these plantations, with the result that the growth of the trees is retarded through lack of nourishment, since the leaves cannot perform their functions after they are attacked by the miner. Although the locust grows well in Pennsylvania and makes desirable trees, posts, etc., it does not seem practicable to continue its planting for these purposes until some method can be devised to prevent the damage by these insects.

Various lines of experimental planting are attempted from time to time. As an example of this class of work, two double rows of evergreen trees were planted near Glen Loch, Pa, in 1910, to serve as a snow fence. The wooden snow fences commonly used require considerable maintenance, and it is thought desirable to substitute growing evergreen trees where conditions are favorable. Their use, however, requires a wide space between the track and right of way line. In the planting made, the first row of trees is Scotch pine planted 100 ft. from the track, while the outer row, of Norway spruce, is planted along the property line. To save expense, small trees were used in this planting, but it is thought they will be large enough in a few years to drop the snow behind them successfully.

ELECTRIFICATION OF BRITISH RAILROAD.

The consulting engineers of the London, Brighton & South Coast Railway are preparing plans for the further electrification of the company's suburban services and the extension of the electrification schemes to the main line.

MANUFACTURING BUILDINGS.

The following data appeared in an address by Mr. E. H. Darling, assistant engineer of the Hamilton Bridge Works Company, Hamilton, given before the Engineering Society of the University of Toronto. The remainder of the address was printed in the November 9, 1911, issue of The Canadian Engineer under the title of Preliminary Problems in the Design of Manuafacturing Buildings.

1. Slow burning or mill construction.
2. Fireproof construction.
3. Steel frame construction or mill buildings.

Slow burning or mill construction is simply a special class of timber work. Such a building will have heavy brick walls with the interior columns, beams and floors of massive timbers so disposed as to present the least possible opportunity for the spread of fire. The columns are made of single timbers, usually square, capped with a corbel or short beam which forms a seat for the column of the next floor above, and supports the cross beams which carry the floor. This corbel may be replaced by a steel or cast iron cap which is more reliable when the loads are great. The cross-beams are also heavy single timbers, and on these are laid 2-in. by 4-in. or 2-in. by 6-in. pieces set on edge and spiked together, so as to form a floor 4 in. or 6 in. thick, as the case may be. A hardwood wearing floor 1 in. thick is usually laid on this. Note the absence of all joist and any thin projecting woodwork which might easily catch fire. In case a fire should start, the thick floors would tend to confine it to one story and the heavy beams and columns would burn slowly, thus giving the fire department a chance to put it out before it destroyed the whole building. This construction is only effective, however, when used intelligently, for unless all the many rules for preventing the spread of fire are carefully observed, the result may be disastrous.

The roof of such a building may be constructed like the floor, or, if the span between the rafters is not too great, matched sheeting may be used. This is covered with a felt and gravel roofing material or some one of a score of special roofings which will resist the attack of fire.

The cost of long timber of large cross-section practically limits the length of beams to somewhere between twelve and sixteen feet. This means that in a wide building there will have to be many columns, which take up room and interfere with the arrangement of machinery.

2. Fireproof Construction.—While there might be a difference of opinion as to how far it is expedient to go in making a particular manufacturing building fireproof, it is well understood that, if a building is to stand all the vicissitudes of a conflagration, it must be made entirely of brick, concrete, terra-cotta, and steel, the steel to be well protected from the direct heat of the fire.

It is in office buildings, hotels and tenament houses that fireproofing principles have been most extensively applied, and the manufacturer who requires a building of somewhat similar form will use similar methods of construction, adapting them to his special needs. Reinforced concrete may be used entirely for floors, beams and columns, or steel may be used for the beams and columns to form a framework to carry the floors. In this case the steel must be covered with at least 1½ in. to 2 in. of concrete.

Terra-cotta is being introduced for use in certain classes of manufacturing buildings, but, being more or less brittle and not suitable to withstand vibration and shocks, its use is limited. Its most extensive use is in the form of tile for roofs, where its lightness is an advantage.

3. Steel Frame Buildings.—This class of construction is used for rolling mills, machine shops, foundries, etc., which are usually classified under the head of mill buildings. Its distinctive feature is the steel skeleton which forms a frame to support the roof and side covering. This covering is usually corrugated iron, galvanized and sometimes painted also. When so constructed, the building is entirely metal, even the window sash may be made of steel. The result is that it can stand an immense amount of rough usage and unless filled with inflammable material, is not easily injured by fire, nor is it effected by the elements provided it is regularly painted and properly cared for.

But in a building of this class its function as a protection from the weather is really secondary, its main duty being to sustain cranes, hoists, and other machinery. In fact the structure is a huge machine itself. In its design the same engineering principles are applied which are used in the building of steel bridges. Every possible stress is estimated and provided for. Often the analysis of these stresses is made extremely complicated by special combinations of traveling cranes, bins, machinery and wind pressures, but all must be taken care of if the building is to be rigid and safe.

Each of the above three types of construction has its own special advantages, and they are often combined in various ways to obtain a desired result. The slow-burning construction has the advantage of being cheap in first cost. Until recently it had a further advantage of time in rapid erection, but it is now so difficult to obtain first-class lumber and the cost is such that these advantages are lost. The commercial size and length of timbers obtainable also limits the span of beams and the spacing of the columns, as explained above. However, for factory buildings, such as woollen and cotton mills, etc., where the machinery is small and light, this feature is not necessarily objectionable. But the one which weighs heaviest against it is its inflammability. That means, for one thing, high insurance rates and the ever present danger of fire.

The first natural variation, made in slow burning construction, is the substitution of steel for beams and columns. This permits longer spans for the beams and heavier loads on both beams and columns. Steel columns are often put in the outside walls as well. The steel work is then self-supporting and may be erected complete independently of other trades. As these columns relieve the walls of all beam loads, and also reinforce it, the walls may be made much lighter than would otherwise be permissible. As a fire risk, however, this combination is considered inferior to the slow burning construction. Steel becomes soft at a red heat and is entirely unable to resist stresses. If, when thus heated, a stream of water is directed on it, it warps and twists. While an ordinary fire will not actually destroy the metal, the physical state of the material may be so altered as to be entirely unreliable. Consequently its salvage value is only what it will bring as "scrap."

In buildings of three or four stories, round cast iron columns are sometimes substituted for the rolled steel. If neatly cast, they present a better appearance than the built-up steel column, but unless designed by one accustomed to working with cast iron, and unless they are most rigidly inspected, there is always a very great uncertainty as to their strength. Apart from this unsatisfactory feature, cast iron has the advantage over steel in being better able to resist heat. They will usually cost more than the steel column.

If, in buildings where steel is used, it is protected by about two inches of concrete, practically all the risk of damage from fire is eliminated. This is rarely, if ever, done if the floors are of wood, for if the fireproofing is carried to this extent, it only means one step more to make the building entirely fireproof. Wood floors, however, have this advantage, in addition to being cheaper. It is much easier to cut openings or bore holes in them than it is in concrete, and that is an item worth considering where there is likely to be much of this work to do.

As stated above, buildings which are to be fireproof must be constructed entirely of reinforced concrete, or steel covered with concrete or terra-cotta. Buildings of this type have come through conflagrations and earthquakes with credit. The one thing to remember in using reinforced concrete is that there must be no slighting of the work whatever. To get a good job, it is sometimes a continual fight against ignorance and carelessness, and sometimes dishonesty. A mistake once made is very hard to remedy. A defect may easily escape notice until a catastrophe occurs. Many accidents have already been recorded and there have probably been many more that have never reached the ears of the public. There are large new buildings which stand finished, but vacant, and condemned.

That this blot against reinforced concrete is not fair to this construction, is proved by the fact that many engineers, especially European engineers, get quite satisfactory results although they use much higher unit stresses than the average. The secret is that they take more time for the work, and give it more rigid supervision.

By using a steel frame work for a building, much of the uncertainty as to its safety may be done away with. There is also a saving of head and floor space, as the steel beams and columns are smaller than those of reinforced concrete. In a building of many stories a few inches to each story adds up to quite an item. The columns in the lower stories become so large that, as one writer has put it, the building resembles the Egyptian pyramids—most of the room is on the outside. Nor are engineers agreed as to how concrete sets when poured wet in large masses.

There are other objections to the use of reinforced concrete for certain classes of manufacturer's buildings. Where it is necessary to make frequent changes, alterations and repairs and, in fact, in any structure that is not intended to be permanent for many years, it becomes very costly. When it has outlived its usefulness it is expensive to remove and the materials have little or no value.

Referring to steel frame mill buildings, structural steel has other useful properties in addition to those referred to above. Such a building is not limited to any size, shape or form within reason. Any loads can be taken care of with certainty. The erection of the frame usually goes ahead very rapidly, forming a scaffold for other work. Steel must, however, be frequently painted if exposed to moisture or corrosive gases to prevent rust and corrosion.

REINFORCED CONCRETE.

Mr. G. C. Workman, M.S.E., M.C.I., read an interesting paper recently on "Some Recent Works in Reinforced Concrete," before the Concrete Institute of England.

The object of the paper was to describe a few of the numerous works recently executed in reinforced concrete, and to bring out some of the more interesting features of each particular case, and to show how various difficulties had been overcome. The author said that, owing to modern requirements, there was a growing tendency for the various barnches of engineering to become specialized in order to obain by a continual study of each subject, the maximum amount of economy and efficiency.

It was for that reason that a certain number of engineers had become specialists in the designing of reinforced concrete, each one adopting the particular method of reinforcement which he thought best suited for the purpose.

Personally, he had for the past ten years been identified exclusively with the "Coignet system," which was one of the first rational and scientific methods of reinforcing concrete.

As there were a certain number of different ways of reinforcing concrete, he first of all gave a short description of the methods employed in the various works which he described.

Commencing with the beams, which were usually considered the most important part of a structure, round bars of mild steel were used, the diameter varying between ⅜in. and 1⅝in. The steel frame-works were designed in such a manner as to form independent units which could be easily made on the site and placed on the centering when required. In some cases the tension bars for the lower portion of the beams were all straight with a corresponding parallel bar in the upper compressed portion of the beam; a mechanical bond between the upper and lower bars was provided by means of stirrups made of round mild steel wire varying between 3-16in. and ¼in. diameter. These stirrups had their ends bent over the top bar, and they were fastened by means of annealed wire to the main bars so that their position could not be changed during the process of concreting. The spacing of stirrups was, of course, varied in accordance with the shearing stresses.

Another method of preparing steel frameworks consisted in grouping together seven tension bars of comparatively small diameter; six of these bars were bent upwards at an angle of forty-five degrees and hooked over a longitudinal top bar ½ in. diameter in such a manner as to form a kind of truss. Additional stirrups were also provided, as in the first method described, to counteract any extra shear.

This last arrangement had the advantage of being more economical than the first one because the section of steel in tension was made to decrease gradually towards the points of support where the bending moments were less, the extra steel being used to resist shear or diagonal tension.

In regard to shear he pointed out that in the first method, comprising vertical stirrups and horizontal bars, the vertical shear was taken up by the main bars and the horizontal shear by the vertical stirrups, whereas in the last-mentioned alternative the vertical and horizontal shear, or, in other words, the diagonal tension, was counteracted by the bars bent at an angle of forty-five degrees.

The longitudinal top bar was, of course, necessary for the preparation of each unit. This bar was very useful to suspend the framework in the centering, and as it was situated in the upper portion of the beam it increased the resistance to the compression. The upper ends of the stirrups and shear members was secured by means of hooks to the top bar. That precaution was in accordonce with the new rules of the Joint Committee of the Royal Institute of British Architects, which state that in every case care should be taken to bend or otherwise secure the ends of the rods to prevent them from slipping in the concrete.

The negative bending moments in beams were counteracted by joint bars of sufficient length.

In many of the buildings the steel frames of the pillars were made horizontally and placed in position in the casings when required. The frames were composed of main bars bound together either by 3/16 in. or ¼ in. wire, forming spirals or horizontal ties with a pitch of about 6 in. The object of these ties was not so much for strength as to keep the vertical bars in their proper position during the concreting.

The reinforcement of rectangular floor slabs was provided by simply placing principal bars of about ½ in. to ⅝ in. diameter in the smaller spans and ¼ in. distributing rods at right angles to the others, so as to form a mesh, the bars of which are bent up gradually over the beams in order to resist contraflexure.

As previously mentioned, round bars had been used throughout because they had the advantage of being easily procurable in the open market, and because that section produces the minimum amount of contact between the various bars forming the units. It was obvious that flat surfaces of contact between bars should as much as possible be avoided because rust was likely to develop in such places, and that defect might ultimately become a source of danger. Another reason for round bars being favored was that they offer a better surface of adhesion than any other available section.

BOX LUMBER IN CANADA—1910.

The reported consumption of lumber for boxes and shooks in Canada during 1910 was over one hundred and fifty-eight million feet, valued at two million two hundred and seventy-three thousand dollars. These statistics have been compiled by the Forestry Branch of the Department of the Interior from reports received from one hundred and two box factories, over one-half of which are in Quebec. Seventy million feet of lumber or forty-five per cent. of the total was used in Quebec. Ontario used sixty million feet or thirty-eight per cent. of the total and the remainder was used in the provinces of New Brunswick, British Columbia, Manitoba and Nova Scotia. Pine, the chief species used in Ontario, formed forty-five per cent. of the total box lumber and cost only $13.93 per thousand. This comparatively low price for pine, indicates that with this more than with any other species, mill waste and cull lumber is being used in the manufacture of boxes. Spruce in 1910 was used in every province in which boxes were made, and formed forty-one per cent. of the total. The cost was $13.83 per thousand or twenty-eight cents more than the average mill run price, so that manufacturers using spruce demand the finest quality. The remaining fourteen per cent. of the total was comprised of fourteen other woods, of which hemlock, basswood and balsam were the chief. The most expensive box-wood used was a million and half feet of Douglas fir at $23.00 per thousand in British Columbia. Balsam fir used in the three eastern provinces was the cheapest box-wood reported in 1910 at $8.94 per thousand. It is a wood light in color, tasteless, fairly strong, and its use in the manufacture of boxes should be encouraged.

FORESTRY IN EUROPE.

The productive forest area in 1908 in the Grand Duchy of Hesse in Europe amounted to 182,263 acres. In general the standing timber is composed of sixty-nine per cent. hardwood and thirty-one per cent. coniferous forest. The fir ranks first among the coniferous species. The total yield of lumber in 1908 was 4,575,000 cubic feet. Refuse in so far as it is not suitable for lighter lumber, such as laths or for pulp, is used for firewood. The expenditures for salaries, forest cultivation and road building amounted to approximately $754,000, and the total gross income (from lumber and firewood) was $1,161,931. The capital represented by the forests ($52,665,354) brought interest accordingly at 2.21 per cent. Where intensive forestry of this kind is practised, forest fires are unknown. Sufficient money spent on Canadian forest reserves would greatly reduce the fire danger, maintain an adequate lumber supply for the country and in time become a source of revenue to the government.

Metallurgical Comment

T. R. LOUDON, B.A. Sc.

Correspondence and Discussion Invited

CAST IRON FOUNDRY PRACTICE.

The fight for the adoption of scientific metallurgical management in the cast iron foundry is one that still continues. Large strides have been made toward better conditions. Foundry superintendents are gradually discarding the old unscientific methods of judging the grades of pig iron. Greater reliance is being placed upon chemical analysis. Apathy, on the other hand, still contests the field with a stubbornness that brands it as having its source in ignorance.

Without the aid of chemical analysis, the great accuracy attainable in the making of given grades of steel wherein the carbon content, for instance, may be regulated down to hundredths of one per cent., could not exist. Metallography, a science that may be termed as comparatively new, has been readily and quickly adopted by the steel maker. In fact, history shows that the manufacturer of steel has been quick to reach out and call to his aid any scientific development that could be reasonably called practical. In this respect, the steel maker is far in advance of the cast iron manufacturer. That this is practically due to the fact that cast iron foundries are usually very small in comparison with the huge steel plants, has to be acknowledged; but, nevertheless, there undoubtedly has been and still is to a certain extent, an apathy on the part of the cast iron founder that is difficult to explain.

To take the case of chemical analysis: The wide-awake foundries not only buy their pig iron by analysis, but they also check the product when received. Now and again, though, one finds examples of foundries that are making a commodity, the specifications for which do not call for any particular analysis of iron, perhaps, merely specifying a certain limit of strength. In cases such as these very little attention is paid to the analysis of the pig iron used. To suggest to the foundry manager that it woud pay to check up the analysis even under such circumstances, is, in most cases, superfluous. Yet it would not be difficult to find cases where one-quarter of a day's output could often have been saved had more attention been paid to the iron being used. The fact that **metallurgical supervision pays always** does not seem to be grasped.

There is another factor besides the involved cost to the manufacturer that tends to perpetuate these conditions. If engineers would insist upon being furnished with chemical analyses as well as physical tests for cast iron **in all cases,** a large step forward would be made. In reality, as far as cast iron is concerned, physical tests on bars generally mean very little, as no attention is paid to the rate of the cooling of the bar, a point of extreme importance in determining the ultimate nature of the iron.

As with the making of steel products, so with the manufacture of cast iron; the man who does not recognize the advantages of scientific metallurgical supervision, is being gradually placed at a disadvantage, and the engineer who has to do with cast iron can help materially to bring about such a desired state of affairs by following the course as suggested above.

IMPROVEMENTS AT NOVA SCOTIA STEEL AND COAL COMPANY'S PLANT.

During the year 1911 many important improvements and betterments were effected at the various plants of the Nova Scotia Steel and Coal Company. Processes of manufacture absolutely unique in Canada were adopted, important departments brought to a point where they stand second to none in the world and generally the company maintained its position as the pioneer of the Canadian steel and coal trade.

The most important additions during the year were the installation of a fluid steel compression plant at the open hearth department, Sydney Mines, Cape Breton, and the substitution of hydraulic presses for steam hammers in the forging department at New Glasgow. In taking this step, "Scotia" has again been the first to bring the latest European methods of steel making to Canada and in consequence is prepared to handle a class of profitable business which no other Canadian company will be able to deal with until they adopt similar machinery.

The increased tonnage of finished product arising from recent additions to the rolling mill equipment necessitated the substitution of a 34-inch blooming mill for the old 26-inch mill which was no longer able to furnish the billet tonnage required by the various finishing departments. Many other improvements, but of a somewhat minor nature, designed to effect working economies in the various departments were also installed and the plant generally kept in a very high state of efficiency.

The fluid steel compression plant is designed to improve the quality of the ingots by expelling the gases generated during conversion and pouring, thus eliminating blow holes and other similar flaws. The process, which is fully patented in all the principal countries of the world, will be worked under arrangements with the inventor, M. Harmet, of St. Etienne, France, whose experience and advice are at the disposal of the company. The plant consists of a group of four hydraulic presses capable of dealing with ingots weighing both three and five tons and a mammoth single press capable of compressing ingots of twenty tons and upfards. The machinery is exceedingly massive, several single pieces weighing 80,000 lbs. each and both presses are capable of exerting a pressure of 4,000 tons on the steel while still in the fluid state.

An entirely new ingot car casting and electric stripping plant has also been installed in the open hearth department which it is expected will effect considerable reduction in costs.

During the last two or three years the New Glasgow works have been practically reconstructed and are now perhaps the most efficient in their particular lines of manufacture in the Dominion. The process of modernization was greatly enhanced this year by the erection of the hydraulic forge and new engineering shops. These cover an area of 40,000 sq. feet and are of steel, brick and concrete construction. The hydraulic forge plant contracted for in Europe some nine months ago consists of two presses, the smaller of 600 tons, the larger of 4,000 tons capacity. The latter will be able to deal with ingots weighing up to sixty tons. The presses are operated on the steam hydraulic principle, all the accessories being electrically driven.

To handle the ingots while being heated and forged in this department, two electric cranes, one of 60 tons and the other of 30 tons capacity have been installed. A 30-ton electric crane is installed in the engineering shop and a similar one in the ingot assembly yard.

The completion of this plant will place the Scotia Company abreast of any forge shops in Europe, probably in ad-

vance of any on this continent and will certainly enable it to undertake the heaviest work of this class which the growing demands of the Dominion will call for in a number of years.

Within a short time all the ingots produced at the company's open hearth plant will be rolled on the new 34-inch blooming mill now being installed. This mill, which was built by Lamberton and Company, Catebridge, Scotland, is complete with all the latest electric and hydraulic equipment and will add very materially to the efficiency of the plant. To drive it, a new engine of 4,000 horse power has been erected.

During the year there was completed the installation of an exhaust steam turbine electric plant. This consists of two units of 500 k.w. each operated by exhaust steam from the blooming and bar mill engines. The power thus generated will be used in all the various departments of the plant. Space is provided for a third unit which will be installed as soon as the electrification of the various departments has been completed.

The 800-foot shipping building erected in 1910 was completed during the year and has greatly increased the efficiency of this department. It is equipped with a 50-ton electric travelling crane having a span of 75 feet. The new manufacturing building in which will be housed the spike, rivet, bolt and nut, machinery steel, polished shafting and other smaller finishing departments has been largely equipped. A new department here is a pick-making plant which will produce all kinds of clay and miners' picks. Ample space for further extensions has been left in this department.

All the equipment in the new engineering shop will be motor driven and the entire building is designed along the lines of the greatest possible efficiency and economy. Among the machinery installed here will be one high speed 20 ft. by 6 ft. by 6 ft. Loudon planer; one Smith and Coventry 10-ft. boring mill; one 30-in. and one 21-in. Hulse lathe, two Bertram horizontal boring and drilling machines and one Dallett portable drill and shaft centerer.

THE INFLUENCE OF OXYGEN ON COPPER CONTAINING ARSENIC OR ANTIMONY.

The experiments described in this paper, by Mr. R. H. Greaves, B.Sc., were made to determine the influence of oxygen on certain mechanical and physical properties of copper containing either arsenic or antimony in quantities up to 0.5 per cent. A number of comparative tests in which the metals were cold-rolled down to 0.02 in., or drawn into fine wire, showed that with increasing arsenic, the metal may take up more and more oxygen without suffering deterioration in its capacity for rolling. This quantity of oxygen increases from about 0.05 to 0.2 per cent. as the arsenic increases from 0 to 0.2 per cent., then more slowly to about 0.28 per cent., with 0.05 per cent. arsenic. Above this point the malleability falls off, and with still more oxygen the metal becomes "cold-short." The action of oxygen on copper containing antimony is similar, but in this case a small quantity (about 0.1 per cent.) effects a distinct improvement in the malleability of the metal. The ductility was similarly affected by oxygen. Tensile tests on the case metals showed that increase in oxygen from 0.15 to 0.4 per cent. caused a rapid diminution in elongation; the effect on the maximum stress was not marked. Oxygen has little effect on the hardness (measured by the Shore scleroscope) until a limit is passed, depending on the arsenic or antimony present; above this, the hardness increases rapidly. This limit is at about 0.3 per cent. with 0.4 per cent. arsenic, but is less in presence of antimony. The first addition of arsenic or antimony decreases the hardness of copper containing oxygen. Measurements of electrical resistance show that oxygen diminishes the conductivity of copper containing arsenic, but increases that of copper containing antimony; the quantitive effect of the oxygen has not yet been determined. In an appendix, methods of determining oxygen in copper are discussed. Without denying the accuracy of other standard processes, the author suggests that oxygen may conveniently, and with a high degree of accuracy, be determined by reducing in hydrogen, and weighing the water formed.

*Abstract of a paper read before the Institute of Metals.

STASSANO ELECTRIC STEEL FURNACES.

In connection with the industrial development of the Stassano furnace, the following is of interest:

Since 1909 Major Stassano has been the sole owner of the patents and since then up to the present time he has made the following installations:

For the Societa Elba one 250-kw. Stassano furnace is in operation at Porto Ferrario and an 800-kw. Stassano furnace is to be installed in one of its works in Liguria.

For the Milan steel foundry, Fonderia Milanes d'Acciaio, one 250-kw. and two 100-kw. Stassano furnaces have been installed; for the J. J. Hoehn concern two 250-kw. furnaces, this plant being located at Odessa; for the Electro-Flex Steel Co., Ltd., of Newcastle-on-the-Tyne, three 250-kw. furnaces. A steel works is also being installed in Dunston-on-the-Tyne exclusively with Stassano furnaces.

After several years ago the Italian War Department had adopted the Stassano furnace for their Artillery Construction Shop. The Italian Navy Department will shortly likewise adopt it for the Navy Yards.

UNITED STATES GOVERNMENT REPORT ON THE COST OF STEEL.

The investigation shows that, as would be expected, the large companies have lower costs, partly due to superior efficiency, but also to monopolistic control, especially in ore.

Below are given some average unrevised book costs, which in several cases include transfer costs:

Open hearth billets	$20.87
Universal plates	21.82
Structural shapes	26.52
Merchant bars	28.12
Wire rods	27.21
Black sheets	39.37
Tin and terne plate	71.23

NEWS ITEMS.

The Steel Company of Canada has let the contract for plant extension at Hamilton to the Hamilton Bridge Co.

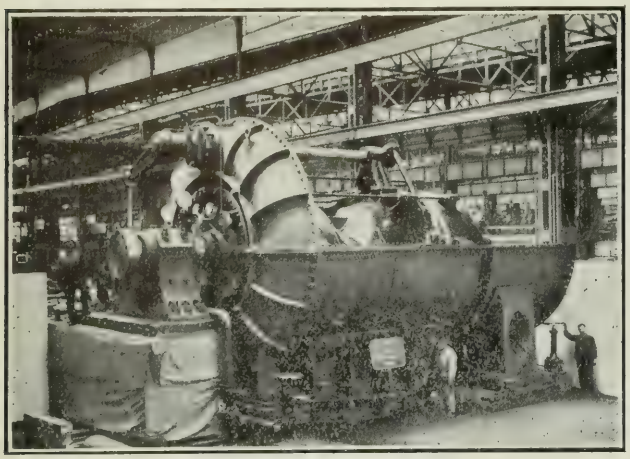
Marsh and Henthorne purpose erecting a new foundry at Belleville, Ont.

NEW ELECTRIC PUMPS.

One or two of the five hundred horse-power electric motors for Toronto's high level pumping station have been in operation for a few hours each day during the past week.

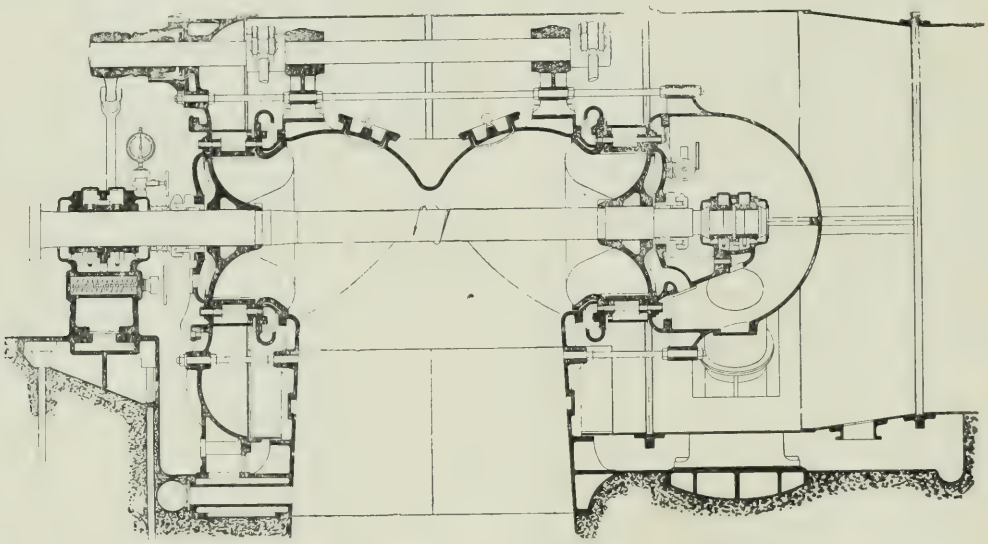
INSTALLATION OF HYDRO-ELECTRIC UNIT.

The first large unit installed by the Western Canada Power Company, Stave Falls, B.C., was started on the 16th of December, last. This unit, which is the largest in Can-



Turbine During Erection.

ada, excepting those at Niagara Falls, was put into service without the slightest trouble developing. After the valve was opened no adjustment was found necessary and the turbine was not again shut down. The present installation comprises two units of 13,000 h.p. each, working under a head of about 110 ft. The hydraulic equipment is supplied by Messrs. Escher, Wyss & Co., of Zurich, Switzerland, Canadian office 408 Lumsden Bldg.. Toronto, and the electrical equipment by the Canadian General Electric Company, of Canada. The accompanying photograph shows the assembling of one of the hydraulic units.



Section Through Turbine.

DEPUTATION FOR GOOD ROADS.

A representative deputation waited upon the Federal Government to urge a comprehensive system of main highways and appropriations for county road construction.

They represented the Good Roads Association of Ontario, the Quebec-Miami International Highway Association, the Toronto and other boards of trade, Ontario Motor League and many municipal and other bodies. The delegation numbered four hundred.

The deputation was introduced by Richard Blain, M.P. for Peel, who laid stress upon the claim that Mr. Borden was the first public man to make good roads a part of his policy. There were two classes who used the roads—the automobilists, who used the middle of the roads, and the farmers and their wives, who were compelled to use the sides of the roads.

Major T. L. Kennedy, president of the Ontario Good Roads Association, pointed out that Ontario possessed 50,000 miles of road, and that there was now no chance of keeping up these roads with the present methods of finance. The Ontario Government had voted a million dollars, but this had all been expended, and if good roads were to be secured Federal assistance was absolutely necessary.

C. J. Foy, of Lanark, emphasized the necessity for Federal aid in the construction and maintenance of good roads. His county (Lanark) had expended $75,000 on 130 miles of road, but it had now come to a point where it could not proceed any further without Federal aid.

Mr. Rankin, M.P.P. for Frontenac, suggested that the Federal Government should pay fifty per cent. of the cost of construction of highways as well as fifty per cent. of the cost of maintenance. There should be township, county, and State highways, and the Federal Government might justly be asked to aid the latter roads.

In reply Rt. Hon. R. L. Borden expressed his pleasure in meeting the delegation and receiving its suggestions. Establishment of good roads, he said, was primarily a matter of provincial jurisdiction. Therefore, it was obvious that the government had a genuine interest in the subject in proposing, as it did, to make grants for the purpose. The condition of roads in Canada was not what should be expected. The civilization of a people was often indicated in its highways.

For Construction.—The premier announced that the supplementary estimates would provide grants to the various provinces for the purpose, but he intimated plainly that the money would be for construction and not for maintenance. In doing the former the government would exceed the B.N.A. Act though doing nothing more than its duty. Details of method of outlay had not yet been determined, but it would be by co-operation with the provinces.

Engineers L. M. Talbot, of Middlesex; H. J. Bowman, Berlin, and E. A. James, of York, were the three engineers accompanying the delegation.

THE CANADIAN FORESTRY ASSOCIATION.

The thirteenth annual convention of the above association has been successfully concluded at Ottawa. The elections resulted in Mr. John Hendry, of Vancouver, being elected president.

Several measures tending toward an increased lumber output were recommended to the Federal Government, among them being the necessity for providing a system of examinations to test the qualifications of appointees and of making appointments permanent during good behavior, and that Federal Government appointments for this purpose should be placed in the hands of the Civil Service Commission. Also, in view of the fact that the expenditure on forest management in Canada is less than one cent per acre of the forest lands, while the average in other countries ranged from two to three cents per acre to $1.90 per acre, that the Federal Government and the Governments of the Provinces should provide large appropriations to assure efficiency of management and increasing profit from the forests of Canada.

It was resolved to impress upon the Government the necessity of maintaining in connection with the forestry branch an experimental laboratory for testing and investigating the physical and mechanical properties of Canadian woods, with a view to extending the possibilities of their use and for other purposes.

The association deprecated the practice of exporting in large quantities of Christmas trees of spruce and balsam, and recommended legislation to prevent that practice.

An executive committee to meet every three months was appointed as follows:—The president, the vice-president, Hon. Sidney Fisher and Messrs. Gordon C. Edwards, R. H. Campbell, G. Y. Chown and Dr. B. E. Fernow.

The committee on forest fire laws reported at very considerable length. This committee is composed of Dr. B. E. Fernow, Dean of the faculty of forestry of the University of Toronto, chairman, and Messrs. Thomas Southworth, ex-Superintendent of Forestry and Colonization for Ontario; W. C. J. Hall, Chief of the Forest Protective Service of Quebec; Ellwood Wilson, forester of the Laurentide Paper Company, Quebec; Dr. Judson F. Clark, forest engineer, British Columbia; Frank Davison, lumberman and member of the Commission of Conservation, Nova Scotia, and G. C. Piche, F. E., chief of the Forest Service, Quebec.

They reviewed the laws of all the provinces, and taking all things into consideration they state that the law of Nova Scotia is probably the most efficient for the conditions there. New Brunswick, Quebec and Ontario have laws which are good in many respects, but they were all primarily designed to protect unorganized territory, and they need to be supplemented by provisions looking to the co-operation of county and township authorities in the organized districts with the officers of the province and the rangers of the lumbermen in the unorganized districts. The laws of the prairie provinces were designed in the first place to stop prairie fires and need to be very considerably supplemented. In British Columbia and the Dominion generally, fire protection is largely a matter of executive administration.

The three main causes of forest fires are railroads, settlers, and persons like sportsmen and prospectors passing through the forests. Regarding railroads, safety there should be sought in improved equipment of locomotives, clearing of the right of way and patrol. In regard to settlers the first suggestion is an educative campaign. Times should be fixed in which settlers must burn the slash from their clearing operations and in each case a permit to burn the same should be secured from the fire warden of the district. Regarding those whose business takes them into the woods, it is suggested that persons like tourists and prospectors passing through the woods should not be allowed to start fires for any purpose without having a permit from the proper officer. Such permits should be for a short time only and renewable upon good conduct. To reduce the danger from lumbering operations the report recommends the burning of slash while the logging operations are going on, or the "downing" of tops and branches so that they may lie close to the ground and rapidly decay.

ENGINEERING NEWS.

Victoria, B.C.—It is anticipated that information relative to the report on the proposed improvements to the outer harbor of Victoria, prepared by Mr. Louis Coste, will shortly be forthcoming.

Victoria, B.C.—That the municipal council select a consulting engineer to confer with the city engineer relative to the necessary work of repair of Smith's Hill reservoir was the suggestion made by Mayor Beckwith.

PERSONAL.

Mr. Willis Chipman, the newly-elected president of the Engineers' Club, of Toronto, is a member of the firm of Chipman and Power, engineers, of Toronto. Mr. Chipman was elected to this position at the annual meeting of this club on February 1st last. Other members elected to office were: 1st vice-president, Mr. T. S. Young; 2nd vice-president, Mr. J. J. Ashworth. 3rd vice-president, Mr. C. H. Heys, Directors: Messrs. Edmund Burke, R. A. Baldwin, W. A. Bucke, E. L. Cousins, W. E. Douglas, H. E. T. Haultain, E. A. James, Jas. McEvoy, A. L. McAllister, G. G. Powell and A. J. Von Nostrand. Secretary-treasurer, Mr. R. B. Wolsey.

Mr. Willis Chipman.

Mr. Ross Thompson has accepted the position of chief engineer of the St. John and Quebec Railway.

Mr. S. B. Wass has been appointed assistant chief engineer of the St. John and Quebec Railway.

Mr. C. W. Powers has been appointed civic engineer of railways, bridges and docks for the city of Toronto.

Mr. Henry Harvie has been appointed chief engineer of the Lake Superior Power Co., Sault Ste. Marie, Ont.

Mr. H. B. Silcox, head of the supply department of the city of Toronto, intends to resign from that position shortly. He will go into business on his own account.

Mr. A. J. Latornel, city engineer of Edmonton, Alta., has reconsidered his resignation notice forwarded to the city officials. He will remain in that position.

Mr. J. D. Whitmore, who has officiated as acting engineer for Moose Jaw since the resignation of Mr. J. M. Wilson some three months ago, has severed his connection with that city. He will return to Regina.

R. O. Wynne-Roberts, M. Inst. C.E., has been appointed by Regina as consulting engineer in connection with that city's additional water supply. Mr. Roberts has also been appointed consulting engineer to report on water supply at Watrous, Sask.

COMING MEETINGS.

THE CLEVELAND ENGINEERING SOCIETY. Special Meeting February 27, 1912, Chamber of Commerce Building, Cleveland, O. "Technical Education (Illustrated)," by Prof. J. F. Barker, Technical High School, Cleveland. Secretary, F. W. Ballard.

THE ENGINEERS' CLUB OF TORONTO, 90-96 King St. West.—Thursday, Feb. 15th. Dinner at 6-30; Lecture at 8 p.m., in Dining Room. After dinner address by Prof. W. R. Lang, Major Canadian Engineers, "Organization, Administration, Duties and Achievements of the Engineering Forces of the Crown," illustrated with models and lantern slides of Bridges constructed by the Royal Engineers in different parts of the Empire. R. B. Wolsey, Secretary.

CANADIAN NATIONAL ASSOCIATION OF BUILDERS.—The Sixth Annual Convention will be held in Toronto, February 20, 1912.

ONTARIO GOOD ROADS ASSOCIATION.—Annual Convention to be held at Toronto, February 26, 27, 28. Secretary, J. E. Farewell, Whitby.

THE ENGINEERS' CLUB OF TORONTO, 90-96 King St. West.—Thursday, Feb. 29th, 8 p.m. Meeting of Toronto Branch of Canadian Society of Civil Engineers. R. B. Wolsey, Secretary.

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE; Secretary, Professor C. H. McLeod.

QUEBEC BRANCH—
Chairman, P. E. Parent; Secretary, S. S. Oliver. Meetings held twice a month at Room 40, City Hall.

TORONTO BRANCH—
96 King Street West, Toronto. Chairman, T. C. Irving; Acting Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the month at Engineers' Club.

MANITOBA BRANCH—
Secretary E. Brydone Jack. Meets every first and third Fridays of each month, October to April, in University of Manitoba, Winnipeg.

VANCOUVER BRANCH—
Chairman, Geo. H. Webster; Secretary, H. K. Dutcher, 319 Pender Street West, Vancouver. Meets in Engineering Department, University.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, S. J. Chapleau, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings,

MUNICIPAL ASSOCIATIONS.

ONTARIO MUNICIPAL ASSOCIATION.—**President, Chas. Hopewell, Mayor, Ottawa; Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.**

UNION OF ALBERTA MUNICIPALITIES.—President, H. H. Gaetz, Red Deer, Alta.; Secretary-Treasurer, John T. Hall, Medicine Hat, Alta.

THE UNION OF CANADIAN MUNICIPALITIES.—President, W. Sanford Evans, Mayor of Winnipeg; Hon. Secretary-Treasurer, W. D. Lighthall, K.C., Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer, J. W. McCready **City Clerk, Fredericton.**

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bec, Lemberg; Secretary, Mr. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

CANADIAN TECHNICAL SOCIETIES.

ALBERTA ASSOCIATION OF ARCHITECTS.—**President, G. M. Lang; Secretary, L. M. Gotch, Calgary, Alta.**

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—**President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.**

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—**President, N. McMurchy; Secretary, Mr. McClung, Regina.**

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—**President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.**

BUILDERS, CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto.

CANADIAN ELECTRICAL ASSOCIATION.—President, N. W. Ryerson, Niagara Falls; Secretary, T. S. Young, Canadian Electrical News, Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, John Hendry, Vancouver. Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; J. Keillor, Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. Frank D. Adams, McGill University, Montreal; Secretary, H Mortimer-Lamb, **Windsor Hotel, Montreal.**

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, D. McDonald, Manager, Montreal Street Railway; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto, President, G. Baldwin; Secretary, C. L. Worth, **409 Union Station. Meets third Tuesday each month except June, July, August.**

DOMINION LAND SURVEYORS.—President, Thos. Fawcett, Niagara Falls; Secretary-Treasurer, A. W. Ashton, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, W. B. McPherson; Corresponding Secretary, A. McQueen.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President, Killaly Gamble; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian Members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain, and W. H. Miller, and Messrs. W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary, R. C. Harris, City Hall, Toronto.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C.B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, W. H. Pugsley, Richmond Hill, Ont.; Secretary, J. E. Farewell, Whitby.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, J. Whitson; Secretary, Killaly Gamble, 703 Temple Building, Toronto.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary J. E. Ganier, No. 5. Beaver Hall Square, Montreal.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, F. S. Baker, F.R.I.B.A., Toronto, Ont.; Hon. Secretary, Alcide Chausse, No. 5 Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Dr. A. McGill, Ottawa, President; Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, J. P. McRae; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Wm. Pierce, Calgary; Secretary-Treasurer, John T. Hall, Brandon, Man.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. Rosevear, 115 Phœnix Block, Winnipeg, Man. Second Monday, except June, July and August, at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc.
Printed forms for the purpose will be furnished upon application.

TENDERS PENDING

TENDERS.

Calgary, Alta.—Plans for the proposed theatre on Eighth avenue, and an application for a permit for the building have been filed at the office of the city building inspector. The cost of the structure is estimated at $30,000.

Calgary, Alta.—Ex.-Ald. J. S. Mackie is contemplating the erection of a $250,000 business block, corner of 8th Ave. and Second Street West.

Calgary, Alta.—Tenders for electric machinery consisting of: One 2,500 K.W. turbo generator; one 1,000 K.W. synchronous motor generator; one 50 K.W. motor driven exciter; one 25 K.W. motor driven exciter. All delivered and erected in Calgary, will be received until March 15th, 1912. J. M. Miller, City Clerk.

Edmonton, Alta.—The school board contemplate calling for tenders for the erection of a $112,000 school building.

Hamilton, Ont.—Tenders will be received until February 28th, 1912, for the supply and delivery of 2,200 lineal feet of 48-inch steel intake pipe with expansion joints, intake and flanged specials, sluice valves, bolts and gaskets. S. H. Kent, City Clerk, City Hall. (See advt. elsewhere in the Can. Eng.)

Hamilton, Ont.—Tenders will be received by the chairman of the Board of Control, City Hall, until February 19th, 1912, for supplying the corporation of the city of Hamilton with the following supplies: Lime, jute packing and reinforced concrete pipe. Specifications at the office of the City Engineer of Hamilton, where forms of tender can be obtained. S. H. Kent, City Clerk.

Hamilton, Ont.—Tenders will be received until February 28th, 1912, for the supply and delivery of 2,200 lineal feet of 48-inch steel intake pipe with expansion joints, intake and flanged specials, sluice valves, bolts and gaskets. Plans and specifications can be obtained from A. F. Macallum, City Engineer, City Hall, Hamilton. S. H. Kent, City Clerk. (See advt. elsewhere in Can. Eng.)

New Westminster, B.C.—Tenders for the erection and completion of two concrete dams, excavation of river channel, in the Nicomeki and Serpentine Rivers in the Municipality of Surrey, New Westminster district, will be received until noon, March 10th, 1912. Drawings, specifications, etc., may be obtained at office of Harvey C. Brice, C.E., Room 3, Westminster Trust Block, New Westminster, B.C.

Ottawa, Ont.—Tenders for structural modifications to Fishery Protection Vessel "Canada," will be received until noon, February 15th, 1912, by G. J. Desbarats, Deputy Minister of Naval Service, Dept. of Naval Service, Ottawa. Full particulars obtained on application to Commander in Charge, H.M.C. Dockyard, Halifax, N.S.

Ottawa, Ont.—Tenders will be received until February 19th, 1912, for interior fittings, Post Office and Customs, Grand Falls, N.B. Plans, etc., at office of Mr. F. L. Dixon, Clerk of Works, Grand Falls; Mr. D. H. Waterbury, St. John, Clerk of Works, and Dept. of Public Works, Ottawa.

Ottawa, Ont.—Tenders are invited for the construction of a Quarantine Station at White Rock, B.C., to be received until March 15th, 1912; specifications, etc., obtained from S. Ranson, V.S., Post Office Building, Vancouver, or S. F. Tolmie, V.S., Victoria, B.C. A. L. Jarvis, Asst. Dep. Min. and Secr. of Agriculture, Ottawa.

Ottawa, Ont.—Tenders will be received unil February 28, 1912, for the reconstruction of approach to the Government Wharf at Sault Ste. Marie, Ont., plans, etc., of which can be seen at the offices of J. G. Sing, Esq., district engineer, Confederation Life Building, Toronto. H. J. Lamb, Esq., district engineer, Windsor, Ont., on application to the Postmaster at Sault Ste. Marie, and the offices of R. C. Desrochers, Secr. Dept. of Public Works, Ottawa.

Ottawa, Ont.—Tenders will be received until noon, February 22nd, 1912, for the installation of new fittings in the Drill Hall at Windsor, Ont. Specinfications, etc., at the offices of the Officer Commanding the 21st Regiment, Windsor; the Officer Commanding 1st Division, London, Ont.; and the Director of Engineer Services, Headquarters, Ottawa. Eugene Fiset, Deputy-Minister, Department of Militia and Defence, Ottawa.

Saskatoon, Sask.—Tenders will be received by the City Commissioners until February 22nd, 1912, for furnishing meters, transformers, wire, globes, and other electrical sup-

plies required by the city during the year 1912. (See advt. elsewhere in Can. Eng.)

Saskatoon, Sask.—Tenders will be received by the City Commissioners until March 8th, 1912, for electrical equipment. (See advt. elsewhere in Can. Eng.)

Saskatoon, Sask.—Tenders will be received by the City Commissioners until March 1st, 1912, for furnishing sewer pipe and junctions, cast-iron pipe and specials, etc. (See advt. elsewhere in Can. Eng. for full details.)

Swan River, Man.—Tenders will be received until February 29, 1912, for the erection and completion of a six-room brick school, for all trades except excavating, concrete and plumbing. Drawing and specifications may be seen at the offices of C. A. Lewis, secretary-treasurer, Swan River, Man.; T. C. Silverthorne, superintendent, Bowsman River, Man., and E. D. Tuttle, architect, 701 McArthur Building, Winnipeg.

Toronto, Ont.—It was decided at a meeting of the Harbor Board to ask at once for tenders for the rental of the city docks, which were recently turned oved to the board by the city. Mr. E. L. Cousins, Engineer to the Board.

Toronto, Ont.—The chairman of the board of control will receive tenders until March 7th, 1912, for the grading and construction of the concrete abutments and wing walls for Coxwell Avenue Subway. G. R. Geary (Mayor), chairman, Board of Control, City Hall, Toronto. (See advertisement in Canadian Engineer).

Toronto, Ont.—Tenders will be received by the board of control up to noon, February 27th, 1912, for the annual supply of asphalt for the year ending December 31st, 1912. G. R. Geary (Mayor), chairman, Board of Control, City Hall, Toronto. (See advertisement in Canadian Engineer.)

Toronto, Ont.—Wm. Panton, County Clerk, Milton, Ont., will receive tenders up to noon, March 4th, 1912, for completing the construction of a reinforced concrete arch of 135 foot span and 340 feet of concrete viaduct approach on the Middle Road between the town of Oakville and the Township of Trafalgar. Frank Barber, Consulting Engineer, Toronto. (See Advertisement in The Canadian Engineer.)

Victoria, B.C.—Tenders will be received until February 16th, 1912, for furnishing and fitting in place steel shelving, etc., required for the vaults of the government offices at New Westminster. Plans, etc., at the offices of the government agent, New Westminster; the Provincial Timber Inspector, Court House, Vancouver; and J. E. Griffith, Public Works Engineer, Dept. of Public Works, Victoria.

Winnipeg, Man.—Tenders will be received until February 20th, 1912, for the supply and delivery f.o.b. Winnipeg, of the following crushing plant: One No. 3 gyratory crusher without back gear driving attachment; to be fitted with chilled iron head and concaves. One No. 5 stone elevator complete with buckets, length 60-ft. One No. 5 revolving screen complete, length 16-ft., in 3 sections, and dust jacket screen. Sections to be made of ¼-in. plate and perforated as follows: 1st section, ¾-in.; 2nd section, 1¼-in.; 3rd section, 2-in.; dust jacket, ⅜-in. M. Peterson, Secretary, Board of Control Office, Winnipeg.

Winnipeg, Man.—Tenders will be received until March 1st, 1912, for the supply and delivery f.o.b. Winnipeg, of the following equipment: 1 44-ton or 45-ton steam shovel equipped with a dipper of at least 1¼-yard capacity, with a clear lift from rail to bottom of dipper door, when open, of not less than 16 feet; 1 locomotive of regular standard gauge to have a hauling capacity of at least 350 tons on a 1 per cent. grade and equipped both front and back with attachment for coupling to standard 80,000-lb. railway cars. Full specifications and drawings must accompany each proposal. M. Peterson, Secretary Board of Control Office, Winnipeg.

Winnipeg, Man.—Tenders will be received by the Chairman, Board of Control, until February 13th, 1912, for the supply and delivery f.o.b. Winnipeg, of one only 24-inch disk rock crusher complete. M. Peterson, Secretary, Board of Control Office, Winnipeg.

Winnipeg, Man.—Tenders will be received by the chairman, board of control, until March 25th, 1912, for the manufacture and delivery f.o.b. Winnipeg, of impregnated paper lead covered cables, to be used in connection with the city's fire and police telegraph system. Full particulars at the office of the city electrician, City Hall, Winnipeg. M. Peterson, Secretary, Board of Control Office, Winnipeg.

Winnipeg, Man.—Tenders will be received until February 22nd, 1912, for supply of three 50-k.w. transformers, motor, and accessories for installation at Well No. 4. Specifications, etc., at office of city engineer, 223 James Avenue. Mr. Petersen, secretary, Board of Control Office, Winnipeg.

Winnipeg, Man.—Tenders will be received by the chairman, board of control, until March 1st, 1912, for the supply and delivery f.o.b. Winnipeg, of a quantity of C. L. water pipe, gate valves, and hydrants for extension of the domestic waterworks system. Specifications and forms of tender may be obtained at the office of the city engineer, 223 James Avenue. Mr. Petersen, secretary, Board of Control Office, Winnipeg.

Victoria, B.C.—Mr. W. Ridgway Wilson, architect, will receive tenders until March 5, 1912, for the construction of St. John's new church edifice. Material used to be brick and terra cotta.

CONTRACTS AWARDED.

New Westminster, B.C.—Messrs. J. Coughlan & Sons have received the contract of raising the high tension wires of the British Columbia Electric Railway Company on the Government bridge across the Fraser River. Contract will involve an expenditure of about $10,000.

St. John, N.B.—The contract for the development of the Grand Trunk Pacific Terminals in Courtenay Bay, St. John, has been awarded by the Government to Norton Griffiths, the English contractor. The contract involves an expenditure of $7,500,000.

Winnipeg, Man.—Messrs. McMillan Bros., railroad contractors, have secured from J. D. McArthur a sub-contract for 185 miles of the Hudson Bay Railway, commencing at Le Pas and extending eastward to a point west of Split Lake.

Vancouver, B.C.—Tenders dealing with the Waterworks Committee in regard to supplies for the Seymour Creek work, have been awarded as follows: The lead piping tender was awarded to Messrs. Robertson, Godson & Company for $3,920. That for the galvanized iron pipe was given to Messrs. Crane & Company at the price of $3,472.50. The contract for the pig lead was secured by Messrs. Evans, Coleman & Evans at $94.08 a ton. The successful tender for the brass goods was that of Messrs. Simson, Balkwill & Company at the sum of $1,054.

Victoria, B.C.—Mr. Harrison, Victoria, has a contract for the erection of a modern two-story factory on Garbally road. Latest kind of electrical machinery to be installed. Owners, Messrs. Hallwards, Limited, furniture manufacturers. W. D. H. Rockfort, architect.

Victoria, B.C.—The contract for the erection of a one-story brick structure for a manual training centre at the North Ward school, was awarded to Messrs. Luney Bros., at a cost of $3,230.

RAILWAYS—STEAM AND ELECTRIC.

The Board of Railway Commissioners for Canada will hold a sittings at the Court Houses at Calgary, Alta., Thursday, March 14th, 1912; Edmonton, Alta., Monday, March 18th 1912; Regina, Sask., Friday, March 22nd, 1912, and at the City Hall, Winnipeg, Man., Monday, March 25th, 1912. At these sittings the board will consider the matter of freight rates in western Canada.

Calgary, Alta.—Surveyors are at work preparing the route for the Calgary Street Railway's extension to the Canadian Pacific Railway Company's shops site, east of the Bow River, and work will be started in the near future.

Fredericton, N.B.—A very attractive station for the I.C.R. is almost completed at this point. Messrs. M. Ryan & Son are the contractors. Considerable concrete paving will be necessary in the spring.

Galt, Ont.—The franchise of the Galt, Preston and Hespeler Railway has been renewed for ten years.

Kingston, Ont.—A contract for 25 locomotives has been placed by the Grand Trunk Pacific Railway with the Canadian Locomotive Company, Kingston, Ont., for delivery May, 1912. These are of simple consolidation type, with Schmidt superheaters, having cylinders 25 inches in diameter by 30 inches stroke, 63-inch driving wheels, and a boiler pressure of 180 pounds.

Moose Jaw, Sask.—The Canadian Northern Railway have closed an agreement with the city council for the entrance into the city, and for the station site. The new station will be at the east end of the city, facing and immediately east of the Crescent Park and baseball ground.

For medium traffic and residential streets.

$ Dolarway Pavement

For permanent state highways, park roads, boulevards, etc.

IT IS PERMANENT BECAUSE IT IS CONCRETE.

What is Dolarway Pavement?

FIVE to six inches of Portland Cement Concrete provided with the necessary expansion joints. The surface is then treated with our adhesive Dolarway Bitumen and with coarse sand or fine gravel or screenings. This seals the concrete, prevents cracking and chipping, and produces a wearing surface which is clean, noiseless, resilient and similar in appearance to other forms of bituminous pavement.

It does not bleed in hot weather, neither does it become brittle or peal in the cold. It is a well-known fact that moisture causes concrete to expand and contract 5 times as much as a change in temperature. Our seal coat keeps out this moisture, thereby preventing the cracking and chipping which would otherwise occur.

What Does It Cost?

You can figure out what the concrete will cost per square yard in your vicinity. Add to this from 25 cents to 35 cents per square yard which represents the cost of the bitumen, sand and labor, and the small royalty charged by our Company.

Great Economy Possible.

Sealing the surface of the concrete by our method makes it possible, for the first time, to construct a pavement or highway having a concrete base and a noiseless bituminated wearing surface at from 50 cents to $1.00 per square yard less than the cost of any other permanent pavement.

Low Cost of Maintenance

The Dolarway Pavement can be resurfaced when necessary at a price of from ten to twenty cents per square yard, thus making it as good as new and prolonging its life indefinitely.

Medium Traffic and Residential Streets.

Permanent, noiseless and dustless. Not affected by motor traffic. Ideal for the smaller cities, as no expensive machinery is required.

For Good Roads.

Wherever there is gravel or stone (hard or soft), you can build Dolarway Pavement cheaper than any other permanent roadway.

Dolarway Succeeds Macadam.

State, County and City officials now prefer to lay Dolarway rather than macadam. This is due to the fact that Dolarway costs only a few cents more per square yard and the cost of maintenance is reduced to a minimum.

Notice to Contractors.

Correspondence solicited from contractors to represent Dolarway Pavement for unallotted territory. Write or call at once for pamphlets and circular telling what Engineers, Contractors and others think of Dolarway.

DOLARWAY PAVING COMPANY

95 Liberty Street,
NEW YORK CITY.

510 Title and Trust Building,
CHICAGO.

One of the methods of applying and spreading Dolarway Bitumen on Concrete Base.

Finished Dolarway Pavement.

North Bay, Ont.—Town Solicitor McNamara is taking necessary steps to apply for a street car charter for the town, to connect with Callander, Trout Mills and Sturgeon Falls.

Northern Ontario.—J. L. Englehart, chairman of the Commission, T. & N. O. Railway, stated that tenders for the construction of the Elk Lake line would be called in the spring.

Ottawa, Ont.—The matter of requiring all electric railway companies in Canada to equip their cars with automatic fenders will be discussed by the Railway Board on March 5 next.

West Toronto, Ont.—It is the intention of the Grand Trunk Railway to double-track its main line from West Toronto to Weston, Ont.

Winnipeg, Man.—The Canadian Northern Railway contemplate building new yards at this point.

Victoria, B.C.—The Canadian Mineral Rubber Company have a large crew at work laying concrete between the double tracks on Burnside road for the Saanich extension of the B. C. Electric Railway Company.

LIGHT, HEAT AND POWER.

Calgary, Alta.—W. R. Martin, of Medicine Hat, one of the promoters of the Canada Western Gas, Heat, Light and Power Company, is reported to have stated that the construction of the pipe line from Bow Island to Calgary will be commenced from the east at an early date.

Calgary, Alta.—Another flow of natural gas has been struck at Bow Island, which will be piped across 181 miles of country to this city.

Duncan, B.C.—A company to supply Duncan with electric light and power is being formed. The promoters expect to have the town lighted by electricity before next autumn.

Guelph, Ont.—A report states that the power consumption in Guelph for January last amounted to $2,300.

Halifax, N.S.—The street railway receipts for the week ending February 7th, 1912, were $3,979.44, an increase of $66.16 over the same period last year.

London, Ont.—Mr. C. B. King, manager of the London Street Railway Company, has been instructed by the directors to secure tenders on a new steam power plant.

Nelson, B.C.—The flat rate system of supplying electric light to citizens was severely criticized by H. P. Thomas, the new superintendent of the city's power and light system. He recommended to the council that the flat rate system be abolished and meters installed in all houses.

Orillia, Ont.—The town of Orillia during this session of the legislature will seek authority to issue debentures for $80,000 to construct a connecting pole line to the Simcoe Power Company's plant at the Big Chute on the Severn River.

Ottawa, Ont.—Hon. Adam Beck is reported to have stated that the provincial government will develop power at Chats Falls on the Ottawa River.

Prince Albert, Sask.—The committee in charge of the municipal power plant recommended that a supply of motors be purchased for renting purposes. F. A. Creighton, City Engineer.

Province of Saskatchewan.—A bill is at present before the provincial government to develop the deposits of lignite, known to exist throughout the province, for power purposes.

Saskatoon, Sask.—The superintendent of the civic power plant, Mr. H. G. Sangster, has been notified that the council approve of the calling of tenders for the following plant: Five hundred housepower water tube boilers with automatic stokers, economizers and independent draught appurtenances; a 2,000 k.w. high pressure steam turbine with generator, condensers, air pump, exciters, and all the necessary equipment for a complete plant. The machinery, which will be placed in the power house will cost $175,000. It will be ten months or a year before the installation is completed.

Winnipeg, Man.—Work on the underground distribution system is to be resumed at once so that the underground district connections may be ready as soon as possible after current is available from the King Street sub-station.

Verdun, P.Q.—The municipal council are considering plans for the extension of the electric light system. Mr. H. Hadley, jr., engineer.

GARBAGE, SEWAGE AND WATER.

Niagara Falls, Ont.—The waterworks board are about to consider certain plans being prepared to improve the intake and waterworks plant. One of the ideas is to introduce a tube below the flow of water at the intake to increase the volume. Other radical changes in the wheelpit and the underground flume will be suggested in the plans which are expected from Mr. Kennedy, Montreal, in a short time. Mr. R. P. Slater, water commissioner, is interested in this work.

Port Stanley, Ont.—This municipality will vote on a waterworks by-law in the near future. Mr. Bell, city engineer of St. Thomas, Ont., is interested in the matter. There are twenty fire hydrants and a large standpipe in the plans now prepared.

Regina, Sask.—Mr. R. O. Wynne-Roberts, who has prepared a report on the new water supply of this city, states that the construction of the first section will entail 6 miles of earthenware pipe from 6 to 18-inches diameter, 5 million gallon reservoir, 3 million gallon water softening plant, meters, etc. The second section will consist of 8 miles of 27-inch steel mains, 8 miles of earthenware pipe from 8 to 40-inches, pumping plant, water softening plant, buildings and small reservoir.

Toronto, Ont. — A report, with estimated costs, on a scheme to supply Toronto with water from Scarboro Heights will be presented to the council at an early date. Mr. I. Randolph, Chicago, is chairman of the board preparing the report.

Verdun, P.Q.—The municipal council are considering plans for the extension of the municipal water system and the filtration plant. Mr. H. Hadley, jr., engineer.

Victoria, B.C.—Mr. William W. Northcote, municipal purchasing agent, is contemplating the purchase of one or more motor trucks to be used in the collecting of house garbage. He is also making inquiries relative to the purchase of twelve garbage waggons.

BUILDINGS AND INDUSTRIAL WORKS.

Edmonton, Alta.—Messrs. Revillon Bros., Ltd., of this city, will erect a six-story warehouse on the Fourth Street spur; the building to be 150 by 150 feet.

Galt, Ont.—The community is seeking authority to overcome certain legal difficulties in connection with the eerction of a municipal abattoir. Mr. McArthur is secretary to the board of health.

Fort William, Ont.—A report states that the Grand Trunk Pacific Railway will erect a thirty million bushel grain elevator at Fort William.

Galt, Ont.—Messrs. Goldie & McCulloch will spend $80,000 on improvements to their buildings and machinery. The Y.M.C.A. will erect a $70,000 structure.

Montreal, P.Q.—A report states that the Dominion Steel Corporation will erect a large warehouse and make Montreal a distributing point for their manufactured goods, such as nails, rods, and all the wire goods which are soon to be turned out by the plant that is now being constructed at Sydney, C.B., Nova Scotia, for this purpose.

Montreal, P.Q.—Mr. Arthur Beauchesne is taking charge of the publicity work in connection with the erection of a monument to Cartier. The cost of the monument will be $10,000.

Moose Jaw, Sask.—An agreement has been reached whereby the Robin Hood Mills of the Saskatchewan Flour Mills Company, will be rebuilt at Moose Jaw. According to agreement the mill must be of concrete construction and the buildings will include a 3,000-barrel flour mill and a quarter million bushel elevator. A 600-barrel oatmeal mill is also on the programme.

Moose Jaw, Sask.—The Rumley Company, manufacturers of threshing machinery, have decided to locate in Moose Jaw. Mr. William Crosbie has been appointed manager of the Moose Jaw branch.

Nanaimo, B.C.—This municipality contemplates spending $50,000 on new school buildings during 1912.

Niagara River, Ont.—The Sanitary Packing Company will erect a large dock half way between Queenston and Niagara-on-the-Lake. The head office of this company is in Toronto, Ont.

The "ENGBERG" VALVE

A VALUABLE ADJUNCT

No waterworks system, having a standpipe or reservoir, can afford to be without this valve, a most valuable adjunct, increasing the effectiveness when fire pressure is desired and permitting a reduction in the cost of maintaining ordinary domestic pressure.

We are sole agents for Canada.

Read what a Fire Chief says—

"Your electric shut-off valve has been a great assistance to us in putting out fires, as it enables the engineer at the pumping station to increase the water pressure in an instant, whereas it took from twenty to thirty minutes to change before the same was put in; a man having to go to the stand pipe and close the valve and also telephone to the engineer notifying him of the same. Now it is all done at the pumping station, and by the time we are able to make connections we have direct pressure. Any chief knows what it means to try and fight fire without sufficient water pressure."

Full Particulars and Estimates Furnished.

Orillia, Ont.—The sum of $60,000 has been placed in the supplementary estimates for the building of an armory, and it is probable that the early summer will see the work of erection well under way.

Ottawa, Ont.—Mr. G. F. Hodgins, of Shawville, P.Q., is president of a new shale brick industry, building operations on which have been started at Russell. It will employ about 100 men and will have a capacity of 100 tons per day.

Ottawa, Ont.—Ald. Lapointe secured the approval of the city council for an initial expenditure of $20,000 on public lavatories this year. A committee will be formed.

Ottawa, Ont.—The civic building programme for 1912 includes the erection of a $45,000 smallpox hospital, $12,500 tubercular hospital, $30,000 fire station and equipment, $20,000 public lavatories. The estimates also include an item of $10,000 for an incinerator site. John Henderson, town clerk.

Ottawa, Ont.—A new telephone exchange for the Glebe section of the city, in addition to the second exchange to be opened shortly in Lower Town, is planned for the near future by the Bell Telephone Company.

Point Grey, B.C.—The Board of Education have applied to the municipal council for $114,200, to be used for the erection of three new school buildings. Mr. M. C. Gordon, secretary of the board of school trustees.

Port Arthur, Ont.—The Canadian Northern Railway will erect a $40,000 dock at this point.

Port Mann, B.C.—The International Milling Company, Minnesota, Iowa, U. S. A., contemplate the erection of a 5,000 barrel flour mill at this point. Mr. F. A. Bean, Moose Jaw, is interested.

Saskatoon, Sask.—The St. James' Anglican Church congregation contemplate spending $10,000 on a new church building. Mr. J. Eadon-Reaney is vestry clerk.

St. Catharines, Ont.—The Sterling Bank of Canada and the Traders Bank of Canada contemplate the erection of bank buildings in this city.

St. Thomas, Ont.—Secretary W. H. Tallman of the board of education states that the plans prepared by Architect John T. Findlay for the proposed extension to the collegiate, had been approved. Work is to be commenced as soon as the weather will permit.

Thorold, Ont.—A new paper plant for this town will employ between 150 and 200 men. The plant will be erected on the frontage facing Grand Trunk Railway tracks.

Toronto, Ont.—The I.O.O.F. Hall Association of Toronto, Limited, decided to build a new $100,000 hall on their property at 229 College Street. The new building will be 130 feet long by 65 feet wide and will be fireproof throughout. It will be five stories high, and will have a large auditorium.

Welland, Ont.—The Canadian Steel Foundries are considering the erection of a $150,000 plant in Welland. B. J. McCormick, Welland, has been looking after a suitable site, etc.

Welland, Ont.—Mr. Wellington Downing, of Erie, Pa., is interested in a project to erect a large hotel in this town during the coming year. The cost is estimated at $150,000.

Winnipeg, Man.—The board of control has ordered the completion of plumbing work at the King Street sub-station, at an estimated cost of $900. Mr. Glassco, power manager.

Victoria, B.C.—It is stated that certain improvements to the outer harbor, now pending, will necessitate the British Columbia Soap Co., and the British America Paint Co., building new plants.

Victoria, B.C.—Mr. M. Warren, architect, has completed plans for a new building to be erected for the Canada Mosaic Tile Company. The structure is to cost $25,000. Mr. Warren will call for tenders for its construction shortly.

Vancouver, B.C.—Plans for the extension of the Great Northern Railway Company's docks at this point are being considered. These plans call for an additional 200 feet of concrete work. The head office of this company is in St. Paul, Minn., U.S.A.

Vancouver, B.C.—It is expected that two oil storage tanks will be constructed near the site of the present one at the Western Transfer shed. The tanks to be built will have a capacity of 55,000 barrels. They are to be built for the Canadian Pacific Railway.

Vancouver, B.C.—Mr. Abraham Grossman is interested in a ten-story structure to be erected in this city. It will be of steel and brick, and cost about $500,000.

Verdun, P.Q.—The Federal Government are planning changes on the river front, where an up-to-date wharf and a properly dredged approach is expected to materialize early in the spring, thus enabling the corporation to complete the dyke and boulevard scheme, that is now practically finished, from the southern limits of the town to this point. Mr. H. Hadley, jr., town engineer.

Victoria, B.C.—A large warehouse being built for Messrs. R. P. Rithet & Co., is nearing completion. It is to be covered with galvanized iron.

BRIDGES, ROADS AND PAVEMENTS.

Niagara Falls, Ont.—The chairman of the board of works and the city engineer, Mr. J. C. Gardner, will visit several near-by cities to inspect the pavement, in order that they will be able to render a report as to which kind of road covering is the most suitable.

Ottawa, Ont.—A deputation waited upon Hon. Frank Cochrane to urge a grant toward the construction of a bridge across the Rideau Canal at Pretoria Avenue. The estimated cost of the bridge, on plans prepared by the city engineer, Mr. N. J. Ker, is $133,500. The land and building damages will total $53,450, making a total of $185,950. A report will be made.

Province of Ontario.—The Ontario Government intend spending an additional million dollars on country roads.

Penticton, B.C.—Mr. H. A. Turner, who has been superintending the surveys for new roads to be opened throughout the Okanagan during the coming summer, has plans for a new steel and concrete bridge which will span the Okanagan River on Fairview Road, near Penticton. Construction is to commence in the early spring.

Thorold, Ont.—The Thorold town council decided to do considerable permanent paving in the near future.

Toronto, Ont.—The Board of Control will advertise for tenders for the year's supply of asphalt. Specifications are to be drawn up by the City Engineer, Mr. Rust.

FIRES.

Guelph, Ont.—$1,000 damage was caused by fire to the biological building of the Agricultural College.

Hamilton, Ont.—The printing and stationery establishment of Robert Duncan was damaged by fire to the extent of $200,000. Several nearby buildings were also damaged.

Owen Sound, Ont.—The Owen Sound Wire Fence Company was lately damaged by fire. Damage is estimated at $3,000.

Parry Sound, Ont.—The ratepayers passed the by-law to bonus the iron works. Major Peuchen, of the Standard Chemical Company, Toronto, is interested.

St. Boniface, Winnipeg, Man.—The sash and door factory of the D. McCormick Company, in St. Boniface, was totally destroyed by fire with a loss of $25,000 in buildings and machinery.

CURRENT NEWS.

Edmonton, Alta.—The building permits of Edmonton and Strathcona for January 1912 amounted to $167,600, an increase of 107.5 per cent. over the corresponding period in 1911. Strathcona is a recent addition to the City of Edmonton.

Fort William, Ont.—The municipal Board of Works are considering appointing a purchasing agent for all supplies not purchased by tender. A. McNaughton, city clerk.

Masset, Queen Charlotte Islands, B.C.—Residents of the town are asking the provincial government for an experimental farm, donkey engines for road work, a large appropriation for road construction, and for assistance for the settlers in draining the large areas of semi-swamp lands.

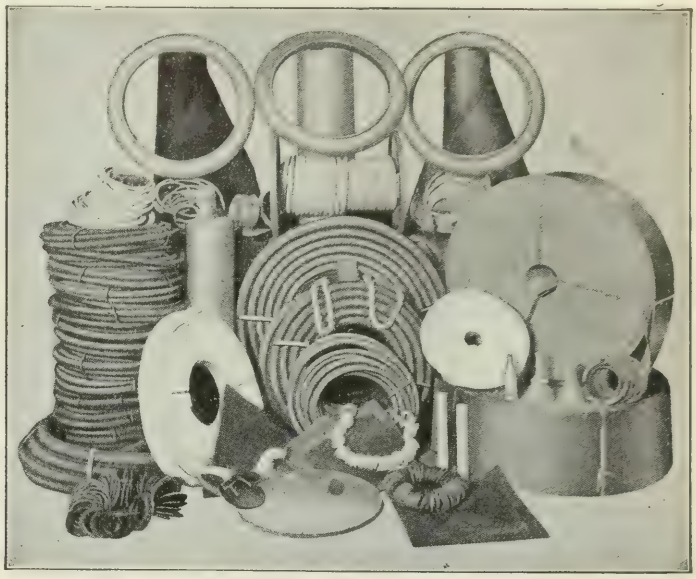
New Liskeard, Ont. — At the Temiskaming Telephone Company annual meeting a report was read which showed that the gross income of the company for 1911 was $32,041.40,

Only Reliable Suction Hose

If you are in the market for **hose,** don't do a thing until you look into the money-saving reasons why you should buy

GOODYEAR Suction Hose

Money-Saving Hose for Contractors, Miners, Dredgers and Others Demanding Hose-Permanency and Hose-Strength.



A Few of the Lines We Manufacture

Longer service, more *stand-up-ability*, greater freedom from constant repairs, would make Goodyear Suction Hose an economy at double the price. But it *costs no more* than the other kinds.

Non-Collapsible—Non-Rotting

Goodyear Suction Hose never caves in. It is built by a process that makes this impossible no matter how long the hose has been in use. It is built around a heavy steel spiral wire imbedded in the inner tube. Tube can't separate from wire nor can dampness reach it. Hence, rust and rot, one of the common failings of other makes of suction hose, is *done away with*.

Suction Hose for Oil and Gasoline

We make rough or smooth bore Suction Hose for all purposes; also a complete line of

Water, Steam and Air Hose

Send at once for our catalog. If you are in doubt as to what kind of hose you need, let our expert help you solve your problem. In all of our business in Canada last year, we had to replace because of slight defects, only $155.22 worth of goods. Write us tonight. (13)

WRITE OUR NEAREST BRANCH

BRANCHES: Montreal—Winnipeg—St. John, N.B.—Vancouver—Calgary—Victoria, B.C., 855 Fort St. Regina, Sask., 2317-2318 South Railway Street — Hamilton, Ont., 127 King Street West.

which compared with the gross income of $31,042.05 for 1910 shows an increase of $999.35. The net ncome for 1911 was $16,416.09, as compared with $15,933.96 for 1910.

Creston Valley, B.C.—A reclamation survey of 40,000 acres of flats in the Kootenay valley, will be made by the provincial government with a view to reclamation. It is estimated that the reclamation work will cost half a million dollars. The survey will take nearly a year.

St. John, N.B.—Mr. William Murdoch, municipal engineer, will offer for sale at public auction on Saturday, February 17th, 12 o'clock noon, one steam dredge and two hopper scows belonging to the city.

Toronto, Ont.—The cost of dredging the River Don from Winchester Street to its mouth, the city engineer, Mr. Rust, reports, would be $200,000, and to construct retaining walls, with twelve foot sidewalks on each embankment $290,000, a total of $490,000. The river bed is full of weeds and muck, and the piling on each side has broken away in many places.

Winnipeg, Man.—A. N. Stokes, president of the British Institute of Architects, has been appointed assessor to award the prizes in the competition for the new Manitoba Provincial Government building plans.

Victoria, B.C.—Mr. Harry Worswick, superintendent of construction on civic works, is arranging for the better and more expeditious handling of his force in the matter of more detailed daily reports of progress on the various works, cost of same, etc.

COPY OF ENGINEER WANTED.

A copy of our issue of No. 1 of volume 17 is required. (The first issue of January 1907.) The usual extension of one month will be made to the party sending in this paper.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA.

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from The Canadian Engineer for small fee.

15844—January 27—Disallowing G.T.R. and C.P.R. tariffs on application Consumers Cordage Co., Ltd., until further order of the Board. Rates on rope.

15845—January 26—Authorizing C.P.R. to construct its Pheasant Hills Branch across thirty-one highways, mileage 202 to 252.92.

15846—January 27—Adding County of Halton party to application of Twps. of Nelson for protection of Plains Road crossing west of Burlington Jct. on G.T.R.

15847—January 25—Authorizing G.T.R. to reconstruct bridge No. 236 over Chateauguay River, mileage 43.82, at Bryson's, Que.

15848—January 25—Amending Order 15498 of November 28, 1911, to read Twp. 10 instead of Twp. 9, C.P.R. Spur Order.

15849-50—January 25—Authorizing C.P.R. to construct spur to premises of Redcliffe Realty Co. and Redcliffe Brick & Coal Co. in Sec. 5, Twp. 13, R. 6, West 4th M., Alberta, and for Quinlan-Carter Co., Ltd., on Lot Subdivision No. 21, in Block "E" of Sec. 17, Twp. 24, R. 1, West 5th, Calgary, Alta.

15851—January 25—Directing C.N.R. within six weeks from date to provide suitable undercrossing on farm of A. J. Hunter, Sleeman, Ont.

15852—January 25—Approving plans and specification of Morden drain to be constructed under track of M.C. Ry. in Twp. of Aldborough, County of Elgin, Ont.

15853—January 31—Amending Order 15802 of January 11, 1912, to read Lot 9, instead of Lot 11, Canadian Copper Co.'s spur.

15854—January 31—Naming express collection and delivery limits for town of Magog, Que.

15855—February 8—Extending for three weeks time for filing plans by C.P.R. for interlocker at Woodstock, Ont., required by Order 15451, November 7, 1911.

15856—January 31—Authorizing Smart-Turner Machine Co., Ltd., to construct travelling crane across G.T.R. siding at Hamilton, Ont.

15857—January 31—Directing that cost of gates at crossing east of Welland Station, Ont., on M.C.R. be borne as follows: 15 per cent. town of Welland, 10 per cent. town of Crowland, remainder by M.C. Ry. See Order 10568, February 26, 1910.

15858—February 1—Disallowing Supplement No. 1 to Boston & Maine Joint and Proportional Class Rate and Commodity Tariff C.R.C. No. 1219.

15859—February 1—Authorizing T.H. & B. Ry. to construct siding into premises of Armstrong Supply Co., Ltd., Hamilton, Ont. Rescinding Order 15745, January 23, 1912.

15860—January 31—Approving revised location of G.T.P.B.L. Co. Cutknife Branch, mileage 31.86 to 55.84, Saskatchewan.

15861—January 31—Directing that town of Simcoe pay G.T.R. 15 per cent. of cost of protection of crossing protection required by Order 15387, November 15, 1911, Norfolk St., Simcoe.

15862—February 1—Authorizing G.T.R. to construct siding into premises of Watrous Engine Works, Brantford, Ont. Rescinding Order No. 15255, October 11, 1911.

15863—Authorizing G.T.R. to reconstruct swing bridge over Richelieu River, mileage 8.75, 13th District, Quebec.

15864-65—February 1—Authorizing C.P.R. to open for carriage of traffic its Moose Jaw Southwesterly Branch near Moose Jaw, Sask., to mileage 27.4, and its Swift Current Southeasterly Branch near Swift Current to Neville, Sask., Mileage, 27.4, speed limit 15 miles per hour.

15866—February 1—Authorizing T.H. & B. Ry. to cross at grade Newport St., Brantford, Ont.

15867-68—January 29—15869—February 1—Approving location of C.N.R. through Twps. 10-11, Ranges 3-4, West 3rd M., Saskatchewan, mileage 25.38 to 51.68, Saskatchewan, and through Twps. 5-6, Ranges 26-28, West 4th M., Alberta, mileage 120.27 to 141.09.

15870—February 1—Approving location of C.N.O. Ry. station grounds at Richmond, Ont., Twp. of Goulbourn.

15871—January 27—15872—January 29—Authorizing C.N.R. to cross thirteen highways with its Calgary Southerly Line, Alberta, and ten highways on its Swift Current Line.

15873—January 30—Authorizing C.P.R. and Montreal Street Ry. to operate over crossing at Papineau Ave., Montreal, without coming to stop, acct. interlocker completed.

15874—January 27—15875—January 31—Authorizing C.P.R. to construct spur for McGillivray Creek Coal & Coke Co., Ltd., near Coleman, Alta., and spur for Nicola Valley Pine Lumber Co., near Canford, B.C.

15876—January 30—Authorizing C.N.R. to open for carriage of traffic its Rossburn Extension from Hamton to a connection with main line east of Canora, 15 miles.

15877—February 1—Approving location of C.N.O. Ry. station grounds in village of Newburgh, Ont.

15878-79—January 27—Approving location of C.N.R. through Twps. 9-6, R. 25, West 4th, Alberta, mileage, 106.37 to 120.27, and through Twp. 52, R. 24, West 4th M., Alberta, mileage 44.40 to 45.97, Province of Alberta.

15880—January 31—15881—January 29—Authorizing C.N.R. to cross with its Grosse Isle Branch, Manitoba, fifteen highways in R. M. Woodlands and with same branch nine highways in R. M. Rockwood, Manitoba.

15882—January 26—Authorizing C.N. Pacific Ry. to use crossing for construction purposes only until June 30, 1912, under further condition that all trains be brought to a stop subject to terms of Order 14577 (C.P.R. Mission Branch crossed by C.N.P.).

15883—January 27—Approving location of C.P.R. station on Yahk Branch five miles north of Kingsgate, B.C., station to be standard portable.

15884—January 27—Authorizing C.P.R. (G.B. & S. Ry.) to construct farm crossing at mileage 25, in Lot 3, Con. 6, Twp. of South Orillia, County of Simcoe, Ontario.

15885—February 1—Relieving C.P.R. from further protection at crossing in the village of Blind River, Ontario.

15886-87—February 1—Approving change in location of C.P.R. stations at Ste. Rose, County Laval, Quebec, and at St. Martin Jct., Parish of St. Martin, Quebec.

15888—February 2—Authorizing C.P.R. to construct spur for Construction & Paving Co., North Toronto, Ont.

15889-90—January 30—Authorizing C.P.R. to use and operate bridge over Scugog River, near Lindsay, Ont. (G.B. & S. Ry.), and to use and operate ten bridges on G.B. & S. Ry. between mileages 20.64 and 81.13, Ontario.

15891—January 30—Authorizing C.P.R. to operate its trains under bridge 4.37, Walkerton S.D., Ontario.

15892—January 27—Authorizing C.P.R. and G.T.R. to use and operate crossing of G.T.P.B.L. Co. crossing C.P.R. Pheasant Hills Branch account interlocker completed, Saskatchewan. See Order 11627, September 9, 1910.

15893—January 27—Certificate of correction to G.T.P.B.L. Co. plan of location Tofield-Calgary Branch.

15894—January 29—Authorizing G.T.P.B.L. Co. and C.N.R. to use interlocking plant at crossing in N.E. ¼ Sec. 20, Twp. 38, R. 26, West 2nd, at Dana, Sask.

15895—January 29—Directing Pere Marquette Ry. to erect and maintain fences in middle part of Lot 14, Con. 2, Colchester South, owned by James Murray, County of Essex, Ontario.

15896—January 31—Authorizing Twp. of Gloucester, County of Carleton, Ont., to construct Queen Mary St. over tracks of C.P.R. (Prescott S.D.).

15897—February 2—Authorizing C.P.R. to open for carriage of traffic its second track from Romford Jct. to Crete, on Cartier S.D., Ontario.

15898—February 3—Approving location of Lake Erie and Northern Ry. from Grand River in city of Brantford to village of Port Dover, in County of Norfolk, Ont.

15899-15900—February 1—Approving standard clearance of G.T.P. Ry. coal chutes, also for new ice house for use on side tracks.

15901—January 1—Relieving C.N.R. from further protection of highway between mile post 475 and 476 east of Aberdeen, Sask.

15902—January 30—Amending Order 15692, December 27, 1911, by providing that bell be installed before June 29, 1912. C.P.R.

15903—February 5—Extending until March 15, 1912, time for installation by G.T.R. of interlocking plant at Nipissing Jct. crossing C.P.R. to connection with T. & N.O.

15904—February 6—Approving revised location of C.N.O. Ry. through Twp. of Loughborough, County of Frontenac, mileage 164.59 to 164.76.

15905-06—January 27—Authorizing C.N.R. to cross public roads (two) on its Grose Isle Branch, in R.M. Rockwood, Manitoba.

15907—February 5—Authorizing C.N.R. to cross with its Strathcona-Camrose Branch seven highways in Alberta.

15908—February 6—Further extending until June 30, 1912, time for completion by C.P.R. of work required by Order 10462, May 3, 1910.

15909—February 6—Authorizing C.N.R. to construct spur line from its Vegreville-Calgary Line into premises of Rose Deer Coal Mining Co., Ltd.

15910—February 7—Amending Order 15709 of December 29, 1911, by striking out word "two" and substituting word "three."

15911—February 5—Authorizing C.P.R. to construct across and divert highway at mileage 210.03 at west boundary of Sec. 18, Twp. 18, R. 16, West 3rd M., Saskatchewan.

15912—February 7—Authorizing C.P.R. to construct spur in Moose Jaw, Sask., for Saskatchewan Flour Mills Co., Ltd.

15913—February 6—Amending Order 15816, January 17, 1912, by adding words "and registered in the Land Titles Office for the North Alberta Land Registrar under No. 5010 Day Book A.1" at end of recital to said Order.

15914—February 6—Authorizing V.V.E. & N. Co. and Vancouver, Fraser Valley & Southern Ry. Co. to use and operate crossing near Ardley, B.C., account interlocker completed.

15915—February 5—Dismissing application of city of St. Thomas, Ont., to construct Inkerman St. across G.T.R.

15916—February 5—Removing speed limitation on G.T.P.B.L. Co. Yorkton Branch from Melville to Canora, Sask. Order 14241 dated July 17, 1911.

The Canadian Engineer

An Engineering Weekly

THE ZINN BUILDING.

By T. KENNARD THOMSON, Consulting Engineer.

The Zinn Building is located at the southeast corner of 25th Street and Eleventh Avenue, and is a fine 11-story structure designed for and built by the Simon Zinn Company, manufacturers of fancy metal goods, as well as private offices, requiring, therefore, very heavy floor construction, the floors being designed for 250 pounds live load per square foot. About three-quarters of the basement is on the street level, while the engine room floor was carried down to 11 ft.

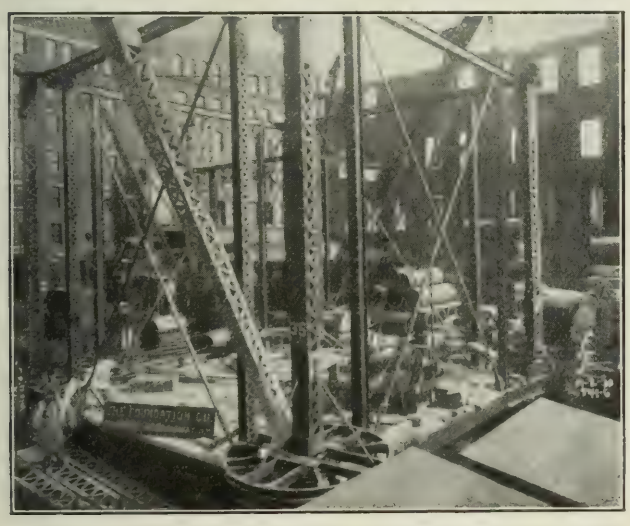

Fig. 1.—Four-Masted Steel Derrick.

2 in., and the boiler room and coal vaults to 15 ft. 2 in., the latter being under the 20-foot side walls on Eleventh Avenue, the lot being about 100 ft. by 100 ft.

This building leads the way for a radical improvement of the buildings in this valuable neighborhood.

In September, 1910, the writer reported to Messrs. Edward I. Shire and Lewis R. Kaufman, the architects for this building, his opinion on the proposed plans for the foundations, having previously received from the architects the results of the wash borings taken by Messrs. Phillips & Worthington. The two following tests give a good idea of the sixteen borings that were made:—

Test No. 2.—Zero equals 2 in. above curb A:

0′	0″	to 9′ 6″	Fillings.
9′	6″	to 31′ 0″	Sand and gravel.
31′	0″	to 43′ 4″	River mud.
43′	4″	to 45′ 4″	Sand and gravel to rock.

Test No. 8.—Zero equals 5 in. above curb:

0′	0″	to 17′ 4″	Fillings.
17′	4″	to 33′ 8″	Sand and gravel.
33′	8″	to 50′ 2″	River mud.
50′	3″	to 67′ 10″	Medium sand to rock or boulder.

In short, the site was "made ground" over the river silt, or mud, the filling consisting as usual of a little bit of everything, including boulders, sunken timbers, &c., which we afterwards found to be correct.

The "filled in" portion extended from the street level down to from 8½ to 18 feet below the curb, while the borings indicated that the river mud or silt extended from 14 ft. 8 in. to 33 ft. 6 in., or a variation of nearly 17 feet. It is not conceivable that the river silt was originally so much out of level, so the inference is that the sand, &c., sank into the silt, displacing it in places and forcing the adjoining portions to a higher level.

This is the regular Hudson River silt, and is a very much more treacherous material than the so-called New York quicksand which overlies the hardpan in the whole lower portion of Manhattan Island.

Under these circumstances the writer was very strongly of the opinion that the only really reliable foundation for this building would be pneumatic caissons, and the way the caissons acted while being sunk confirmed this opinion most decidedly.

Fig. 2.—Showing Two Four-Masted Steel Derricks. Steel Forms used for Building up Cylinders—Collapsible Steel Shafts Inside of Steel Forms. Wooden Cofferdams, Used where Concrete Stopped Below Ground. Pile of Cast Iron Blocks Marked "B" Used for Weighting Down Caissons. Each Block Weighs 1½ to 2¼ Tons.

In addition to the very treacherous nature of the soil that repeatedly "held a caisson up" and let it drop to the deck without warning, there is the fact that a subway will probably be built up Eleventh Avenue some day, which would tend to lower the water below the tops of any wooden

piles. The writer, having previously underpinned a building which had been built on piles 30 feet long, which, when cut off and capped, were entirely under standing water, but after the construction of a railroad tunnel were found to be free from water from top to bottom. It is well known, of course, that wooden piles have lasted for centuries in good condition when driven in water-bearing soil and kept submerged, but that the same piles would rot very quickly if the water were drawn off.

Besides, it would be almost impossible to drive wooden or concrete piles to rock on account of the sunken timbers, boulders, &c., which were indicated by the borings and afterwards removed through the air chamber of the caissons without going to such expense that there would be very little difference between the cost of the pneumatic caisson and the less reliable foundations.

The owners, therefore, decided to use caissons and accepted the tender of the Foundation Company for thirty-four circular caissons to be carried to bed rock for the lump sum of $82,500, which sum included the engine and boiler rooms and coal pocket walls, floor, &c., below the curb line.

There are 15 caissons of 6′ 6″ diameter
3 " 6′ 10″ "
7 " 7′ 6″ "
8 " 8′ 0″ "
—
or 34 in all

These caissons all had a steel working chamber, sides and roof, ⅜-inch thick.

The concrete being started on the top of the roof or deck, was built up about 20 feet at a time inside of removable circular metal forms. As soon as this concrete had set hard, excavation and sinking would be started and carried

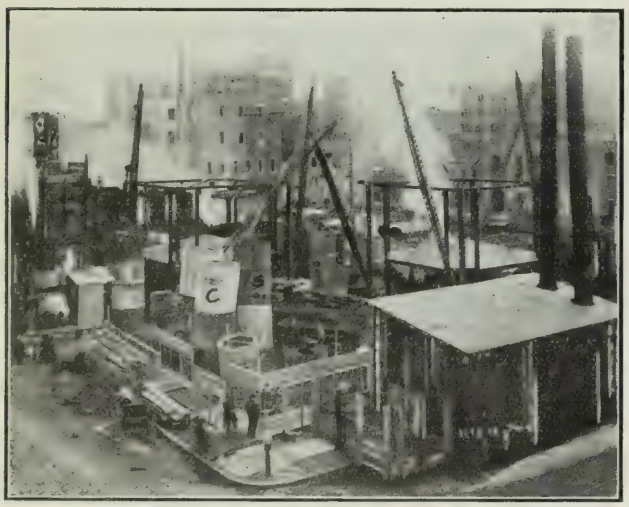

Fig. 3. Showing operation on November 15, 1910, also concrete mixer. "S" steel "Form" or shell removed before sinking. "C" Wooden Cofferdam.

on until the top of the concrete had nearly reached the surface of the ground when the men would be taken out and placed elsewhere while another "build up" of concrete was being put on. The pumping of compressed air had to be kept up of course all the time; the necessity for which was shown when the gauge tender allowed the air pressure to lower, which resulted in the air chamber being filled with sand to the deck when the cutting edge "ran away," of which more will be said later.

The working shaft for men and material was also formed by collapsible shafts which, however, were left in place until the sinking was finished and the air chamber had been filled with concrete, so that nothing but concrete was left from the deck to the base of the column base or grillage. The concrete was made of one part of Portland cement, three parts of sand, and five parts of broken stone or gravel.

Some trouble was experienced in getting the concrete to set up quickly, due partly to the season of the year and other causes. The concrete eventually set up hard but caused more or less delay waiting for it to do so before sinking could be resumed. Considerable sand was used from the Woolworth Building, Broadway and Park Place;

Fig. 4. Showing work on December 29, 1910, with grillage on Caisson in foreground.

this sand contained more or less clay and other impurities but gave a higher tensile test than the finer "Cowboy" sand.

Dr. Charles F. McKenna made the chemical and tensile tests and reported in favor of the Broadway sand.

The contract was let on October 8th and work at once started, although some of the old buildings had not been entirely removed.

The caissons were sunk in the following order:—

No. 1	sealed on	November	21st	at a depth of	—42.5 feet.

The only remarkable or unique feature of this job was the number of times the caissons ran away—or got beyond control and sank in the silt up to the deck. This happened so often that whenever a caisson was undermined, ready for sinking, the entire gang came out instead of staying in the air chamber as usual. Otherwise there would have been much loss of life.

This resulted in a loss of about 8 or 10 hours each time, as it, of course, took time to send a man down the shaft with a pail to clear away enough material to make room for the bucket and gang.

The following are the caissons that ran away:—

Caisson No.	33—Dec. 1st, 1910

Fig. 5. On December 21, 1911, showing grillage concrete in place.

Caisson No. 34 on December 10th sank suddenly while an inclined timber brace was in position. This brace toed against Caisson No. 30 and was acting against the top of No. 34. The result was that No. 34 was broken in two about 8 feet below the ground, or 35 feet above the cutting edge, requiring the removal and rebuilding of the upper portion which was, of course, then as good as the original; the cost of the accident being borne by the contractor, as a matter of course.

A new method of filling the working chamber was proposed and adopted by the writer in view of his experience in removing caissons already sunk where he had found that concrete "benched" and therefore put in rather dry was very poor, and concrete put in very wet was apt to shrink from one-half to one inch leaving a space between the deck and concrete.

This shrinkage appears to go on for 12 to 18 hours while the concrete is setting and drying, so on the Zinn Building he had the concrete placed in the working chamber as wet as possible up to about 10 inches of the deck and then allowed to set under air pressure for about 15 hours, when the

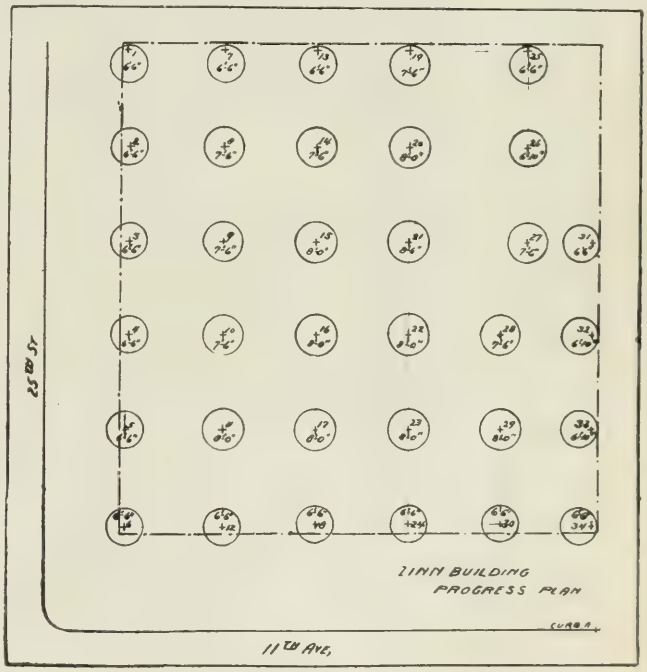
Fig. 6. Showing Wooden Cofferdams on Caissons on south-west corner.

lock was taken off and wet grout dumped from the top of the shaft, followed rapidly by very wet concrete.

This is the cheapest and best way of filling the working chamber—the only care required is to see that there are pipes or other means of escape for the air under the deck.

The compressed air should be left on for at least 18 hours and the concrete pushed as rapidly as possible after taking the air off.

As already intimated, the building was built by and for the Simon Zinn Company, whose architects are Messrs. Edward L. Shire and Lewis R. Kaufman.



Progress Plan.

The Hay Foundry Company erected the steel work, and the Foundation Company the caisson and foundation work, and Jacob Zimmerman was the general contractor; the writer being the Consulting Engineer to the owners on the foundation work.

SUBMERGED CONCRETE WORK.

A method of constructing submerged concrete work which is required to sustain heavy loads, has been brought forward by Mr. J. H. Tromanhauser, of Toronto. In this article we present a method of constructing light-house foundations, etc., by this method, which is suitable for exposed situations.

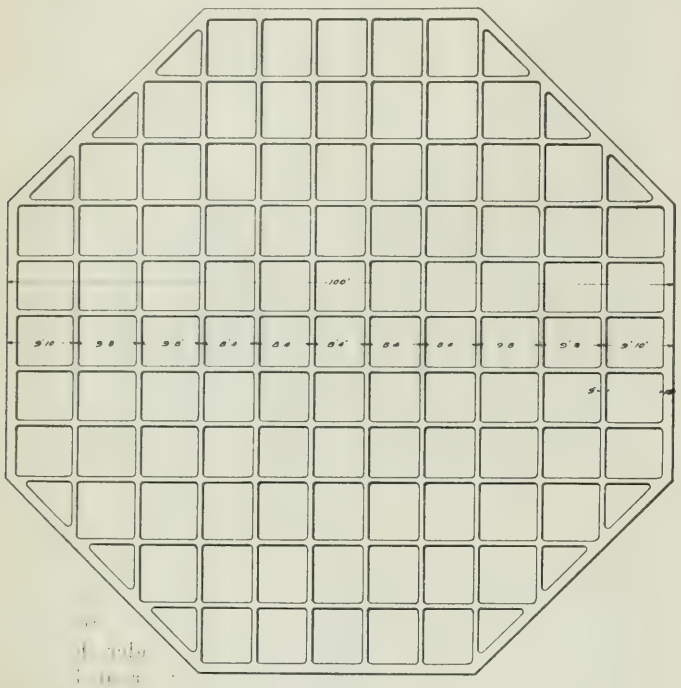


Fig. 1.

This method is an advance over the previous means of erecting acqueous concrete work in as much as varying depths do not greatly increase the difficulties of construction. The structure is erected on the nearest convenient shore, and, when sufficiently set, is skidded into the water and towed to the desired spot. When the wooden bottom is removed the honeycombed structure sinks.

This pontoon may be made to any depth to suit the depth of water. The displacement of this pontoon per foot submerged = 8,318 cubic feet = 260 tons at 62½ pound water pressure.

This foundation may be towed into position, and sunk securely upon the sea bottom so quickly that it is hardly possible to conceive conditions of tide, cave or wind, where this could not be successfully accomplished.

Usually, the sea bottom is so near a good general level, and also, so compact, that in most cases, this wide structure could be safely sunk directly upon the natural bottom without any artificial preparation whatever. This is frequently done with wooden cribs for lighthouse and other foundations, and with a heavy, thoroughly-bridged concrete structure the work of building, sinking and ballasting would be simple, safe and economical, compared with the same operations with any other materials or methods.

In case the natural sea bottom was such as to render it unsafe for supporting the structure, then, of course, an artificial support would have to be built, but just what methods should be followed in the construction of the foundation, is a question which could only be determined after a full and complete knowledge of all the local conditions has been ascertained.

The design of foundation here illustrated, will float with about 52 per cent. of the height of its concrete walls above the surface. Therefore, a structure with walls 50 ft. high may be built and floated into position in less than 25 ft. of water. This means that a concrete section designed for a 40 ft. depth of sea can be built in 25 ft. of water, and still have 10 ft. of its walls projecting above the surface to allow for settlement into the sand and mud after the pontoon floor has reached contact with the sea bottom.

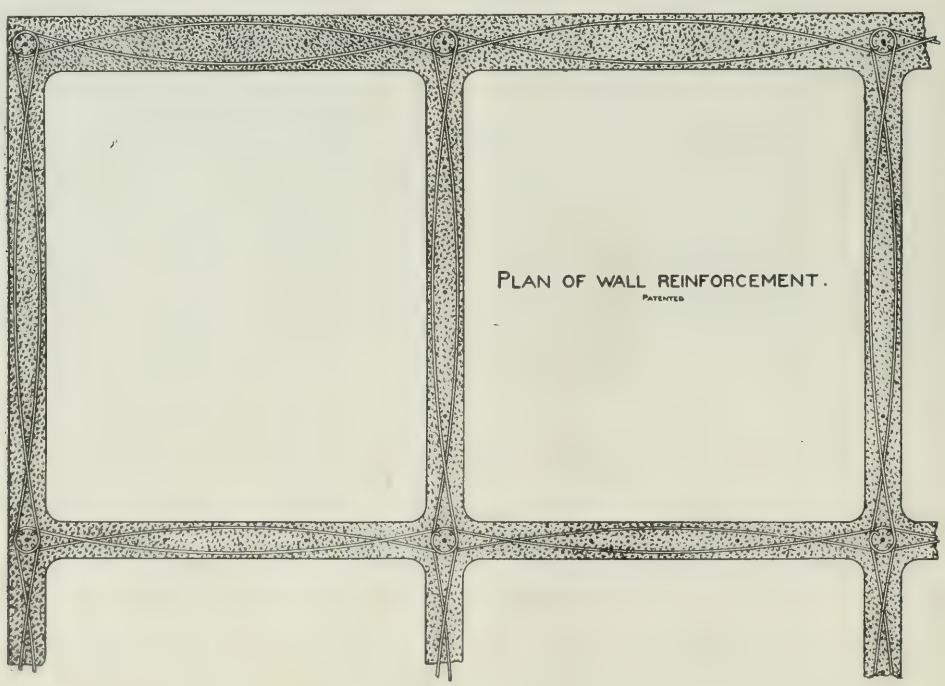

Fig. 2.

Fig. 1 is a top view of Mr. Tromanhauser's patent pontoon. This is octagonal in shape, one hundred feet across. A water-tight wooden bottom is secured to the lower end.

Fig. 2 shows the method of placing the reinforcement steel in the compartment walls, and Fig. 3 represents a stack of the wall truss bars bent to shape ready to be built

into the concrete. These bars are of square steel, with the ends bent in hook shape to give secure anchorage in the concrete. They are built into the walls in pairs, as shown in Fig. 2, and give the walls not only great bridging strength, but also truss them both ways against side or lateral strains.

The size and spacing distance of the truss bars would depend upon circumstances, as a structure for deep water would need greater strength than one for shallow depths, but in all cases the walls must be built or trussed to resist lateral strains from both sides, for, when the concrete sections are floating the outer walls are exposed to a heavy in-

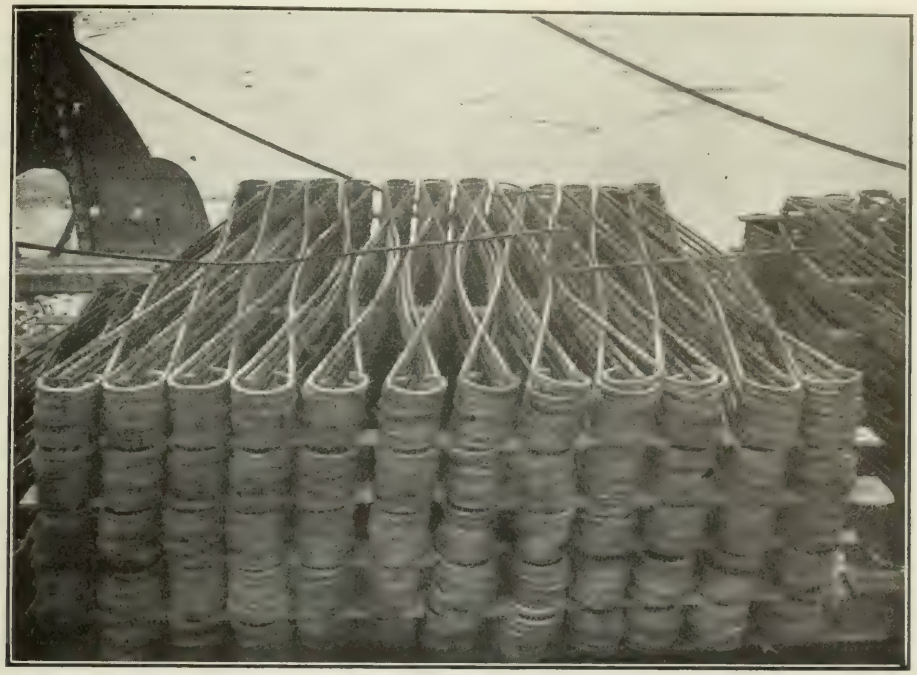

Fig. 3.

At all intersections of the walls the hooked ends encircle vertical round steel bars, which feature practically links the entire wall structure into an unbroken chain of reinforcement.

ward hydrostatic pressure, but when sunk and filled with ballast and water, this is reversed and the heaviest pressure is from the inside. The system of reinforcement is fully covered by patents.

THE GROWTH OF THE WEST.

The end of a calendar year, as a rule, is a signal for municipalities to strike and publish a balance. A compilation of municipal and provincial statistics of such items as are of interest to the engineer will show in a tangible manner the growth of Western Canada.

According to the official figures issued by the census commissioner, the population of Western Canada has increased in ten years 174 per cent., as compared with an increase of 17 per cent. in the East. Of the western provinces Alberta has made the greatest gain; Saskatchewan is a very close second and British Columbia and Manitoba both have records that compare favorably with any eastern province. In the decade under review the eastern half of the Dominion has added to its population 721,722 souls as compared with 1,045,717 by the west. Saskatchewan has added the greatest number and of these most of them belong to the farming community which speaks well for the future of that province. The following table shows the changes in population within the period 1901-1911 by provinces divided into eastern and western sections:

West—	1911.	1901.	Increase.	Per cent.
Alberta	372,919	73,022	299,897	424.0
British Columbia	362,768	178,657	184,111	103.0
Manitoba	454,691	255,211	199,480	80.0
Saskatchewan	453,508	91,279	362,229	386.0
	1,643,876	598,169	1,045,717	174.0
East—				
New Brunswick	351,815	331,120	20,695	6.0
Nova Scotia	461,847	459,574	2,273	0.0
Ontario	2,529,902	2,182,947	346,955	13.0
Prince Edward Island	93,722	103,259	—9,537	—
Quebec	2,000,697	1,648,898	351,799	21.0
	5,437,983	4,725,798	721,722	17.0
Total for Canada	7,081,869	5,323,967	1,767,439	33.0

Twelve representative cities of the Canadian West show a gain of population within five years of 93.6 per cent. and a gain in ten years of 301.5 per cent. These are official figures and do not include all the people that, properly speaking, belong to the community of which the cities named constitute the real city centre. Edmonton's figures for instance do not include Strathcona, which is practically a part of that city. Those of Winnipeg do not include the populous suburbs of St. James, St. Boniface, Norwood and other communities that adjoin its borders. Strictly speaking, therefore, the actual increase of the urban population is greater than the figures represent.

In the case of practically every city, with the exception of Regina, complaints are made as to the inaccuracy of the official figures. Municipal censuses have been taken which show larger populations, but inasmuch as the complaints are general, and that municipal recounts have not been made in every case, the official figures have been used to

show the growth taking place in western cities, as exemplified in the table following:—

	1901	1906	1911	5 yrs.	10 yrs.
Brandon	5,620	10,408	13,837	32.9	146.2
Edmonton	2,626	11,167	24,882	122.8	847.5
Calgary	4,091	11,976	43,736	265.1	969.0
Fernie	1,873	3,913	3,140	*19.6	66.6
Lethbridge	2,072	2,313	8,048	247.9	288.4
Medicine Hat	1,570	3,020	5,572	84.9	254.9
Moose Jaw	1,558	6,249	13,825	121.2	787.4
Portage la Prairie	3,901	5,106	5,885	15.2	50.8
Prince Albert	1,785	3,005	6,254	108.1	250.3
Regina	2,249	6,169	30,210	389.7	1243.2
Saskatoon	113	3,011	12,002	298.6	10521.2
Winnipeg	42,340	90,153	135,430	50.1	219.8
	75,418	156,490	302,827	98.6	301.5

* Decrease—due to miners' strike.

An increase in population always precedes an increase of building, and the quality of the building, structural and architectural, depends upon the monetary standing of the erectors.

With an increase of 174 per cent. in population during the past decade, has come an increase of 51.12 per cent. in building operations in five years in the western sections. This increase is made up thus:—

	1907	1908
Brandon	$ 704,209	$ 293,047
Calgary	2,094,264	1,004,520
Edmonton	2,280,210	2,549,847
Fernie	250,000	250,000
Lethbridge	205,000	369,145
Medicine Hat	150,000	138,072
Moose Jaw	546,424	430,925
Portage la Prairie	257,875	120,000
Prince Albert	300,000	200,000
Regina	1,177,840	516,656
Saskatoon	277,211	115,625
Winnipeg	6,309,950	5,513,700
Total	$14,553,064	$11,501,037
Compared with previous year per cent...		— 20.91

+ Increase. — Decrease.

This enormous increase and migration is due to a large extent to the railway companies which are opening new districts with the extension of their steel. The figures of mileage increase for three provinces are as follows:—

Year	Manitoba	Saskatchewan	Alberta
1893	1,470	748	807
1894	1,471	965	807
1895	1,472	965	807
1896	1,470	965	807
1897	1,570	965	807
1898	1,592	965	807
1899	1,603	993	908
1900	1,815	993	908
1901	2,056	1,107	978
1902	2,128	1,102	978
1903	2,224	1,117	978
1904	2,364	1,180	1,020
1905	2,672	1,523	1,020
1906	2,823	1,973	1,200
1907	3,074	2,025	1,323
1908	3,110	2,081	1,323
1909	3,205	2,630	1,323
1910	3,526	3,350	1,774
1911	3,796	4,202	2,111

The increase in mileage of the various companies for two years reads thus:

1910	Man.	Sask.	Alta.	Total
Canadian Pacific Railway	1,529	1,750	1,270	4,549
Canadian Northern Railway	1,531	1,183	219	2,933
Grand Trunk Pacific	304	417	285	1,006
Great North	162	.....	.....	162
Total	3,526	3,350	1,774	8,650
1911				
Canadian Pacific Railway	1,595	2,041	1,273	4,909
Canadian Northern Railway	1,735	1,610	393	3,738
Grand Trunk Pacific	304	551	445	1,300
Great North	162	.....	.....	162
Total	3,796	4,202	2,111	10,109
Increase of 1911 over 1910	470	852	337	1,459

The Canadian Northern Railway has had a wonderful season of construction this past year. Four thousand four hundred and fifteen miles of Canadian Northern lines are now in operation west of the Great Lakes, and some additional lines are ready for operation as soon as inspection has been made by the railway commission. In the past summer 16,686 men were employed in Canadian Northern construction west of Port Arthur.

1909	1910	1911	Change
$ 350,120	$ 1,224,385	$ 1,108,129	— .094
2,420,450	5,589,594	12,709,478	+ 127.39
2,128,161	2,161,356	3,797,525	+ 75.70
1,374,700	325,000	150,000	— 53.84
1,268,215	1,211,310	1,033,980	— 14.69
228,168	427,140	450,000	+ 5.38
512,440	1,071,090	2,475,736	+ 131.09
195,000	362,500	300,000	— 17.12
141,810	662,475	921,145	+ 39.12
744,479	2,416,288	5,088,110	+ 110.59
1,002,055	2,817,771	4,920,000	+ 74.65
9,226,325	15,116,450	17,600,000	+ 15.77
$19,591,923	$33,385,359	$50,554,103	
+ 70.34	+ 70.41	+ 51.12	

Allowing an average wage of $2.50 per day the Canadian Northern Railway would have a monthly pay roll for these men of over one million and a quarter dollars. Every contract on the system from Montreal to Port Mann, opposite Vancouver and Batlott Sound, on Vancouver Island, has been let, and work has commenced on practically every section of the main line. Work on the section from Port Mann to the Yellow Head Pass will continue throughout the winter of 1911-12.

A great deal of winter work will also be carried on between Port Arthur and Sudbury on the eastern section.

It is difficult to compile figures of the standing of private concerns; although on the contrary companies of a semi-private nature, especially those dispensing public commodities are available. Of these are published the annual revenue from public water companies for four years operating in the western provinces:—

	1908.	1909.	1910.	1911.	Increase 1911 over 1910.	P.C.
Brandon	$ 38,819	$ 41,000	$ 34,650	$ 69,572	$ 34,922	100.93
Calgary	50,938	60,269	108,500	204,500	96,000	88.48
Edmonton	.....	.....	75,167	117,748	42,581	56.69
Fernie	.....	.....	20,500	17,804	2,696	13.15
Lethbridge	25,342	30,113	44,615	39,164	5,451	12.22
Moose Jaw	9,865	11,862	21,622	29,434	7,812	36.17
Portage la Prairie	14,031	17,623	26,780	36,061	9,281	34.76

Regina	28,723	32,000	31,000	36,432	5,432	17.52
St. Boniface	7,627	8,845	11,340	13,500	2,160	19.11
Winnipeg	388,200	387,303	404,100	416,854	12,754	3.14

FORESTRY COMMISSION OF BRITISH COLUMBIA.

Owners of British Columbia timber will be interested in the legislation recently introduced in the legislature of that province, and based on the recommendations of the Forestry Commission made a year ago. The new policy is complete in detail and contains many and important departures from the present Act. The first great impetus was given to lumbering in British Columbia when the coalition government of 1901 prohibited the export of unmanufactured timber. This law worked out so well that it was adhered to, and Hon. W. R. Ross, in moving the second reading of the bill in the British Columbia legislature, thought so well of it that he declared it was a measure of the McBride administration. Premier McBride did not assume power until 1903, by which time the Americans were erecting mills in British Columbia, since they could not take the timber across the boundary line.

Features of the proposed legislation are as follows: Abandonment of the old method of staking. Hereafter, when timber is to be disposed of, a cruise will be made and tenders called for. Bonuses on licenses will be fixed according to conditions, principally at so much per thousand feet in addition to royalties. Existing timber leases when renewed will have new terms imposed in view of the terms and conditions imposed on other holders of timber so as to effect equality.

Timber held under license must all be surveyed by March 13th, 1918. If owners do not observe due diligence, the government may cause the survey to be made, charging owners therefor. Pulp timber concessions will remain the same until renewed. The licensing system will be retained, but conditions are altered. Terms are more favorable than in the case of timber for sawmill purposes.

Provisions are made for the creation of a forest reserve for the purpose if reforestation. Present scaling prices are interfered with. In districts where there are no official scalers, it is provided that unofficial scalers may be examined and licensed. No change is made in respect to timber marking and the manufacturing of timber within the province.

Special provisions are made for clearing away debris around camps, mines, mills, engines, and on rights-of-way of telephone, telegraph and other lines. All dangerous accumulations of debris must be disposed of, that forest fires may be prevented.

Logging operators may be required in the case of dangerous slash to make special provision for the prevention of fire when the minister requires it by cutting out fire lines. In respect to railways, a safety zone on either side is created to the width of two hundred feet, which must be kept clear of all combustible material. If this requirement is not observed, the government may do it, charging the expense to the company.

A forest fire protection fund is to be created. Owners will contribute a cent an acre, in addition to two and a half cents per thousand feet cut, against which the government will contribute dollar for dollar. Crown granted lands which do not pay royalty, are required to pay two cents an acre. Arrangement is made for automatic assessments for any time when the fund might prove inadequate. If the fund is too large, proportionate reduction will be made.

Railway tracks must be patrolled after the passing of each train, railway companies to bear the expense. A force of fire wardens must be maintained by companies during the construction of railway lines, and before running operations can be begun certificates must be obtained that debris has been cleared from the right-of-way. In case of fires started by railways through negligence a fine not exceeding one thousand dollars may be imposed. Provision is made for the use of preventive devices in the case of logging engines, locomotives, steamboats, portable engines, etc.

Contributors to the regular fund for fire protection who are placed at extra expense for protection and in fighting bush fires are recouped by the government to the extent of one-half the expenditure.

In regard to hand-loggers' licenses, the minister may be authorized to grant such in districts in which injuries to Crown or other timber lands is not likely to result, subject to certain exceptions. Classified increases have been made in the royalties on lumber cut in the province and intended for export. Otherwise royalties will be the same as at present.

Although the new timber policy has been announced but a few days, the Mountain Lumber Manufacturers' Association has taken prompt action. Fourteen members of the Association conferred with the lumber manufacturing colleagues on the coast, and asked the government to delay final consideration that they might be heard in regard to certain points of the bill.

The services have been secured of Mr. Overton Price, vice-president of the National Conservation Association of the United States, to assist the British Columbia Government in supervising the reorganization of forestry matters during the coming summer. Mr. Gifford Pinchot will also go to British Columbia if possible.

GOOD ROADS MEETING.

A convention of representatives of the various good roads associations of the Province of Ontario will be held in the York County Chambers, Adelaide Street, East, on February 26 and 27, for the purpose of formulating definite plans for road systems. The representatives will wait upon the Ontario Government during their stay in Toronto.

COST OF CONCRETE SEWERS.

By Victor Windett.

From a Paper Read Before the Western Society of Engineers.

A REINFORCED CONCRETE FACTORY.

Recently at Cambridge, Mass., there has been completed a right-triangular shaped reinforced concrete factory, owned by the Cambridge Factory Trust, and occupied on the two upper floors by A. B. Smith & Company, manufacturers of cigars. The lower floor is occupied by stores. It will be noted from the accompanying illustration that the exterior of the building has a very dignified and refined appearance, while the interior is arranged for maximum efficiency. The design was made in accordance with plans and specifications of Monks & Johnson, architects and engineers, 7 Water Street, Boston, and the type of construction was adopted on account of its fitness for close quarters and other reasons. Mill construction was not considered.

Exterior View of Factory.

The engineers made estimates using both of these types of concrete construction and adopted the column and flat slab system, for it was found as cheap as the beam and girder type, besides offering the additional advantages of simpler forms, lower cost of automatic sprinkler installation, and better overhead shafting facilities. The forms for a beam and girder system would have been very complicated owing to the triangular shape of the building.

The factory is three stories high, with basement, with all floors and the frames of reinforced concrete, while the exterior between the pilasters is veneered with 4-inch red sand-struck brick. The longer side of the building is about 151 feet while the shorter sides are 87 feet and 132 feet. The lower floor is devoted to stores, with entrance on Massachusetts Avenue. The upper floors are devoted to cigar manufacturing, the entrance to these being by a stairway and an elevator in the right-angled corner of the building.

The general impression that reinforced concrete structures have a displeasing effect is being diminished by such structures as this Cambridge cigar factory. The lines of the building are exceptionally well kept, the height seeming more than it really is, due to the continuation of the pilaster lines to the top. This is effected by means of corbels and small marble panels at the top. The entire width between the pilasters is taken up by the large window area, beneath which is 4-inch brick veneering with concrete panels in the centre and below each of the four respective windows. The entire cornice is of concrete, while a concrete coping rests on the 8-inch thick brick wall running around the top of the building. The artistic effect is excellent, and the building is a very creditable addition to the community and would not be recognized as a factory.

The interior arrangement of the building has been planned for maximum efficiency. All of the floors are of 7-inch concrete, the first floor having a terrazzo finish. There are three rows of columns on each floor running parallel to the long side of the building with 18-feet bays each way. The window area is about 75 per cent. of the wall area, this being secured with windows 7 feet 6 inches high running up to the floor slab. The windows have wooden frames and sashes and are pivotted at the top, while the lower portions are double hung. The general width of the window is 15 feet 10 inches. An automatic sprinkler system is installed throughout the building. The columns rectangular in cross section vary from 20 inches to 30 inches in the basement and first floor, to 16 inches by 30 inches on the second and third floors. The basement columns are reinforced by twelve 1-inch diameter rods with ¼-inch hoops placed 12 inches on centres. The reinforcement of the first, second, and third floor columns consists of ¾-inch rods, eight being in the first floor columns, and this number decreasing by two for each successive floor. Hoops ¼-inch diameter are also spaced similarly to the basement columns.

The reinforcement of the floor slab consists of a layer of rectangular rods at the top and a layer of diagonal rods at the bottom, the latter having a slight lap. The rectangular rods lap over column heads with laps ranging from 5 feet 4 inches to 8 feet 4 inches. This method is slightly different from the ordinary, and avoids four layers common in most flat slab systems. The floor load was estimated at 125 lbs. per square ft., and the mixture of concrete used at the column heads was quite rich, being 1:1-1/2:2. It is stated that a saving in steel was made by this method.

Interior View of Factory.

The entire building, which was designed with the future intention of putting on another storey, rests on concrete footings placed on hard pan. These footings are generally 9 feet 6 inches by 8 inches. The elevator well is of terra cotta, while the chimney is of brick, and at present there is a temporary roof of wood with plastic slate.

Although this building might properly be stated to be "absolutely fireproof" a serious loss might occur by the burning of the combustible contents. To prevent such an occurrence about 340 Grinnell automatic sprinklers have

been installed on a wet system put in in accordance with specifications of the General Fire Extinguisher Company of Massachusetts. The interior view shows clearly the method of suspending the sprinkler pipes, and the advantage gained in this connection from using a flat slab system.

The entire building was erected by the Concrete Engineering Company of Boston, in accordance with plans and specifications of Monks & Johnson, the architects and engineers. The concrete was mixed on the ground in a 1-yard Ransome mixer that discharged directly into Ransome dump buckets which were hoisted to the top of the wooden tower where the concrete was chuted directly to the forms.

PIPE SYSTEMS IN STREETS.*

By Charles E. Bolling.

The purpose of this paper is to call attention to pipe systems in streets in connection with roadway improvements.

At this period of progression, when so many people are aroused and interested in the advancement and improvement of our country, not confined to localities, but extending over the whole of the United States; when the attention of our progressive citizens is being attracted to the many and various plans and schemes for greater development of our resources, as shown by numerous conventions and assemblies where we are enlightened by many instructive and able articles and discussions upon the different subjects for our further development, I feel confident that no one subject has more aroused the interest of the people than the importance and necessity of constructing highways, roads and streets.

Much valuable information and instruction has been freely given as to the making and maintaining of good roads and streets. It appears to the writer of this article that some important economical features in road construction have been overlooked and have not received proper consideration. Therefore, as briefly as possible, I shall call attention to what I regard, after many years of experience, as being in the line of economy in road construction and maintenance, which is, as the title of this paper shows, the necessity of underground pipe construction before making streets and roads. Especially do I regard it as being worthy of consideration in growing cities, towns and suburban sections. No matter how carefully a road or street may have been built, it is destroyed and ruined subsequently by the introduction of pipes, such as sewer, gas, water, etc., and their connections, and whenever installed the results are a series of ruts and mounds in the street. I have never seen a street properly repaired after being cut up for pipes.

In communities that are improving and developing, the first cry is for good roads. Then later follows the demand for water, sewerage and light. After a while these necessary improvements are made—most often at long intervals. With each pipe construction the street is cut into, again injured, and finally has to be entirely reconstructed. It is recognized that all of these conveniences are paid for by a tax upon the property abutting the street, whether the improvements are made by the city, or town, or by a private company, and, whenever a section is sufficiently built up to demand these necessities and comforts, sewer and pipe lines are constructed and connections made to the improved or occupied lots scattered along the line of the highways. The vacant lots usually do not have the connecting pipes from the main lines extended to them. And then connections are made for sewer, gas and water, from time to time, as each lot is built upon. At least such is the custom in this city.

The writer wishes, therefore, to bring to your attention the importance of having all of these connecting pipes extended from the main pipes to the vacant lots at the time the main sewer and pipes are laid in the street. This, however, is often attended with difficulty, on account of uncertainty as to what may be the future subdivision of the lots. Generally this subdivision can be ascertained quite closely by an examination of the recorded plats and the frontage of the improved lots and the connections adjusted accordingly. Assuming that the essential underground pipe connections are sewer, water and gas, that the block or square contains a frontage of 300 ft., that the subdivision into lots averages 30 ft., and that only ten of these lots have been built upon, there will be ten vacant or unimproved lots and ten unused connections. Basing the estimate of cost of such connecting pipes on that in a street 60 ft. wide, I find the average costs of connections in this city are as follows: Sewer connection, 10 ft. deep, $12.00; gas connection pipe, 2½ ft. deep, $6.00, and water connection pipe, 2½ ft. deep, $6.00, each of the latter having the necessary stop cocks at the curb line, making a total of $24.00 for each lot. Assuming the rate of interest upon the outlay to be 4 per cent., 96 cents would be the annual expense on this cost.

It is also the experience of the writer that in the communities where these conveniences, such as sewer, water and gas exist, the growth and improvement is rapid, and in a short time all the abutting lots are improved and occupied. Under the laws governing the city of Richmond, the cost of water and gas mains, as well as connections to same, are not charged to the abutting property, nor is the main sewer, but there is an annual sewer tax of ten cents for every foot of frontage in the street, and the cost of the sewer connection is paid by the lot owner only where the fixtures on the lot are connected, and the owner of the vacant lot does not pay for this connection to the sewer until it is used. The increased value of the abutting property, however, is so great, because of having the necessities and conveniences of sewer, gas and water, that the tax receipts are greatly in excess of the small annual interest on the cost of pipe connections. It is evident that this cost for pipe connections is warranted. In all cases where the street has already been paved or otherwise improved, the cost of making the pipe connection is at least 60 per cent. greater than in the unimproved street, and the restoration and maintenance of the paving of the street, in the end, amounts to double the original cost. Again, had these different pipes and pipe connections been constructed prior to paving the street surface, the opportunity would have been afforded for carefully treating the trenches and fills and thoroughly and properly preparing a road base.

The writer recognizes the fact that the time will never come when the streets of a city or town will not have to be cut into for repairs and various other purposes, and that to a large extent what he has brought to your attention applies to local conditions, as evidenced in his own long experience. But at the same time he feels assured that by consideration, co-operation and the construction of underground pipes prior to the surface improvement of a road or street, much money can be saved in construction, and especially in the maintenance, of both roads and streets.

This paper is intended only to apply to underground pipes used in municipal service and not to pipes for road drainage, which properly belongs to road construction.

* Paper presented before Section D of the American Association for the Advancement of Science at the annual meeting at Washington, D.C., Dec. 26-29, 1911.

The Canadian Engineer

ESTABLISHED 1893.

ISSUED WEEKLY, in the interests of the CIVIL, MECHANICAL, STRUCTURAL, ELECTRICAL, MARINE AND MINING ENGINEER, THE SURVEYOR, THE MANUFACTURER, AND THE CONTRACTOR.

Managing Director: JAMES J. SALMOND.
Managing Editor: T. H. HOGG, B.A.Sc.
Advertising Manager: A. E. JENNINGS.

Present Terms of Subscription, payable in advance

Postpaid to any address in the Postal Union:

One Year	Six Months	Three Months
$3.00 (12s.)	**$1.75** (7s.)	**$1.00** (4s.)

Copies Antedating This Issue by More Than One Month, **25** Cents Each.
Copies Antedating This Issue by More Than Six Months, **50** Cents Each.

ADVERTISING RATES ON APPLICATION.

HEAD OFFICE: 62 Church Street, and Court Street, Toronto, Ont. Telephone Main **7404** and **7405**, branch exchange connecting all departments.

Montreal Office: B33, Board of Trade Building. T. C Allum, Editorial Representative, Phone M. 1001.

Winnipeg Office: Room 404, Builders' Exchange Building. Phone M. 7550. G. W.. Goodall, Business and Editorial Representative.

London Office: Grand Trunk Building, Cockspur Street, Trafalgar Square T. R. Clougher, Business and Editorial Representative. Telephone 527 Central.

Address all communications to the Compan and not to individuals. Everything affecting the editorial department should be directed to the Editor.

The Canadian Engineer absorbed The Canadian Cement and Concrete Review in 1910.

NOTICE TO ADVERTISERS.

Change of advertisement copy should reach the Head Office two weeks before the date of publication, except in cases where proofs are to be submitted, for which the necessary extra time should be allowed.

ENGINEERING ETHICS.

Too often we read in the papers that certain works for municipal corporations are inadequate in some respects for the part to be performed. Insufficient funds have been provided for thorough and efficient design, and as a result some part or parts, or even the whole, has had to suffer. The engineer is quick to criticize the city council when poor results are obtained by stating that he was handicapped through lack of sufficient money. In many cases this is true, but we must not lose sight of the engineer's initial responsibility in accepting the work with the knowledge of the facts.

In a recent investigation into the filtration plant of one of our large cities the consulting engineer for the work, in giving evidence before a court of inquiry, made the remark that in his opinion the city had obtained good value for the money expended. While this statement was true, it reflects little credit on the engineer. The point in the enquiry which appeared to be lost sight of was the fact that the sum voted for the completed plant was too small. The cost of the completed plant per million gallons of water treated is about two-thirds that of American plants under similar conditions. The reason for this low cost is plain from the facts brought out during the investigation. The pumping plant is too small, and compressed into a small building; little or no reinforcement was used for the concrete; lean-tos had to be erected to house part of the boiler plant.

The council and the Board of Control are blamed for this by reason of the small amount of money provided, and undoubtedly to this fact is due the above state of affairs. On the other hand, the consulting engineer, to be just to his client and to be fair to himself, should not take on work knowing that the sum appropriated for the design and construction is insufficient. It is his duty to inform his clients that he will not proceed with the design until sufficient money is provided for adequately covering the work.

If a bridge engineer were asked to design and construct a bridge to carry certain traffic for the sum of $10,000, and he knew it was impossible to erect such a bridge for any amount less than $15,000, which would be safe for the conditions specified, it would be criminal on his part to proceed with the work. Where the element of human life does not enter in such a large degree, as in this example, very often the engineer is inclined to overlook this aspect of his professional code of ethics.

ENGINEERING EDUCATION.

The subject of engineering education is one which has received a good deal of attention in the technical press. In a recent issue of the Engineering Magazine some reference was made to the present tendencies in the teaching of technical subjects and to the general problems arising in connection with engineering education.

Problems of engineering education are rapidly increasing in difficulty but the difficulties are perhaps not so apparent to the individual teacher presenting a single subject as to the faculty who must co-ordinate many subjects, or to the student who must within the period of the curriculum prepare himself for his special field of engineering work. Every one of these fields (civil, mechanical, electrical, mining, industrial) is rapidly expanding. New subjects are coming up; new specializations are evolving. To be prepared for whichever specialization may demand his life work, a student must make some preparation for all. The total weight of the

resultant work threatens to exceed the elastic limit of the time set for the course. The six-year course, supplanting the former four-year course, is already announced; and many able and earnest thinkers on the subject, looking back to the days when men began younger, and worked out their learning in parallel with their experience, fear serious disadvantages from the long residence in academic bounds and the late entry into the field.

Perhaps one difficulty comes from the conscientious thoroughness of the specialist teacher. He seeks the impossible purpose of turning out specialists. Perhaps another difficulty is the attempt to show too much practice. Practice cannot be efficiently reproduced in academic institutions whose function is rather to explain and inculcate principles—scientific data upon which practice is founded. Perhaps the greatest difficulty of all goes back to the preparatory schools. The university tries to build too intricate a structure upon too small a foundation, not always well laid, and, finding this insufficient, attempts to extend the foundation while construction is going on. The solution seems to lie in the direction of a much broader foundation and a much larger, more broadly conceived, but more elementary framed structure built upon it by the college course, leaving much of the arrangement and elaboration of the spaces between that framing to be completed after the student's more permanent intellectual leases have been let.

What we need most and increasingly is not more handicraftsmen, nor men skilled in more handicrafts, but more engineers of broad vision and wide general culture, capable of organizing and administering the work of the narrowly skilled, even if specially skilled, professional practitioner.

EDITORIAL COMMENT.

The article in this issue on the Zinn Building by Mr. T. Kennard Thomson will be of considerable interest to all engineers having to do with pneumatic caisson work. Mr. Thomson is one of the greatest living authorities on this question, and the methods used on this work are exceptional.

* * * *

A member of the Board of Control of Winnipeg objected recently to the cost of inspection. He said that the erection of city buildings was costing a great deal more than it should on account of the number of inspectors employed. This is a very good fault, indeed, if the system of inspection is efficient.

* * * *

It was announced last week by the Ontario Provincial Legislature that another million dollars is to be devoted to continue contributions toward the cost of good roads built by counties under the Highway Improvement Act. The previous million dollar grant for this purpose took ten years to dispose of. We venture to say that this million will last less than half that time.

* * * *

The recommendations of the Conservation Commission and the warnings of practical lumbermen will soon force the hands of the Dominion Government in connection with the present forestry policy. It is likely that steps will soon be taken to extend the present fire ranging system. While the protection question is important and demands immediate action, the reforestration of our burned lands and the planting of our waste places is of equal importance.

THE ANNUAL MEETING, ASSOCIATION OF ONTARIO LAND SURVEYORS, TORONTO, FEB. 27th, 28th, 29th.

The twentieth annual meeting of the Association of Ontario Land Surveyors will be held at Toronto, February 27th, 28th and 29th in the lecture-room of the Engineers' Club, 96 King Street West. As the members of the Association are honorary members of the Good Roads Convention, those coming by rail will be granted a reduction of fares upon presenting proper certificate. Blank forms for the certificates must be procured from the local railway agents when the single fare tickets to Toronto are purchased.

PROGRAMME.

Tuesday, 27th February.

Morning, 10 o'Clock.

Meeting of Council of Management.
Meeting of Standing and Special Committees.

Afternoon, 2 o'Clock.

Reading of Minutes of previous meeting.
Correspondence.
President's Address—J. F. Whitson.
Report of Council of Management.
Report of Secretary-treaurer (including Financial Statement).
Report of Board of Examiners.
Report of Committee on Legislation—G. B. Kirkpatrick, Chairman.
Report of Committee on Publication—Killaly Gamble, Chairman.
Report of Committee on Topographical Survey—Thos. Fawcett, Chairman.
Report of Committee on Exploration—H. T. Routly, Chairman.
Paper—"Rights of Way"—D. D. James.

Evening, 8 o'Clock.

Report of Committee on Repository and Biography—H. L. Esten, Chairman.
Report of Committee on Polar Research—Willis Chipman, Chairman.
Paper—"Canada's Mineral Wealth"—Dr. W. G. Miller.
Paper—"A Trip to Hudson Bay in 1900"—L. V. Rorke.

Wednesday, 28th February.

Morning, 10 o'Clock.

Report of Committee on Engineering—James Hutcheon, Chairman.
Paper—"Coal Tar for Roads"—James Hutcheon.
Paper—"Underground Surveys"—R. W. DeMorest.
Paper—"A Mountain Railway in Norway"—C. C. James, C.M.G.
Report of Committee on Drainage—George Ross, Chairman.
Paper—"Conservation in Canada"—James White.
Paper—"What Land Surveyors can do to Promote the Settlement of our Agricultural Lands in New Ontario"—J. F. Whitson.

Afternoon, 2 o'Clock.

Report of Committee on Land Surveying—J. McC Watson, Chairman.
Paper—"City Surveying"—T. B. Speight.

Paper—"Town Planning"—W. J. Moore.
Paper—"Re-marking of Governing Lines by the Government"—C. F. Aylesworth.
Report of Auditors—J. H. Burd and N. A. Burwash.

Evening, 7.30 o'Clock.

Dinner at McConkey's Restaurant.

Thursday, 29th February.

Morning, 10 o'Clock.

Report of Committee on Entertainment—A. T. Ward, Chairman.
Nomination of Officers:—President, Vice-President, Secretary-treasurer, two Members of Council, Auditors.
Unfinished Business—New Business—Adjournment.

ANNUAL MEETING ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION, TORONTO, FEBRUARY 26th, 27th, 28th.

PROGRAMME.

Monday, February 26th—Morning Session, 10 a.m.

Report of Executive; Appointment of Committees.
President's address—Major T. L. Kennedy, Dixie.
Address—W. R. Cummings, Cummings' Bridge.

Afternoon Session, 2 p.m.

Address—R. G. Geary, Mayor of Toronto.
Address—Andrew Broder, M.P., Morrisburg.
Address—Geo. S. Henry, Oriole.
Federal Aid for Highway Improvement—H. J. Bowman, Berlin.
County Road Construction, Ontario (illustrated)—W. A. McLean, Provincial Engineer of Highways.

Tuesday, February 27th—Morning Session, 10 a.m.

Address—Hon. J. O. Reaume, Minister of Public Works.
Address—W. G. Trethewey, Toronto.
State Highway Systems—Hon. Paul D. Sargent, Assistant-Director United States Office of Public Roads, Washingon, D.C.

Afternoon Session, 2 p.m.

Address—E. B. Osler, M.P., Toronto.
Address—A. M. Rankin, M.P.P., Collins' Bay.
Foreign Road Systems—L. A. Hamilton, Lorne Park.
Bridge Construction—James A. Bell, C.E., St. Thomas.

Wednesday, February 28th—Morning Session, 10 a.m.

In Reception Room, Parliament Buildings.
Report of Committee on Resolutions. Discussion.

11 o'clock.

Deputation to the Provincial Government. Speakers:—Mayor Hopewell, Ottawa; L. A. Hamilton, Lorne Park; E. M. Young, Picton; S. L. Squire, Waterford.

Afternoon Session, 2 p.m.

Address—James Armitage, Dunrobin P.O.
Township Roads—J. P. Griffin, Nelson; W. C. Bush, Port Dalhousie.
Election of officers.

GENERAL NOTES.

Precipitation exceeded the average in Central British Columbia and Alberta, also in the Highlands of Ontario, and very generally throughout Quebec and Eastern Nova Scotia; elsewhere in Canada it was deficient and to a pronounced extent in Saskatchewan and Manitoba. Although no definite depths of snow on the ground have been reported from British Columbia, it appears that there is a light covering near the Coast, and a considerable amount in the interior with excellent sleighing. In Keewatin the snow covering exceeds 20 inches, but in the Western Provinces, generally, the depth is from 2 to 8 inches. Twenty to thirty inches of snow covers the ground in the Highlands of Ontario and a lesser quantity, varying with the district, in other parts of the Province. In Quebec a depth of 13 inches at Montreal increases to 60 inches over the Gaspé Peninsula, while in the Maritime Provinces the snow is about 2 feet deep in Northern New Brunswick, and the depth decreases to about half inch in South-western Nova Scotia, although Cape Breton Island is covered with about 30 inches.

The table shows for fifteen stations, included in the report of the Meteorological Office, Toronto, the total precipitation of these stations for January, 1912:—

	Depth in inches	Departure from the average of twenty years
Calgary, Alta	0.6	+0.14
Edmonton, Alta.	1.1	+0.39
Swift Current, Sask.	0.4	—0.26
Winnipeg, Man.	0.3	—0.67
Port Stanley, Ont.	3.3	—0.03
Toronto, Ont.	2.97	+0.16
Parry Sound, Ont.	7.3	+2.84
Ottawa, Ont.	3.0	+0.01
Kingston, Ont.	2.5	—0.37
Montreal, Que.	2.9	—0.85
Quebec, Que.	3.9	+0.70
Chatham, N.B.	3.1	—0.48
Halifax, N.S.	6.0	+0.15
Victoria, B.C.	4.1	—0 44
Kamloops, B.C.	1.2	+0.25

BUFFALO CITY WATER.

During the year 1911 the Department of Health of Buffalo, N.Y., had almost daily tests made of samples of water from the new and old tunnels by which the city draws its water supply from Lake Erie. Comparing the results, they found no decided difference from a bacterial standpoint in the quality of the water taken through the two tunnels, one of which takes the water from the lake proper and the other from the harbor. On days when weather conditions are such as to affect only the water of Lake Erie the tests are relatively the same. When the wind storms increase the amount of water at the end of the lake, raising the elevation in Buffalo's harbor, the tests show the water from the new tunnel to be superior to that from the old. During November colon bacilli were present in 1 cc. samples taken from the new tunnel seven times and eleven times in samples taken from the old tunnel. It is found to be a normal condition that there is a large amount of sedimented silt and organic matter in the water supply, and in view of this and the bacterial conditions some method of purifying is recommended.

THE PRINCIPLES OF SPECIFICATION AND AGREEMENT WRITING.

By C. R. Young, A.M. Can. Soc. C.E.

(Registered in accordance with the Copyright Act.)

Second Article.

THE COMPOSITION OF AN ENGINEERING CONTRACT.—Continued.

Relation of Specifications to Plans.

The great assistance which graphical representations furnish to the intellect leads to the making of plans or sketches as the initial step in the maturing of a constructional project. Errors and impracticable features are detected in this way much more readily than in written descriptions, and information which could be imparted only in paragraphs of writing is by graphical means conveyed at a glance. There are always certain facts, however, which may be expressed as well, and sometimes only, by means of writing, and, in order to avoid a great number of notes on the plans, these are set down in specifications. The specifications are thus complementary to the plans; they do not replace them, but contain information which it is not practicable to give on the plans. Generally, the specifications are prepared after the plans are complete, or when they are well under way, and, therefore, in case of conflict, it is reasonable to give the specifications precedence. Information which is last prepared is more likely to be correct than that prepared at an earlier date. Since errors discovered in preparing the specifications are often left uncorreted in the plans, it is desirable to not duplicate information on the plans and specifications.

Relation of Agreement to Specifications.

Specifications are intended to serve as an accurate guide in the actual physical construction, erection and finishing of the work, and sometimes also as a code of rules for the preparation of designs. In them should be set forth all the requirements of the Owner respecting the extent of the work, quality of the materials and workmanship, the tests to which the construction may be subjected, and analogous matters. To facilitate constructional operations, and to obviate disputes and delays, certain "General Clauses" are also inserted defining the authority and procedure of the Contractor and the engineer, or their representatives, on the work.

The agreement, on the other hand, records the mutual assent of the contracting parties to a proposal involving the performance of some act by one of the parties in return for some consideration from the other. The nature of this consideration and the general business relationship to be maintained between the parties during the progress of the work should be clearly stated. Whatever the form, extent or detailed construction of the agreement may be, it should, above all else, clearly and unequivocally disclose the mutual intention of the parties in signing the contract. This portion of the contract is thus of a more distinctively business or legal character than the specifications, although, as has already been pointed out, the latter are, quite as much as the agreement, a part of the contract.

Practice differs somewhat as to the relative length of the agreement and the specifications. Some engineers and architects place most of the so-called "General Clauses" or "Conditions of Contract" in the specifications, and thus keep the agreement very short. The advantages claimed for this method are that a standard form of agreement can thus be made to serve for a variety of contracts, and that a considerable number of changes may be made without affecting the agreement or the formal or "legal" part of the contract. On the other hand, many prefer to incorporate the "Conditions of Contract" in the agreement, or attach them to this part of the contract, leaving to the specifications only the description of the actual physical characteristics of the work. Legally, it is immaterial whether the general clauses are placed in the specifications or in the agreement, as a change in a clause affects the contract quite as much if the clause is in the specifications as if it were in the agreement. The writer is of the opinion that, on the whole, it is preferable to confine matters of the general business relations, privileges and responsibilities to the agreement, or to the **general** part of the contract—the part which the owner or any layman could most readily understand. The specification then becomes a brief technical document, containing in it all that most of those having to do with the actual physical construction of the work will require to consult.

Should any disagreement be discovered between the provisions of the specifications and the agreement, the latter is generally given precedence, unless the evident intention of the parties as disclosed in the contract as a whole would lead to a contrary interpretation. This arises from the fact that the drawing up of the agreement is the final step in the preparation of the contract, and because the contracting parties themselves are likely to inform themselves concerning the contents of this portion of the contract. The specifications are of necessity prepared by a technically-trained adviser of the Owner, and seldom, if ever, would the Owner or other lay party to the contract read them over. On the other hand, the agreement deals with matters familiar to all, and, since it contains the formal binding promise of the parties, they are likely to look it over carefully before affixing their signatures.

LEGAL ESSENTIALS OF A CONTRACT.

The Four Legal Essentials.

A contract is a promise, enforceable by law, to do, or to refrain from doing, some act. In order that it may be capable of enforcement it must conform to certain legal requirements based upon the English common law, and which have been elucidated and confirmed by a vast number of decisions in the courts of the English-speaking world. These essentials, without all of which no contract is binding, are, according to Wait, Johnson, and other authorities, as follows:—

1. The two contracting parties must be **competent** to enter into a contract.
2. The subject-matter of the contract must be **lawful.**
3. There must have been a **mutual assent** or agreement to the conditions named, or the two parties must have been of the same mind or intention regarding the subject-matter.
4. There must have been a valuable **consideration**; that is, something given in exchange for its legal equivalent.

The four essentials may be described briefly by the words, **Competency, Legality, Mutuality,** and **Consideration,** and under these headings the legal requirements of contracts will be discussed, with particular reference, of course, to those relating to engineering work.

Competency.—The right to enter into binding contracts is not universal, but is limited by law to those

persons, or groups of persons, who are physically and mentally capable of responsbility; and whose authority or powers in the matter under consideration are not specifically restricted by statute.

Among individuals, imbeciles, insane persons, convicts and confirmed inebriates are debarred from entering into binding contracts. Special care should be taken to avoid entering into an agreement with a man who is intoxicated, as he may, if the arrangement does not turn out to his satisfaction, be able to effect a release from it on the ground of irresponsibility. Persons under twenty-one years of age, and legally termed infants, may escape from the provisions of a contract if they so desire. Agents, as for example, engineers or architects, are not able to enter into contracts in the name of their principals concerning matters other than those over which they have been given authority. If the agent can be shown to have an interest in the affairs of the party which is contracting with his principal, the contract is voidable.

Groups of persons or organizations have certain contractual powers if they are incorporated. Thus, a private corporation may enter upon, and make contracts relating to any activity permitted by its charter, or any venture which, while not expressly mentioned in the charter, may be regarded as necessary for the complete carrying out of its specific purposes. On the other hand, congregations, societies, clubs, associations, or any unincorporated bodies cannot enter into binding contracts since they have no legal existence. In such cases it is necessary to have certain individuals personally pledge themselves for the amount involved if the other party to the contract is to effectually safeguard himself against loss.

Governments and governmental commissions may enter into contracts in much the same manner as individuals, but the powers of municipal corporations are restricted by law to those conferred upon them by Parliament or established by their own by-laws. It is of interest to contractors to note that, while suits may be brought against a municipal corporation, the Provincial and Dominion Governments may not be sued without their consent.

Legality.—In order that the subject-matter of a contract may be legal it must not transgress any statute, must not be opposed to the accepted principles of ordinary justice, or the common law, as it is called, nor opposed to public policy.

Violations of statutory law are involved in such contracts as the following: Contracts relating to the payment of a fee to an unlicensed practitioner (a surveyor, for example); contracts for undertakings beyond the legal powers of either of the contracting parties, as municipal work, the payment for which would require the statutory debt of the municipality to be exceeded; contracts let without the amount of advertising required by law; or, in some municipalities, contracts let to a bidder other than the lowest.

A contract is opposed to the common law, and is, therefore, illegal, which is based upon any fraudulent transaction or act. Changes in contracts made by one of the parties without the consent of the other, or by both without the conent of the sureties, render it void.

There are certain provisions commonly occurring in engineering contracts which, if enforced, would be prejudicial to the public welfare, and which render the contract illegal in so far as these clauses are concerned. For example, although parties are allowed to settle disputes by arbitration, either party may refuse to be bound by the award and carry his case to the courts. The law will not allow anyone to bargain away his right to be heard in a court of justice. Also, although agreements may be signed calling for the exaction of a penalty from one of the parties on failing to carry out his promise, this provision cannot be enforced unless the amount specified was intended to be a "genuine pre-estimate of damages" and not an arbitrary penalty. The right to inflict penalties is the prerogative of the law and not of private individuals or organizations.

Mutuality.—A contract to be binding on both parties must have been understood and agreed to by the two parties in the very same sense. The character of this understanding is judged from the written contract itself, and if the wording dicloses any essential difference of intention between the two parties the document is illegal. Where no such difference appears, it is to be presumed that the parties were of the same mind with respect to the subject-matter. Neither of the parties can in general upset the contract on the ground that the wording does not express his intention, for it was his duty to see that a wording was adopted which did express his understanding of the proposition. The exception to this is where one party has been misled or misinformed by the other, or by some one interested in the other, and has entered into the agreement with an erroneous conception of the actual facts. If the objectionable character of the contract is thus due to the fault or negligence of the complainant, he has no redress, but if it arises from the fault of some one interested in the other side he can have the contract set aside.

Consideration.—Unless the contract is under seal, there must be a valuable consideration, transferred from each party to the other. This does not require to be money, but may be anything whatever of value; for example, some work or act, or, indeed, the forbearance to do some act which the party transferring has a legal right to perform. The question of adequacy of consideration is, in general, not examined into by the courts, since it is presumed that the parties making the bargain should be the best judges of the worth of the consideration to them. If, however, the consideration is grossly inadequate or absurd, the courts will refuse to enforce the contract.

DESIRABLE CHARACTERISTICS OF AN ENGINEERING CONTRACT.

While a contract may possess all the legal essentials, it may, nevertheless, be very far from the ideal. Ability to successfully withstand attempts to upset it is not the only test of excellence. If, as a result of unfairness, ambiguity or other defects, disputes and litigation follow, it is undoubtedly a very badly-prepared contract. There are, therefore, many desirable characteritics of engineering contracts other than the formal legal requirements, and of these the following are among the most important:—

(1) Fairness.
(2) Completeness.
(3) Accuracy.
(4) Clearness.
(5) Brevity.
(6) Convenient arrangement.

Fairness.—The lack of fairness in an engineering contract may result in great hardship to a Contractor through no fault of his. Those who do not care to render themselves liable to unreasonable exactions will not bid on work under such auspices, and the Owner secures only a limited competition. If a reliable Contractor does bid, he covers himself by adding a considerable amount to offset the probable effect of the enforcement of the unfair

clauses in the contract. The reckless Contractor takes a gambler's chance in the hope that the untoward circumstance will not develop, and if they do, he does his best to extricate himself by influences of a more or less questionable character.

Unfairness in a contract may be exhibited in a great variety of ways. It is unfair, and generally unprofessional, for an engineer to require a Contractor to guarantee the engineer's plans. The engineer who takes such a position does not possess sufficient confidence in himself to be an engineer. Scarcely more defensible is the practice of the engineer disclaiming all responsibility for the quantities set down in the specifications or in the notice to bidders. In the short time generally allowed the Contractor for the preparation of his bid it is often impracticable for him to make explorations and calculations with anything like the thoroughness and accuracy which have presumably characterized the investigations of the engineer. If the Contractor were able to, and did, expend the time and money necessary for this preliminary work, the Owner would have to pay twice for such services. The engineer should accept the responsibility for his own quantities in so far as they are capable of accurate determination. Unfair, also, is the provision that the Contractor shall assume all risks of whatever kind. It is only right that he should be responsible for his own operations and for the acts and negligence of his own workmen, but to require him to assume responsibility for accidents arising from no fault of his own is unjust. Another instance of unfairness is the practice of specifying that the Owner will settle claims for damages and charge the amount up to the Contractor. The latter should be allowed to defend such actions himself in his own way, since the Owner cannot be expected to throw much energy into defending suits which, financially, are no concern of his.

Fairness to the Contractor, and at the same time the best interests of the Owner, require that the engineer should do all in his power to assist the Contractor to prepare an accurate, well-balanced bid. Anything new or unusual in construction, any detail differing in important particulars from those in similar work previously executed by the Contractor, or any changed clauses in an otherwise familiar specification, should be carefully pointed out to him before the submission of his tender. It never pays an Owner to award a contract at less than a fair price, for the Contractor will proceed to clear himself as best he may by inferior workmanship and by supplying poor materials.

Completeness.—The elimination of recklessness in bidding on the one hand, and inordinately high tenders on the other, necessitate completeness and definiteness throughout the contract. All information concerning the extent, general character and details of the work which would in any way affect his bid should be furnished the Contractor. A typical incomplete provision, calculated to provoke a dispute later on, would be the requirement that a surface is to be "plastered with cement mortar" without mention of the mixture or the thickness of the coat. Definite rules for the judging of the character of work and material should be laid down in the specifications. No clauses are more conducive to trouble and delays than those requiring the work to be "proper and sufficient," or "to the satisfaction of the engineer," or "as the engineer may direct." The bidder does not know just what the engineer may consider "proper and sufficient," and if his guess at the degree of severity likely to be maintained by the engineer in his rulings is not correct, the bid may be very wide of the mark. Provisions which are only half definite are likewise worse than valueless, since they lead to disagreements. For example, it is absurd to specify that "concrete shall not be dropped from a height," or "stones shall be as nearly cubical as possible." Such rules as are given should be absolutely definite and capable of but one interpretation.

In addition to the establishment of definite standards for judging materials and workmanship, completeness in the contract requires that all contingencies likely to arise in connection with the work and to materially affect it should be covered. It is not necessary that these probabilities should be the subject of lengthy provisions, but neither the Owner nor the Contractor should be continually confronted by matters which, because of undue brevity, were omitted in the contract. A few extra paragraphs in a specification may later on be the means of saving a great deal of time and a lawsuit as well.

Accuracy.—Unless a contract is accurate, or the limits of its accuracy is clearly defined, it is likely to entail trouble, and perhaps hardship, to one or other of the parties. Misleading quantities, as of earthwork, may cause a Contractor to submit a highly erroneous bid. The methods which would be suitable in removing a certain quantity of rock, and the price per cubic yard for which it could be handled, might be altogether inapplicable to half or twice that quantity. If the engineer cannot give exact quantities, the limit of variation at the prices named should be specified. If this limit were fixed for each kind of material at, say, 25 per cent., either way, and all work outside these limits were done on the "cost-plus-a-percentage" basis, the Contractor would know the worst at the outset, and neither party would be the subject of injustice. Not only errors in quantities, but errors in description of any kind are a serious obstacle to smoothness and despatch in the work, if, indeed, they do not precipitate litigation, or even void the contract.

Clearness.—Since the intention of the parties is, as expressed by Wait, "the pole star" in the interpretation of the contract, great care should be taken to express in writing precisely what was intended by both parties. Clearness is thus of paramount importance in the drawing up of contracts, and any device by which it is promoted is to be welcomed. While ambiguity may not result in voiding the contract, it may cause serious disputes, with attendant loss of time and money.

Brevity.—In general, the shorter the contract the better. The mastery of a document of a few pages is a much easier matter than the full comprehension of one of twice that length. Sometimes, also, the attempt to cover the work by mentioning everything in detail actually weakens the contract. Thus, where the joints between old and new concrete in an open-spandrel arch are required to be "at right angles to the dead load line of pressures in the ribs and at right angles to beams and slabs at their middle points," the provision does not apply to joints in spandrel posts. If the provision were that the joints were to be "at right angles to the line of resultant axial pressure and at the middle points of beams and slabs," it would be briefer and of more general application. However, contracts do not generally err on the side of undue length, and the plea for brevity cannot be regarded as of especial importance.

Convenient Arrangement.—The orderly statement of the facts forming the subject-matter of a contract is greatly to be desired. Not only does it save the time of those who have to consult the completed document, but it diminishes the probability of anything being overlooked in its preparation and interpretation.

POWER PLANT OF McGILL UNIVERSITY.

A paper by Mr. R. J. Durley on "The Central Heating and Power Plant of McGill University, Montreal," read before the Institution of Civil Engineers, described the arrangement and equipment of a central heating plant, combined with an electric light and power station, which was designed to serve the various buildings of the University.

Although only of moderate size, the installation, he said, was of interest on account of the somewhat severe climatic conditions and the unusual nature of the service. The climatic conditions were shown in a table which gave the maximum and minimum temperatures for the winter of 1908-9. These were, in deg. F.:—October, 1908, 74.6, 29.3; November, 56.3, 17.4; December, 52.1, —9.5; January, 1909, 42.3, —17.2; February, 41.2, —12.4; March, 41.8, 3.6; April, 67.0, 19.4, and May, 73.6, 33.5. Attention was directed to the fact that the economic possibilities of such a station depended very largely on the relation between the demand for heat and that for electric current.

Up to 1908 the University buildings were heated individually by their own steam or hot water equipment, and current was taken from the local electric supply company. The coal used for the heating service was necessarily of an expensive kind, and the cost of current was rather high, Economy and improvement in service, therefore, were sought by utilizing cheaper coal in a central boiler plant and by heating the various buildings from one source, employing for this purpose as far as possible the exhause steam from electric generating sets. The buildings which would ultimately be served had a total volume of about 7,570,000 cu. ft.; they contained 81,000 sq. ft. of direct-radiation heating surface, needed 185,000 cu. ft. of warmed air a minute for ventilation, and required a maximum of about 475 kw. for light and power. The greatest demand for steam for heating and ventilation for all the buildings in cold weather would be about 30,000 lb. an hour. The station as at present working supplied current to 11 buildings and heat to five. The heating service would be extended to all the buildings as opportunity served.

A brief discussion of the systems of heating and ventilation in general use in Canada for large buildings and a description of the nature of the demand for steam and current for the University purposes was followed by notes regarding some of the problems arising in the design and construction of underground piping systems for steam and hot water. The McGill power-house itself was not of an unusual type, its equipment including four water-tube boilers, three steam electric generating sets, the necessary heaters and auxiliary machinery, and the ordinary apparatus for the switchboard and electric accessories. The heat distribution to the buildings being largely by means of forced-circulation hot water as well as by steam, the heaters and circulating pumps were installed in the engine-room, and were at present capable of supplying hot water to 60,000 sq. ft. of direct-radiation heating surface. Means were provided for obtaining a record of the heat delivered to the heating surface. Means were provided for obtaining a record of the heat delivered to the heating systems of the various buildings.

The electric distribution was effected by underground cables throughout, the cables as well as the heat distributing pipes being carried partly in tunnel and partly in conduit. Secondary heaters had been installed in two of the buildings in order to avoid the expense of renewing the existing heating pipes and radiators. The paper concluded with a description of the methods of operation adopted and the systems of temperature regulation employed, together with some notes as to working costs.

LIGNITE IN SASKATCHEWAN.

Mr. Geo. Bell, M.P.P., of Estevan, Sask., has introduced a bill before the Provincial House calling for an enquiry into the immense deposits of lignite throughout the province. In introducing the bill Mr. Bell said there were enormous deposits of coal in the province; the quantity was practically unlimited. The coal was of peculiar character. The quality is lignite, and not of the best. It contains the smallest percentage of fixed carbon, and is therefore small in heat value. His object in bringing up the resolution was to secure full information regarding the feasibility of using the coal for power or other purposes. Because of the great quantity of moisture in the coal it was as yet of very little use in its raw state. By pulverizing the coal and allowing the entrance of considerable air, the coal was found fairly satisfactory for furnace use. It is possible that some further development along that line might be effected by the inquiry proposed. It was found in the United States that lignite coal could be used successfully for gas producer purposes. Similar experiments with more or less satisfactory results had been made in Germany and England. The most interesting experiments were made recently by the mines branch of the Univserity of North Dakota. The coal was very similar, containing practically one-third moisture and one-third carbon. Experiments made with the raw coal had proved to be a failure, and it was impossible to make briquettes. The North Dakota experiments, however, used the coal after being roasted in a retort. The residue was mixed with a satisfactory binder, and a briquette formed which would withstand exposure to the elements, and which possessed a very high heat value. They burned without disintegrating, and were entirely consumed. The ashes were found to contain less unconsumed carbon than anthracite ashes. The result was that the briquettes were found to be equal to twelve-thirteenths of a similar quantity of anthracite coal. The same fuel was believed to be very satisfactory for producing gas. No figures were given, however, as to the probable cost of producing power from this source, and as Saskatchewan possessed no figures as to the cost of transmission the inquiry should provide a great deal of useful information. The possibility of securing from the coal deposits a high-class domestic fuel opened up a very important avenue of development.

This lignite coal will not stand transportation. It will not hold together when exposed to the air. This fact results in the coal mines being idle for about half the year and the consequent tying up of that amount of capital for a greater part of the year. The freight on the coal is just as high as on better classes of fuel, and the result is a very serious handicap to the coal mining industry.

There is a possibility of finding a cheap source of power, for each ton of coal produces 11,000 feet of gas.

HUDSON BAY WORK.

The Dominion Government has decided to send engineers to examine Port Nelson and Fort Churchill, on Hudson Bay, and report as to which will make the most suitable terminal for the line from Le Pas. The engineers will leave for Winnipeg in the course of a few days, and will there take dog train for Hudson Bay. The Government hopes to have a report early in the year, so that further contracts can be let.

MUNICIPAL WATER PURIFICATION PLANT, GRAND RAPIDS, MICH.*

By J. W. Armstrong, C.E.

The filtration plant now being constructed for the City of Grand Rapids is the outgrowth of a project which was first seriously undertaken some twelve years ago. Little real progress was made, however, until 1909, when Messrs. Hering & Fuller were employed to report upon the best available method of securing a new water supply for the city. They advised in February, 1910, the construction of a mechanical filter plant having a capacity of twenty million gallons daily. for purifying the water of the Grand River, and that a complete water-softening plant, together with all the necessary appurtenances, including reaction and coagulating reservoirs, be built for preparing the water for filtration. A clear-water reservoir of three million gallons capacity was also recommended.

The water of the Grand River is a moderately hard water for the central West, and a very hard water, as viewed from the standpoint of waters of the Atlantic seaboard. It is about twice as hard as the water of Lake Michigan. It is frequently uninviting in appearance, partly due to the color or vegetable stain which it contains, and this is augmented at times by soil wash, which produces more or less turbidity or mud in the water as supplied to the consumers. As regards the bacterial analysis, the water, while polluted to an extent that makes it undesirable and at times unsafe for drinking purposes in its raw condition, is certainly not grossly polluted, and can be made entirely satisfactory in quality after being treated in a thoroughly well built and well operated filtration plant.

A brief description of the course taken by the water in its passage through the plant may prove helpful in understanding what follows:

The water passes from the intake into a concrete conduit to the pumping station, where it is picked up by a centrifugal pump and forced into an equalizing chamber in the head house. From here at times of high turbidity in the river, it enters into the grit chamber, where sand and heavy suspended matter is settled out. After passing through the grit chamber it enters a mixing chamber, where the chemicals are applied, and the water is kept in rapid motion until the proper reactions have taken place, when it is admitted into the coagulation reservoirs, where the water is prepared for the filters and most of the impurities are precipitated to the bottom. After leaving the coagulating reservoirs the water passes through the sand filters, and from there into the clear-water reservoir, from which it is finally led through a concrete conduit to the high-lift pumping station.

The pumping station is located centrally and adjacent to the filter gallery. The centrifugal pumps, which are of the single-suction vertical-shaft type, are located in a pit. The pumps are placed with their centres below extreme low water level in the river, which insures their being always primed. There are three raw-water pumps, each capable of lifting eight million gallons a day against a head of thirty feet. There are two smaller raw-water pumps, each of a capacity of four million gallons a day against the same head. On a tee in the suction line of one of these pumps a valve is attached which opens into the room and is operated by an extension stem from the floor above. This enables the raw-water pump to be used as a sump pump should the pit become flooded. The raw-water pumps are designed to be operated automatically, starting when the water falls below a certain level in the epualizing reservoir and stopping when it reaches a certain predetermined elevation. They are also capable of being operated by hand. All the raw water is discharged into a 36-inch force main laid under the floor of the filter gallery, in which is placed a 36-inch Venturi meter with an 18-inch throat. This arrangement effected quite a saving in the length of piping, but prevented an ideal arrangement of the pipe gallery.

The two wash water pumps each have a capacity of 1,000 gallons per minute against a maximum head of 52 feet. These pumps discharge their water into the wash water main in the centre of the filter gallery. They are designed to stop automatically when the water reaches a certain elevation in the wash water tower, but they require to be started by hand. The reason for this method of operation is to enable the exact amount of water required for each filter washing to be accurately determined, which could not be done if water were to be pumped into the tank at the same time it was being withdrawn. The motors operating the pumps are located upon the ground floor, and they will be run by alternating current of 440 volts, transmitted through underground cables from the high-lift pumping station.

The water is pumped into an equalizing chamber in the head house, which acts as a centre of distribution, and from there it ordinarily passes directly into the grit chamber, through a 42-inch by 42-inch sluice gate. During flood times the river water contains a great deal of sediment that is extremely desirable to get rid of before applying the chemicals. Most of the heavier suspended articles will be deposited by plain subsidence in traversing the grit chamber, which is 152 feet 8 inches long and 21 feet wide, and will hold about 367,000 gallons.

The mixing chamber is adjacent to the grit chamber and is 44 feet wide by 160 feet long and holds approximately 732,000 gallons. Wooden baffles of the "around-the-end" type are spaced three feet apart for the full length of this chamber. This type of baffle permits the operation of the plant with varying heads of water and offers reasonably good facilities for cleaning and inspection. Water can be drawn from the mixing chamber at four different points through the sluice gates. As the condition of the water changes, the time for chemical reaction can be shortened and lengthened. Should the water be drawn from the gate most remote from the entrance it will have to travel four times as far as it would if drawn out at the first gate and the time for chemical reaction would be correspondingly lengthened. The grit chamber and mixing chamber were designed with flat top and bottom, the bottom being reinforced in the style of a mushroom floor system for the purpose of resisting upward pressure.

There are two coagulating basins. The smaller of the two basins is 88 feet 6 inches by 118 feet 9 inches, and holds 1,134,000 gallons; the larger basin is 118 feet 6 inches by 118 feet 9 inches, and holds 1,452,000 gallons. The basins can be operated singly in parallel or in series. They are covered with groined arches supported by columns. It has been noticed in reservoirs with a few baffles that there is a tendency for water to short-circuit and for the floe to settle out unevenly in different parts of the reservoir. In order to overcome this difficulty and to maintain a more even distribution of the floe, the baffles in this basin are much closer than has been the case heretofore, being fifteen feet on centres. The water is withdrawn from the reservoirs over a skimming weir made of thin stop-planks. The object in using the thin planks is to interpose a weak point that would give way should the water suddenly be withdrawn on the opposite side, and thus save the concrete work, which is not designed to withstand a full water load. They offer the further advantage of enabling the water to be taken from various depths below the surface.

* From a paper before the American Society of Municipal Improvements.

A feature of this plant which has saved considerable piping and a number of valves, is the double conduit. The water from the mixing reservoir enters the lower compartment of this passage through one of four sluice gates and from there enters the coagulating basins through a sluice gate. After passing through the coagulating basins the water is taken into the upper compartment and conveyed on to the filters. By-passes consisting of sluice gates opening either into the upper or lower passage are so placed that the raw water may be cut out of the grit chamber and passed directly into the mixing chamber or directly into the coagulating basin, or all of the basins can be by-passed and raw water turned directly into the conduit leading on to the filters. Water that has been passed through the mixing chamber can also be admitted to the upper passage and taken directly to the filters, by-passing the coagulating basins. It is thus seen that an unusual degree of flexibility can be obtained in the operating of the plant.

There are ten filters with a normal rating of two million gallons each, five of which are on each side of an eighteen-foot pipe gallery. The filters are built of reinforced concrete, and are supported directly upon the groined arches which form the roof of the clear-water basin. They are 25 feet by 38 feet outside measurement. Each filter is divided into halves by a centre gutter, and there are twelve concrete lateral gutters, sixteen inches wide. In washing, all water is carried off through the lateral gutters, none of it being allowed to flow directly into the centre gutter. Each filter has about 738 square feet of sand area, aggregating 7,344 square feet for the ten filters.

The strainer system is constructed of concrete ridge blocks spaced in rows twelve inches apart across the filter. The end blocks are nine inches wide at the base and have perpendicular sides for a height of five inches, at which height a seat is left for the support of the perforated brass strainer plates, which extend in rows entirely across the filter. For a height of eight inches above the strainer plates the blocks are in the form of a truncated wedge. The space between the ridges is filled with four different sizes of gravel, held in place by a brass wire screen. The water, after passing through the filter sand and gravel, enters the water passage between the ridge blocks, from which it passes into the centre collector and from there into the pipe system underneath the filters. In washing the filters the direction of flow is reversed, filtered water being passed rapidly through in the opposite direction.

Filter rate controllers of the Earl type are to be installed. These controllers are constructed in such a way as to respond to the pumps. If the water level in the clear-water basin is lowered, the rate of filtration will increase until a maximum is reached when all filters will discharge at the maximum rate for which they are set until such time as the water again rises, when the filters will gradually slow down until the clear-water basin is full, and then shut down entirely.

As it would require very large pumps to supply the wash water at the high rate at which it is applied, it was decided to employ an elevated tank for washing the filters, which could be filled by means of small pumps during the interim between washes. This structure is built over the clear-water reservoir and the columns supporting it are carried to solid rock. The tank, supporting beams and columns, are built of reinforced concrete; the exterior is of brick to match the other buildings.

The main body of the head house is 46 feet by 60 feet 3 inches outside, which with the addition of a projection for the tower gives a total floor space of about 3,000 square feet. The building has a basement, ground floor, mixing floor and tower. The basement is divided into two parts, one of which receives the water from the pumps and acts as an equalizing chamber and distributing point for the raw water. The other compartment contains the steam boiler and coal storage bins, together with the elevating and crushing machinery, and a vacuum cleaner. Upon the ground floor are located the various operating stands for controlling the valves and sluice gates and all the chemical controllers. The operating floor contains all the apparatus for mixing and storing chemical solutions. The tower contains the bins for the storage of chemicals and the apparatus necessary for handling and conveying the material. The building is constructed of reinforced concrete with the exception of the outer walls, which are of brick.

From the solution tanks the chemicals will flow by gravity to the controllers which are located on the floor beneath, and after passing through the controllers will flow by gravity to the point of application to the water. The operator is enabled to vary the time allowed for chemical reaction to suit the changing condition of the water. For each of the solutions duplicate controllers of the Earl type are provided. They are all operated in conjunction with a Venturi meter and a master controller which so regulates the depth of solution that the head above the discharging orifice varies in direct proportion to the amount of water passing into the reservoirs through the meter. After the orifice has been properly set the action of the controller is entirely automatic, and however much the quantity of water passing through the system may fluctuate, chemicals in the correct proportion will be supplied. An additional alum controller is provided for furnishing the amount that may become necessary for corrective treatment. Each of the chemical solution tanks is provided with a recording gauge, operated by a glass float. The recording device is to be enclosed in a neat glass case supported on a bracket on the outside of the tank.

For agitating the chemical solutions each of the tanks is equipped with a two-bladed propeller mounted in a funnel-shaped casing, with its bottom edge supported three inches above the floor of the tank. The propeller will be operated by an electric motor hung from the under side of the tank. The agitation is violent and keeps all inert or undissolved matter thoroughly in suspension until it is drawn off into the piping system. The agitation is particularly good in the corners of square tanks.

The work of constructing the filtration plant was divided into four separate contracts, the first of which was for building the clear-water conduit, intake, and drain. It involved the construction of about 2,900 lineal feet of conduit and was awarded to J. P. Rusche in July, 1910, for $51,518.44. Contract No. 2, for the furnishing and installing of all pumping machinery was awarded to the Fort Wayne Electric Company, who coupled to their motors pumps made by the Buffalo Steam Pump Company, the contract price being $12,425. Contract No. 3 was for the various basins and substructures of the bulidings. It included practically all the grading and the bulk of the concrete work. This contract was awarded to Prang & Co. for $123,842. The fourth contract was for the construction of buildings, wash-water tower, filters, piping, and all the special devices employed in the plant. The Roberts Filter Manufacturing Company, of Philadelphia, were awarded this contract for the sum of $159,882.

All plans for the construction of this plant were prepared by the firm of Hering & Fuller in their New York office, and since the dissolution of the firm. George W. Fuller has been employed as consulting engineer on the construction of the works. The construction has been done under the general supervision of Samuel A. Freshney, secretary and general manager of the Board of Public Works of Grand Rapids, Mr. R. E. Harrison being the resident engineer in direct charge of the work.

Metallurgical Comment

T. R. LOUDON, B.A.Sc.

Correspondence and Discussion Invited

ZINC SMELTING IN ELECTRIC FURNACES.

During the last five or six years electric zinc smelting, inaugurated under the De Laval patents, has been conducted at Trollhattan, in Sweden, and at Sarpsborg, in Norway. Some progress in ore smelting was made, and during 1911 the works were studied by F. W. Harbord, in behalf of the Norse Power & Smelting Syndicate, organized to take them over and enlarge them. The following is a summary of Mr. Harbord's report:—

The Trollhattan works has a furnace building about 300 x 52 ft., equipped with 11 smelting furnaces of the new resistance type, six on one side of the building and five on the other, two refining furnaces and several of the old type of arc furnaces, which at present are not working and are to be replaced by the new resistance type. The furnaces are arranged in two rows, one on each side of the building, the condenser sides of the furnace facing each other.

The furnaces of the resistance type are of 350 horsepower each, having one large vertical electrode passing through the roof, the other electrode being a carbon block bedded in the bottom of the furnace. The ore is charged through the roof. In the more recently erected furnaces the charge opening is on one side of the electrode only. A furnace is being erected with a continuous side-feed, which it is anticipated will give improved results. Two electrodes are fastened together to form the vertical electrode, which then measures 0.218 sq.m. in cross-section and 3 m. in length, its weight being 680 kg. The capacity of each furnace is approximately three metric tons, and the actual smelting is about 2.8 tons of ore per 24 hours.

Current is supplied to the works by a high-tension three-phase system of 9,640 volts and is transformed by single-phase transformers to low-tension single-phase current, the nominal ratio of transformation being 10,000:110. The transformers are of the open type, air-cooled by forced draft from two fans, the average loss of energy across the transformers being 2.5 per cent. of the energy at the furnace. The transformers are situated in a tunnel under the furnace room, each transformer being placed as near as possible and immediately below the furnace to which it is connected.

The smelting process consists in charging the ore, with suitable additions of flux and reducing material (such as anthracite or coke) into the furnace, where most of the zinc and some of the lead are volatilized and condensed, partly as metal and partly as blue powder and oxide, containing about 54 per cent. of zinc and 20 per cent. of lead. This powder is then mixed with fresh ore and recharged, when a much larger percentage of the metal volatilized is recovered as metal. The first operation of smelting ore alone may be regarded mainly as a concentrating process for the production of a rich oxide, which is reduced to the metallic state by subsequent treatment.

The other portion of the lead, carrying a considerable proportion of the silver, is mainly reduced to metal in the smelting hearth and is tapped out with the slag. Some of the lead, zinc and silver passes into the matte and some into the slag.

In the test conducted by Mr. Harbord and assistants, the following were the charges first used, four furnaces working on ore-powder mixture and three furnaces on ore mixture: Ore powder mixture; Broken Hill slime (roasted), 100 kg.; powder, 200 kg.; coke dust, 25 kg.; lime, 5 kg. Ore mixture: Broken Hill slime, 300 kg.; calamine, 10 kg.; coke, 75 kg. At the end of the second day the ore furnaces were making sufficient powder to supply the powder furnaces (powder had previously been taken from the works stock in order to start the test) and from this time until the end of the run no further powder was taken from stock. The furnaces were tapped every four hours for crude zinc and powder, and the slag, matte and lead were tapped about every eight hours. During the run a good deal of trouble was experienced from break-outs of lead near the bottom of the furnace, due evidently to the furnace bottom becoming saturated with lead.

During the early part of the run the slags were far from clean, containing large quantities of zinc and lead, chiefly due to imperfect separation of the matte, which in turn was due to imperfect mixing of the charge and to the slags being too basic, owing to improper proportions of flux and reducing agent. Later on the slags improved considerably, although not infrequently two furnaces working side by side on the same mixture would give totally different slags, showing clearly that this was due to some outside cause, like irregular mixing.

Another serious trouble was the removal of electrodes, which caused very considerable delay, due to a great extent to the defective mechanical appliances for removing and replacing the parts. The average time for changing an electrode was 150 min., whereas it should easily be done in 30 min. with proper appliances. Although there were various minor troubles, there was no serious stoppage caused by failure of the furnaces.

During 27.58 days of the experimental run, the furnaces smelted 518 metric tons of Broken Hill slime (roasted)) 19 tons of calamine and 22.5 tons of blue powder (from stock); and produced 160.8 tons of crude zinc and 36 tons of powder. The powder produced by the different furnaces was recharged with fresh ore, a portion each time being reduced to metal, and the final result at the end of the run was 13.4 tons more powder on hand than at the beginning. The crude metal obtained from this smelting averaged about 79 per cent. zinc, 20 per cent. lead and 0.6 per cent. iron. This was afterward refined, with a production of 112.4 tons of spelter (assaying 99.9 per cent. zinc) and 24.7 tons of lead. The lead tapped with the slag was remelted, in order to remove the slag. This yielded 41 tons of marketable bullion, containing 141 oz. of silver per ton. In addition to this there was obtained 17 tons of leak-lead, assaying 27 oz. of silver per ton. There were also nearly nine tons of skimmings containing zinc, lead and silver. The total input of metals was 204.04 tons of zinc, 128.35 tons of lead and 15,750 oz. of silver. The extraction in the form of metals was 130.46 tons of zinc, 94.94 tons of lead and 7,230 oz. of silver, showing a yield of 64 per cent., 73.99 per cent. and 45.9 per cent. respectively. If the metals in the powder be included the percentage yields are 73.4 zinc., 79.3 lead and 49.5 silver. Mr. Harbord considered that the losses of lead and silver were unduly large because of the retention of some of those metals in the masonry of the furnaces.

Mr. Harbord was of the opinion that the method of charging through the roof leaves much to be desired and anticipates much better results from side charging. Very considerable quantities of valuable fine dust were lost, owing to inadequate arrangements for its collection. A modern bag house, or its equivalent, would lead to an increased

recovery of dust. He says furthermore: "The weak point of the process is the large amount of metallic powder produced in proportion to the metals. The recovery of a large percentage of metals as metals is admittedly a very difficult problem, but that the present practice can be very greatly improved upon, I have not the least doubt, leading to decreased consumption of energy and reduction of labor cost.

One detail, which is a great improvement on the early practice, is the better separation of the crude zinc from the powder by a mechanical stirrer, which was only tried just before we commenced out investigation."

At Trollhattan practically the whole of the crude zinc made during the experimental run was afterward refined. Out of 111,794 kg. of crude zinc there was obtained 78,136 kg. of fine zinc, 17,179 kg. of lead and 11,209 kg. of powder (corresponding to 10,088 kg. of metals). Consequently, there was a loss (unaccounted for) of 5.7 per cent. This loss was distinctly higher than the average, as shown by the records of the works over a considerable period, and probably is explained by the new brick work continuing to absorb some of the metal. In the refining of commercial spelter at Sarpsborg the average practice has been as follows: Fine zinc, 83.9 per cent.; powder 9.8 per cent. (corresponding to 8.8 per cent. metals); residues (lead, etc.), 2.20 per cent.; charge in furnaces, 1.1 per cent.; impregnation in brickwork of furnaces and condensers, 0.5 per cent.; unaccounted for, 3.5 per cent.; total, 100 per cent.

Mr. Harbord also conducted an experimental run at Sarpsborg. The works at that place have three smelting furnaces of the old arc type and four refiners. During 20 days he smelted 133 metric tons of Broken Hill roasted slimes and three tons of calamine. For the first day, to enable two out of the three furnaces to be put on powder mixture about 3.5 tons of powder were borrowed from the works stock, but after the first 24 hours sufficient powder to supply two furnaces was made, the third being kept on ore charge alone until within about 36 hours of the finish of the run, when powder was charged with the ore to use up some of the excess stock made during the run. The furnaces worked very well and gave no serious trouble, but the slags were far too basic and contained very large percentages of both zinc and lead, and at no time during the trial run was any matte obtained separate from the slag, the latter being really a mixture of slag and matte. During the run 43 tons of crude zinc and 12 tons of tap lead, containing 191 oz. silver per ton, were obtained. No leakage lead from the furnace bottoms was obtained. The crude spelter contained 74.74 per cent. zinc, 24.57 per cent. lead, and 0.7 per cent. iron.

The consumption of electric current in the experimental run at Trollhattan averaged 2,078 kilowatt-hours per ton of ore smelted. The cost of power at Trollhattan is at present 30s. 3d. per horse-power-year, or 41s. 3d. per kilowatt-year.

The arc furnace, so far as the process of actual smelting is concerned, was found to give just as good results as the resistance furnace, but the consumption of energy was over 70 per cent. more. The method of hand feeding the electrode was slow and unreliable, especially as regards keeping the arc in the centre of the furnaces. The consumption of electrodes also was materially higher than in the case of the resistance furnaces. At Trollhattan the average consumption of electrodes was 31.51 kg. per 1,000 kg. of ore smelted; at Sarpsborg it was 40.57 kg. per ton of ore. If it be decided to continue smelting at Sarpsborg, the old type of arc furnace will have to be replaced by resistance furnaces.

THREE-PHASE CURRENT FOR MERCHANT MILL DRIVING.

C. A. Ablett.

The roughing rolls of a merchant mill should be run at the highest speed at which it is found practicable for the men to catch the comparatively short billet, and as in most cases about the same size of billet is being rolled the speed should remain constant. The finishing rolls, on the contrary, should be capable of running at a large number of different speeds according to the shape and weight of section being rolled.

Light sections which cool rapidly must be rolled at a high speed so as to finish them while hot, but with heavier sections the rate of cooling is slower, so that there is not the necessity for rolling at a high speed, while there is the advantage that better material is obtained if the speed of rolling is lower.

The slowest speed is required for "hand rounds" where the roller has to guide a bar of oval section with his tongs through a round hole so that the biggest diameter of the oval stands upright, and unless the speed is low the roller cannot follow up the bar.

If the roughing and finishing mills are coupled together and driven by one motor, it will not be possible to run at a sufficiently high speed for the light sections on account of

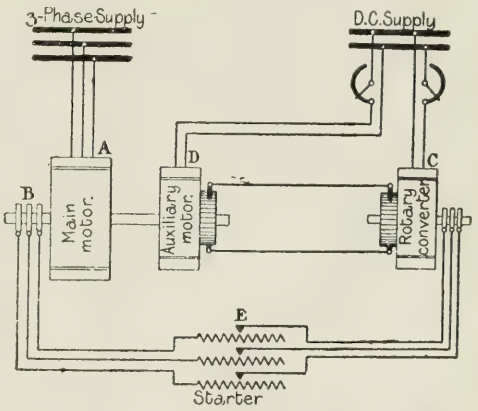

Fig. 1.—Diagram of Connections of High-Efficiency, Variable-Speed, Three-Phase Rolling Mill Motor Set.

the roughing mill, so that the roughing mill will restrict the output of light sections, while on the other hand, when rolling "hand rounds" the low speed of the finishing mill will require that the roughing mill also go at a low speed and the output be also restricted. With such a mill the proper outputs can only be obtained at the medium speeds. The ideal drive, therefore, is to provide a constant-speed motor for the roughing mill and a separate variable-speed motor for the finishing mill, and when this is done the roughing mill is usually placed in tandem with the finishing mill.

Where the power available is direct current, this arrangement presents no difficulty, but where three-phase current must be used, the means of providing a variable-speed drive for the finishing mill needs some consideration.

A still more economical arrangement for obtaining variable speed has been adopted for three merchant mills in this country. (Fig. 1.) This consists of employing a three-phase motor direct coupled to a direct-current motor for driv-

* Abstracted from a paper read before The Institution of Electrical Engineers.

ing the mill. A rotary converter is connected to the rotor circuit of the three-phase motor, so that when the set is run at reduced speed the power which would otherwise be wasted in resistances in the rotor circuit is converted by the rotary converter from three-phase to direct-current, and then used usefully to supply the direct current motor.

Comparing this scheme with that of converting all the three-phase power to direct current and installing a direct-current rolling mill motor, it should be pointed out that in this latter scheme the rotary converter and the direct-current motor do not have to deal with the entire power, but with a power proportional to the amount that the main three-phase motor is running below synchronous speed. The conversion losses are therefore reckoned on a fraction of the power, and not of the entire power, so that the arrangement is much more efficient. Further, the rotary converter and the direct-current motor are proportioned for a fraction of the power instead of the whole power, so that they can be small machines. The arrangement, therefore, is cheaper in capital cost. With this arrangement, the direct-current motor is provided with a compound winding to act as a continuous-slip regulator, and the combination behaves like an ordinary compound-wound direct-current motor, the speed being varied by altering the resistance of the shunt field circuit of the direct-current motor, while with the exception of that variation in speed necessary to enable the flywheel to give up and regain part of its stored energy, the mill motor set runs at the required speed and does not give trouble by attempting to increase in speed up to the maximum speed between the passes.

Generally speaking, where there is a choice between direct current or three-phase for driving a mill for which variable speed is desirable and there is little or no difference in the cost of current, the adoption of direct current will be found the most economical.

Friction Losses.—Particular care should be taken to reduce as much as possible the friction losses, or other such losses which have a constant steady value independent of the power which the rolling mill may be giving, because, generally speaking, the power taken by a motor driving a rolling mill varies between wide limits so that the average power taken is very much less than the rated output of the motor, and any losses such as those due to friction, which go on continuously, very considerably increase the number of units of electricity used in a given time.

This is a point which is very liable to be overlooked, because such losses are usually stated as a percentage of the rated output, as is often the case, a friction loss which may average power of a rolling mill motor is one-third of its rated output. as is often the case, a friction loss which may be only 10 per cent. of the rated output will increase the total units consumed in a given time by 30 per cent. Such friction losses may be caused by the friction in the flywheel bearings, or by the windage of the flywheel itself or in the drive used to transmit the power of the motor to the mill in those cases where the mill motor is not direct coupled.

To take a practical example, the case of some tinplate mills may be considered which require a 450 horse-power motor, where the power varies between very considerable limits, and where there is a choice between installing a high-speed motor driving the mills through a rope drive, or installing a slow-speed motor direct coupled to the mill.

It may be assumed that the loss in the rope drive is 10 per cent. of the full-load power of the motor, that the efficiency of the slow-speed motor is 2 per cent. less than that of a high-speed motor, and that the actual power consumption required by the mill apart from the drive is 15,000 units per week. If a slow-speed motor be installed, 2 per cent. must be added to the 15,000 units on account of the low efficiency, so that the units consumed in the week will be 15,300. If the 450-b.h.p. motor ran steadily at its full power, making due allowance for 5 per cent. loss in slip resistance, etc., the steady input would be 385 kw.; therefore, if the motor ran steadily at its full power for a week of 120 working hours it would consume 45,000 units. Ten per cent. of this, or 4,500 units, are wasted in the rope drive, so that if the high speed motor with the rope drive be installed, the total units consumed per week will be 19,500, or 4,200 more than if a slow-speed motor be used. Supposing that the cost of power is 0.5d. per unit, the extra 4,200 units used per week will cost £8 15s., or £437 10s. per annum. This saving would justify a very considerable extra capital expenditure on a slow-speed motor.

The question of electrical driving is seldom raised without comparisons being made between the cost of driving rolling mills by steam or by electricity, but it is outside the scope of this Paper to revive this well-worn subject. Various economies can be effected by the electrical driving when properly applied, but one of the principal economies is that of the cost of power. The electrical drive often enables cheap power to be used when it could not be transmitted or applied in any other way, and also in many cases it affords a means of enabling power to be generated cheaply.

Where cheap power is available it must be applied as economically as possible, and it will be seen from what has been said in the foregoing that considerable care must be exercised in applying a motor and flywheel to a rolling mill in order to ensure that the power is utilized as cheaply as possible if it is desired to obtain economy in working.

THE PROPOSED MACKENZIE AND MANN STEEL PLANT.

The newspapers of late have published material descriptive, to a more or less extent, of the proposed steel works for Port Arthur, Ont.

It is stated that the Mackenzie and Mann interests are going to spend approximately $8,000,000 in establishing new industries at Port Arthur, $5,000,000 of which are for the steel works.

The Port Arthur Board of Trade, in their literature of late, have drawn attention to the fact that pyrites of iron and copper, also other iron ores, were to be found in quantity in the vicinity of Port Arthur.

The financial interests supporting this scheme, according to report, will commence operations in the spring of 1912, upon the erecting of numerous factories on the water front. They intend to establish a steel plant, comprising blast furnaces for the smelting of iron ore, rolling mills, merchant mills, steel rail mills, burr mills, ore docks, coal docks and a gas plant. This report further states that the plant will utilize 7,000 horse power, which will be developed from either Dog Lake or the Nepigon river. The preference is given to the Nepigon river as a source of electrical energy. This development will mean an additional expenditure of approximately $2,000,000.

The gas plant will be one of the best in Canada. The company will dispose of the surplus supply to the citizens at a nominal price. Part of the plant will be erected on the property at present owned by the company on the south side of the Canadian Northern elevators, and for the other works the company is negotiating with the city council for land near Bare Point. It is not yet known the extent of the property required, but the company will ask for certain bonuses.

COKE PRODUCTION OF CANADA.

The statistics of coke production in Canada as compiled by Mr. John McLeish, B.A., in his report to the Department of Mines, Ottawa, do not include coke made as a by-product in the manufacture of illuminating gas but are restricted to the record of the output of "oven coke" produced chiefly for metallurgical purposes.

The total output of coal in 1910 was 901,269 tons produced from 1,373,793 tons of coal; of which 875,310 tons were produced from domestic coal and 25,959 tons from imported coal. In 1909 the total production was 871,727 tons produced from 1,327,150 tons of coal.

The quantity of coke sold or used by the producers in 1910 was 902,715 tons, as compared with 862,011 tons in 1909. The consumption of coke in Canada is much in excess of the domestic production, there being a considerable importation of coke chiefly into Ontario and Quebec for use in the metallurgical industries.

The imports of coke during the calendar year 1910 were 737,088 tons and the exports 57,971. These figures taken in conjunction with the production of 902,715 tons (sold or used), would indicate a consumption of 1,581,832 tons. Similarly estimated the consumption in 1909 was 1,449,369 tons, and in 1908, 1,285,228 tons.

Coke is made in Nova Scotia, principally at Sydney and Sydney Mines, but also at Westville, Stellarton, and Londonderry. This province in 1910 produced about 56 per cent. of the total for Canada, and the ouutput is used almost entirely in the manufacture of iron. In Ontario coke is made by the Atikokan Iron Company at Port Arthur for use in the company's blast furnace. By-product ovens are also being erected by the Algoma Steel Company at Sault Ste. Marie, to supply fuel for the company's blast furnaces. For both these plants coal is imported from the United States. In Alberta coke ovens are operated at Coleman and Lille near Blairmore, and in British Columbia at Fernie, Michel, Carbonado, and Hosmer in the Crows Nest Pass, and at Union Bay, Vancouver Island. The coke output of these provinces is used chiefly by the copper and lead smelters; finding a market in the United States as well as in British Columbia.

The total number of ovens in active operation on December 31 was 1,678; while 1,086 were reported idle on the same date, and 230 in course of construction. In Nova Scotia the Dominion Iron and Steel Company at Sydney has 500 finished ovens and 120 in course of construction, all of the Otto Hoffman by-product type. The by-products from these ovens include tar and ammonia. The tar is sold to the Dominion Tar and Chemical Company, whose works are contiguous to the coke oven plant, and this product is further treated for the manufacture of refined tar, pitch of various grades, benzole, creosote, carbolic acid, etc. The production of tar in 1910 was 3,963,591 gallons, and ammonia liquor containing 3,491 tons of sulphate of ammonia.

In 1909 the production of tar was 4,016,824 gallons, and of sulphate of ammonia 3,351 tons; and in 1908, tar 4,450,166 gallons, and sulphate of ammonia 2,984 tons. The Nova Scotia Steel and Coal Company has 30 ovens of the Bauer type and 120 Bernard ovens; the latter are situated near the furnace and the surplus gas is used for the production of steam for the electric power plant. The surplus gas from the Bauer ovens is used in generating steam for general colliery use. The other ovens in this province number 178 and are all of the beehive type. The Atikokan Iron Company, Limited, has 100 beehive ovens at Port Arthur, Ont., and the Algoma Steel Company is erecting 110 Koppers by-product regenerative coke ovens at Sault Ste. Marie. The company has acquired and is operating coal lands in West Virginia for supply of coal.

In Alberta the West Canadian Collieries, Limited, at Lille, has 50 ovens of the Bernard or Belgian type. The ovens of the International Coal and Coke Company at Coleman, 216 in number, are the ordinary beehive as are also the ovens in British Columbia, comprising 1,420 in the Crow's Nest district and 150 on Vancouver Island.

Coke is manufactured from coal mined in five of the coal basins in Canada, viz.: the Sydney field, the Pictou field, both in Nova Scotia; the Frank-Blairmore field in south-western Alberta; the Crow's Nest field in East Kootenay, and the Comox field on Vancouver Island, both of the latter in British Columbia.

In the Sydney field the ovens used are all by-product ovens, whereas the coal of the Pictou field is made into coke in beehive ovens. A certain amount of Springhill coal, Cumberland field, is mixed with this coal, which it has not been possible to separate to calculate the yield in coke.

In the Blairmore field both Belgian ovens and beehive ovens are used. On Vancouver Island the coke is made in beehive ovens.

It may be interesting to point out that in this last field, only the fine screenings are used in the manufacture of coke. This coal is thoroughly washed before being charged into the ovens, and the refuse resulting from this treatment often amounts to 50 per cent. This refuse is rejected, and only the washed coal is charged into the ovens. The yield is computed from the quantity of washed coal.

THE PERMANENT EXPOSITION OF RAILWAY SUPPLIES.

Railway men in all sections of the country are evincing interest in the Permanent Manufacturers' Exhibit Railway Supplies and Equipment which is established in the Karpen Building, 900-910 South Michigan Boulevard, Chicago. This Exposition, which covers the entire 12th floor of one of Chicago's more recently constructed office buildings, is intended to be a permanent showing of machinery, equipment and supplies of every character used by the modern railway system.

A floor space containing over twenty-six thousand square feet has been divided into booths of various sizes to suit the requirements of the exhibitor. The booths are separated by heavy brass rails and each is furnished with standard equipment. As a result, all booths will be uniform and all appointments, including signs, will be of the same uniform character.

It is intended to make this exhibit the headquarters of visiting railway men, and to this end ample facilities have been provided for their entertainment. In connection with the Exposition, there are assembly and committee rooms. These have been placed at the disposal of the various railway organizations for meeting and convention purposes. The assembly room is capable of seating 400 people and has perfect light and ventilation, together with every facility for the transaction of association business. The club rooms have all the appointments of a modern club, and it is expected that this feature will attract a large number of visiting railway men to the Exposition.

Many of the largest firms in the country manufacturing supplies and equipment have already contracted for space in the Exposition, and a considerable number of exhibits have been installed. More are being placed daily, and by the time the Exposition is thrown open to the public on March 16th—which date has been set for the opening—every inch of floor space will be occupied.

The displays will be of a diversified character, and practically every line of the railway supply trade will be re-

presented. Working models of various devices will be shown, and some of the manufacturers are installing very elaborate displays of their goods.

The object of the exposition is to show under one roof practically every line in which railway men are interested. The educational value of the Exposition will be considerable, inasmuch as new devices will be displayed here as soon as they are brought out and the railway interests of the country will have an opportunity of inspecting the various lines without the expenditure of the time and money which would be required to visit the headquarters of the manufacturers. All of the space of the present floor will be devoted to machinery and the like, and plans are already being made to broaden the scope of the Exposition by the addition of another floor, which will be devoted exclusively to maintenance of way equipment.

ELEVATORS FOR C.P.R. BUILDING, TORONTO.

The new Canadian Pacific Railway Office Building at the southeast corner of King and Yonge Streets, Toronto, will be one of the notable features of that city. Its sixteen stories, for example, will tower above the fifteen stories of its neighbor, the Traders Bank Building, which now holds the record for height. The elevator service will naturally be of the utmost importance to the success of the building for office purposes, and the company has decided to spare no expense on the installation. After careful investigation the company chose the plunger type of elevator, and awarded the contract to the John McDougall Caledonian Iron Works Company, Limited, of Montreal.

There will be five hydraulic direct plunger elevators with the necessary pumping and signaling equipment. Three of these elevators for passenger service will have a lift of 188 feet and one of them a lift of 199 feet. The fifth, used for ashes, etc., will have a smaller lift. As they will be plunger elevators it will be necessary to sink wells of corresponding depth and line them with steel pipe casing. The passenger elevators will, of course, be provided wih every modern device to secure speed and safety in operation, including automatic limit stops which, quite independently of the operator, will slow the speed down gradually at the top or bottom without any shock or vibration. The elevators will be operated by Worthington compound steam pumps, and will be directed by an elaborate flash light signal system. In general features these elevators will be similar to those built by the same company for the new C.P.R. Windsor Station, Montreal.

ENGINEERING NOTES.

Edmonton, Alta.—The revenue from the operation of the municipal street railway for January, 1912, amounted to $26,408, an increase of 81 per cent. over January, 1911.

Newfoundland.—The Governor of this colony, Sir Ralph Champney Williams, announces the intention of the government to extend the roads, build additional costal steamers and improve the telephone and telegraph systems.

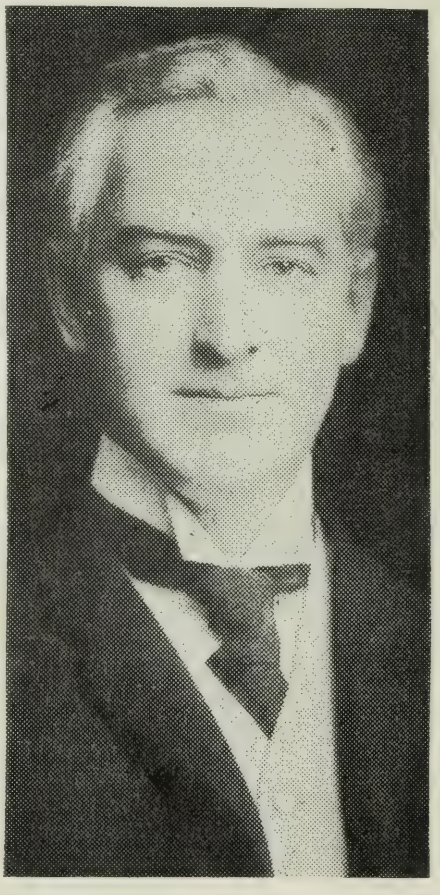
Union Bay, B.C.—A dam at a small lake near Union Bay was destroyed on February 12 last. The cause of the disaster is believed to be heavy rains. The dam was used to generate power for the plant of the Canadian Collieries and was owned by Mackenzie & Mann.

Railway Locomotives.—Canadian railways within the past two months have ordered two hundred and sixty new locomotives, representing a capital outlay of about four million dollars. Of the total 175 are for the Canadian Pacific, 85 being from the American Engine and Locomotive Company, and the rest from Canadian shops, sixty for the Canadian Northern, and twenty-five for the Grand Trunk Pacific.

Vancouver, B.C.—A new gasometer being erected for the Vancouver Gas Company will have a capacity of 2,000,000 cubic feet of gas. It has a diameter of 150 feet and the steel towers of the structure rise to a height of 160 feet from the foundation line. Each of the telescopic lifts of the holder is 31 ft. 6 in. in depth and fitted with the latest types of guides, rollers, carriages, etc., from its up and down movement as limited by the lofty guide frames when a fresh supply of gas is poured in or the storage supply is drawn upon. The water tank on the ground level is of a depth of 32 ft. 6 in. and is formed of steel plates varying in gauge from ⅞ to ⅜-inch. The capacity of this water tank is approximately 3,500,000 gallons. When the new gas holder is in service the company will have at its command a storage capacity equivalent to two and a half days demand at the present rate of consumption of gas in the city.

PERSONAL.

Mr. T. Kennard Thomson, a graduate of Toronto University, has made a specialty of tall building foundations. As an authority on caisson air chambers he is known to many owners of financial buildings in lower New York. Among many of these buildings, which have had their foundations examined and planned by Mr. Thomson, are the Manhattan Life Building, the Civic Investment Building, the Trust Company of America, the Singer Building, and the Tower of Liberty. Mr. Thomson was born in Buffalo, 1864.



Mr. K. S. Macdonnell, municipal engineer for the City of Collingwood, Ont., has tendered his resignation, to take effect March 1st.

Mr. J. T. Arundel, of Winnipeg, has been appointed superintendent of the Ontario division of the Canadian Pacific Railway.

J. R. Wemlinger, president Wemlinger Steel Piling Company, 11 Broadway, New York, has been re-elected secretary of the American Society of Engineering Contractors, with headquarters at 13-21 Park Row, New York.

Alexander Potter, consulting engineer, 114 Liberty Street, New York, has just been retained by the City of San Antonio, Texas, to make an appraisement of existing waterworks owned by San Antonio Water Supply Company, and to prepare plans for future extensions. Mr. Potter has also just recently been engaged by the City of Springfield, Mo., to design sewage disposal plans for two extending outlets, one to the north and one to the south.

CANADIAN MINING INSTITUTE.

The provisional program for the annual meeting at Toronto is as follows: Wednesday, March 6, at 10 a.m., business meeting, at which the usual current business will be dispatched, the presidential address delivered, and the mineral statistics for 1911 presented. In the afternoon there will be a meeting for reading and discussion of papers; and in the evening Dr. W. H. Tolman, director of the American Museum of Safety, will deliver an illustrated address on "Accident Prevention." On March 7 there will be morning and afternoon sessions for reading and discussion of papers, and in the evening a smoking concert. On March 8, morning and afternoon sessions for reading and discussion of papers, and for the dispatch of any unfinished business will be held. In the evening the meeting will close with the annual dinner.

INTERNATIONAL GEOLOGICAL CONGRESS.

Dean Adams, of McGill University, presided at a meeting in Montreal the other day of representatives of the Canadian Mining Institute and the railways to make preliminary arrangements for the entertainment of the numerous delegates coming from all over the civilized world to attend the International Geological Congress, to be held in Montreal in the summer of 1913.

The ten days' sessions are to be held in Toronto, but the delegates will foregather in Montreal for two weeks prior to these meetings, and will undertake excursions into all the surrounding country interesting from a mineral or geological point of view. It is expected that there will be over 700 delegates from outside countries, including Great Britain, Germany, France, Spain, Italy, Finland, Russia, Servia, India, Africa, Australasia, China, Japan, Belgium, Sweden, and other places. There will also be delegates from all parts of North and South America, so that over 1,000 will be in session. From Montreal excursions are to be made to the Maritime Provinces, to the Haliburton and Bancroft area, to Sudbury, Cobalt and Porcupine, to Thetford Asbestos Mines, to the St. Marguerite and St. Jerome anorthosite deposits, to the Monteregian Hills, and to the Ottawa and Kingston districts. During the sessions in Toronto, excursions will be made to different parts of Ontario, and after the sessions there will be excursions to the Pacific Coast, the Yukon and Alaska Districts, and to the Peace River and Athabasca regions.

The Dominion Government has already taken steps for the entertainment of the visitors, and to help in showing them the mineral resources of the country, and it is believed the visit of so many famous geologists will have an important effect on the future development of the country.

MEETING OF OTTAWA BRANCH, CANADIAN SOCIETY OF CIVIL ENGINEERS.

A meeting of the Ottawa branch of the Canadian Society of Civil Engineers was held on February 5th, to discuss the action taken at the annual meeting in regard to the erection of a headquarters building at Montreal. The following motion by Mr. Noulan Cauchon, seconded by Mr. A. A. Dion, was carried:

"That it is the opinion of the Ottawa branch of the Canadian Society of Civil Engineers, that in view of the fact that the branches are not getting sufficient funds for their proper maintenance and progress:

"That this branch views with regret as hasty the action taken by the annual meeting in voting to dispose of practically all the funds of the society for a new headquarters without taking a ballot of the society on the subject."

It was moved by Mr. G. B. Dodge and seconded by Mr. S. S. Johnson, "That the above motion be forwarded to all other branches of the society."

ANNUAL MEETING OF AMERICAN ROAD BUILDERS' ASSOCIATION.

The annual meeting of the American Road Builders' Association was held at the Hotel Astor, New York City, N.Y., February 2nd. At this meeting reports of the executive committee, the secretary, and the treasurer were presented. Their reports showed a very healthy and substantial growth during the past year, the membership having increased very materially. Prospects for a much larger increase the present year are exceedingly bright.

The election of the officers of the association is by letter ballot. At this meeting the ballots were counted and officers were declared elected as follows:—

President, Nelson P. Lewis, Chief Engineer Board of Estimate and Apportionment, New York City.

First Vice-President, Harold Parker, Ex-Chairman Mass. State Highway Commission, Worcester, Mass.

Second Vice-President, J. D. Meriwether, Territorial Road Engineer, Socorro, N. Mexico.

Third Vice-President, W. A. McLean, Provincial Engineer of Highways of Ontario, Toronto, Ont., Canada.

Secretary, E. L. Powers, Editor and Publisher "Good Roads," New York City, New York.

Treasurer, W. W. Crosby, Chief Engineer State Roads Commission, Baltimore, Md.

Directors for Three Years: A. W. Dean, Chief Engineer, Massachusetts Highway Commission, Boston, Mass. F. D. Lyon, Deputy Commissioner of Highways, Albany, New York. P. L. Hardison, State Highway Commissioner, Augusta, Maine. S. D. Foster, Chief Engineer Highway Dept., Harrisburg, Pa. W. J. Roberts, State Highway Commissioner, Olympia, Washington.

Clifford Richardson, Consulting Engineer, New York City, N.Y.

MEETINGS.

Major W. R. Lang addressed the Engineers Club on the evening of February 15th and drew the attention of that body to the establishment of military engineering units of

service to the infantry. Major Lang stated that the proportion of engineers to infantry in Canada was far too small, and advocated the extension of this branch of the service.

Professor A. P. Coleman, University of Toronto, addressed the members of the Canadian Clay Products Association at Halifax, N.S. He selected as his subject "The History and Nature of Clay."

Professor Parker delivered a lecture on the "Chemistry of Flames" before the public, at the University of Manitoba, on February 9th last. The address was illustrated by experiments, etc.

Mr. Collingwood Schreiber, C.M.G., read a paper on "The Development of Transportation Facilities in Canada" before the Canadian Society of Civil Engineers, at Montreal, on the evening of February 8th last. The construction of small canals in the 18th century in Canada around some of the rapids of the St. Lawrence and Ottawa Rivers, up to the construction of the Coteau de du Lac and Split Rock Canals in 1779, their enlargement in 1814 to 1817, and the making of the Vaudreuil, Lachine, Welland, Carillon and Grenville, Rideau, Trent, and Cornwall Canals, were traced by the speaker, who also referred to the development of the railway system from the first line constructed in 1836 between Laprairie and St. John, up to the present day.

COMING MEETINGS.

THE UNIVERSITY OF TORONTO ENGINEERING SOCIETY.—Open Meeting of Engineering Society at 4 p.m., Thursday, Feb. 22nd, 1912, in Convocation Hall. Mr. Frank B. Gilbreth, Efficiency Engineer and Contractor, New York City, will lecture on the subject of "Scientific Management." Cor. Secretary, Allan A. McQueen.

THE CLEVELAND ENGINEERING SOCIETY. Special Meeting February 27, 1912, Chamber of Commerce Building, Cleveland, O. "Technical Education (Illustrated)," by Prof. J. F. Barker, Technical High School, Cleveland. Secretary, F. W. Ballard.

ONTARIO GOOD ROADS ASSOCIATION.—Annual Convention to be held at Toronto, February 26, 27, 28. Secretary, J. E. Farewell, Whitby.

ASSOCIATION OF ONTARIO LAND SURVEYORS.—Annual Meeting to be held in Lecture Room, Engineers' Club, 96 King Street West, Toronto, on Feb. 27, 28 and 29. Secretary, Killaly Gamble, 703 Temple Bldg., Toronto

THE ENGINEERS' CLUB OF TORONTO, 90-96 King St. West.—Thursday, Feb. 29th, 8 p.m. Meeting of Toronto Branch of Canadian Society of Civil Engineers. R. B. Wolsey, Secretary.

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE; Secretary, Professor C. H. McLeod.

QUEBEC BRANCH—
Chairman, P. E. Parent; Secretary, S. S. Oliver. Meetings held twice a month at Room 40, City Hall.

TORONTO BRANCH—
96 King Street West, Toronto. Chairman, T. C. Irving; Acting Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the month at Engineers' Club.

MANITOBA BRANCH—
Secretary E. Brydone Jack. Meets every first and third Fridays of each month, October to April, in University of Manitoba, Winnipeg.

VANCOUVER BRANCH—
Chairman, Geo. H. Webster; Secretary, H. K. Dutcher, 319 Pender Street West, Vancouver. Meets in Engineering Department, University.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, S. J. Chapleau, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings,

MUNICIPAL ASSOCIATIONS.

ONTARIO MUNICIPAL ASSOCIATION.—**President, Chas. Hopewell, Mayor, Ottawa; Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.**

UNION OF ALBERTA MUNICIPALITIES.—President, H. H. Gaetz, Red Deer, Alta.; Secretary-Treasurer, John T. Hall, Medicine Hat, Alta.

THE UNION OF CANADIAN MUNICIPALITIES.—President, W. Sanford Evans, Mayor of Winnipeg; Hon. Secretary-Treasurer, W. D. Lighthall, K.C., Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer, J. W. McCready City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bec, Lemberg; Secretary, Mr. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

CANADIAN TECHNICAL SOCIETIES.

ALBERTA ASSOCIATION OF ARCHITECTS.—**President, G. M. Lang;** Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—**President, J. L. R. Parsons, Regina;** Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—**President, N. McMurchy;** Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—**President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.**

BUILDERS, CANADIAN NATIONAL ASSOCIATION.—**President, E. T. Nesbitt; Secretary Treasurer, J. H. Lauer, Montreal, Que.**

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—**President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.**

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—**President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto.**

CANADIAN ELECTRICAL ASSOCIATION.—**President, N. W. Ryerson, Niagara Falls;** Secretary, T. S. Young, **Canadian Electrical News, Toronto.**

CANADIAN FORESTRY ASSOCIATION.—President, John Hendry, Vancouver. Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—**President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; J. Keillor, Secretary-Treasurer, Hamilton, Ont.**

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—**President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.**

CANADIAN MINING INSTITUTE.—**Windsor Hotel, Montreal. President,** Dr. Frank D. Adams, McGill University, Montreal; Secretary, H Mortimer-Lamb, **Windsor Hotel, Montreal.**

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, D. McDonald, Manager, Montreal Street Railway; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto, President, G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July, August.

DOMINION LAND SURVEYORS.—President, Thos. Fawcett, Niagara Falls; Secretary-Treasurer, A. W. Ashton, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, W. B. McPherson; Corresponding Secretary, A. McQueen.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President, Killaly Gamble; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. **Canadian Members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain, and W. H. Miller, and Messrs. W. H. Trewartha-James and J. B. Tyrrell.**

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary, R. C. Harris, City Hall, Toronto.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C.B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, W. H. Pugsley, Richmond Hill, Ont.; Secretary, J. E. Farewell, Whitby.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, J. Whitson; Secretary, Killaly Gamble, 703 Temple Building, Toronto.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, F. S. Baker, F.R.I.B.A., Toronto, Ont.; Hon. Secretary, Alcide Chausse, No. 5 Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Dr. A. McGill, Ottawa, President; Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, J. P. McRae; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Wm. Pierce, Calgary; Secretary-Treasurer, John T. Hall, Brandon, Man.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. Rosevear, 115 Phœnix Block, Winnipeg, Man. Second Monday, except June, July and August, at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc.
Printed forms for the purpose will be furnished upon application.

TENDERS PENDING.

In Addition to Those in this Issue.

COPIES WANTED.

Copies of our issue of February 1st and 8th are required. Parties sending in same will be allowed the usual extension in their subscription.

TENDERS.

Brantford, Ont.—Tenders will be received up to Friday noon, 23rd February, 1912, for the construction of concrete abutments for a bridge to be built for the municipality of the township of Brantford over Fairchild's Creek. Plans and specifications to be seen at the office of James A. Smith, township clerk, Brantford.

Brantford, Ont.—Tenders will be received until February 29, 1912, for the supply of sewer pipes required by the City of Brantford during 1912. T. Harry Jones, city engineer, City Hall, Brantford. (See advertisement elsewhere in Canadian Engineer.)

Calgary, Alta.—Tenders for one or more of the following buildings will be received at the office of C.P.R. Division Engineer, Calgary, up to noon February 24th, 1912, for the erection and completion of the following buildings: Western Lines Class "A" Station at following points:—Webb, Namaka, Seven Persons, Winnifred, Dunmore, Clive, Nevis, Lougheed, Aldersyde, Jeffray, Burmis and Galloway. Also a Western Lines Standard No. 5 Sattion at Yahk. Plans and specifications can be seen at Chief Engineer's Office, Winnipeg; Resident Engineer's offices at Cranbrook and Medicine Hat, and this office. N. E. Brooks, C.P.R. Division Engineer, Calgary.

Calgary, Alta.—Tenders will be received until noon of May 1st, 1912, for proposals for Brooks Aqueduct. Plans, etc., may be obtained on application to A. S. Dawson, chief engineer, C.P.R., Calgary. (See advertisement elsewhere in Canadian Engineer.)

Edmonton, Alta.—Tenders will be received until March 15th, 1912, for the manufacture of all steel highway bridges required for the year 1912. Specifications, etc., may be had from the Structural Engineer's Office, Department of Public Works, Edmonton. John Stocks, Deputy Minister of Public Works, Edmonton.

Moose Jaw, Sask.—Tenders will be received until March 18th, 1912, for laying about 96,000 lineal feet of 18-inch steel water pipe. E. B. Bonnell, City Clerk, Moose Jaw. (See advt. elsewhere in Can. Eng.)

Montreal, Que.—The Canadian Pacific Railway are contemplating the erection of a steel bridge, grading, etc., at Ingersoll, Ont. Estimated cost, $30,000. Supt. in Charge, Mr. Hodge, London.

Ottawa, Ont.—Tenders will be received until March 4, 1912, for the supply of coal and fuel wood required to heat the military buildings at Toronto, Hamilton, Brantford, St. Catharines, Dundas, and Burford, Ont., for the year ending March 31st, 1913. Full particulars to be had on application to the director of contracts, Militia Headquarters, Ottawa, or at the office of the Officer Commanding 2nd Division, Toronto. Eugene Fiset, Col., Deputy Minister of Militia and Defence, Ottawa.

Ottawa, Ont.—Tenders will be received until March 6th, 1912, for the construction of a dormitory, Royal Military College, Kingston, Ont. Plans, etc., may be obtained on application at the office of Messrs. Power & Son, architects, Kingston, Ont., and at the office of R. C. Desrochers, secretary, Department of Public Works, Ottawa.

Ottawa, Ont.—Tenders will be received until March 11th, 1912, for the construction of two 150 cubic yards capacity steel hopper scows. Plans, etc., can be obtained at the offices of J. G. Sing, Esq., District Engineer, Toronto; J. L. Michaud, Esq., District Engineer, Merchants Bank Building, Montreal; G. G. Scovil, Esq., Superintendent of dredges, St. John, N.B.; and G. M. Graham, Superintendent of dredges, New Glasgow, N.S. R. C. Desrochers, Secretary, Department of Public Works, Ottawa.

Ottawa, Ont.—Tenders for the construction of a Dormitory, Royal Military College, Kingston, Ont., will be received

until March 6th, 1912. Plans, etc., may be obtained at the office of Messrs. Power and Son, architects, Kingston, Ont., and at the office of R. C. Desrochers, Secretary, Department of Public Works, Ottawa.

St. Andrews, N.B.—Tenders will be received by D. C. Rollins, secretary to School Board, St. Andrews, until noon March 11th, 1912, for the erection and furnishing of a school building in that town.

St. Catharines, Ont.—The city council of the city of St. Catharines invite tenders for about 200 cu. yds. of 2-inch crushed stone in carload lots, as required, f.o.b. St. Catharines. Tenders to be in not later than February 28th, 1912. R. D. Brown, City Engineer, St. Catharines. (See advt. in Can. Eng.)

St. Catharines, Ont.—Tenders will be received by the architect until March 12th, 1912, for the erection and completion of Holy Trinity Church, Welland, Ont. A. E. Nicholson, architect, 46 Queen St., St. Catharines, Ont.

Toronto, Ont.—Tenders will be received until Feb. 27th, 1912, for (1) mason work, etc.; (2) painting and glazing in connection with the new Police Station on Claremont Street. Plans, etc., at the office of the City Architect, Toronto. G. R. Geary (Mayor), Chairman Board of Control, City Hall, Toronto.

Toronto, Ont.—A recommendation has been passed by the Works Committee that a new concrete bridge be built over the Don River at Gerrard Street, costing $200,000.

Toronto, Ont.—Tenders will be received until March 12th, 1912, for the construction of a storm overflow sewer, Barton Avenue, section No. 2. Specifications at the office of the City Engineer, Toronto. G. R. Geary (Mayor), Chairman Board of Control, City Hall, Toronto. (See advt. in Can. Eng.)

Vernon, B.C.—Tenders will be received until March 11th, 1912, for the construction of vitrified pipe sewers. Plans and specifications, with form of tender, may be obtained at the office of the City Engineer, City Hall. D. G. Tate, City Clerk, City Hall, Vernon, B.C.

Westmount, Que.—Tenders will be received until March 11th, 1912, for the construction of the following works: A, contract No. 13, intercepting sewer, Western Avenue. B, contract No. 12, paving of Western Avenue. Drawings, etc., at the office of Archibald Currie, C.E., City Surveyor, Westmount. (See advt. in Can. Eng.)

Winnipeg, Man.—Tenders will be received until February 26th, 1912, for the supply of labor and material required for the erection of fender for the Redwood Bridge. Plans, specifications, etc., may be obtained at the office of the City Engineer, 223 James Avenue. M. Peterson, Secretary Board of Control Office, Winnipeg.

Winnipeg, Man.—Tenders will be received by the Chairman of the Board of Control until March 7th, 1912, for supply of five 36-inch and three 20-inch gate valves. Specifications and form of tender may be obtained at the office of the City Engineer, 223 James Avenue. M. Peterson, Secretary Board of Control Office, Winnipeg.

Winnipeg, Man.—Tenders will be received until March 1st, 1912, for the erection of an office building in the City of Edmonton, Alta., for the Canadian Pacific Railway Company. Plans and specifications and steel diagrams for purpose of tendering can be obtained at the office of William Wallace Blair, architect, 400 Nanton Building, Winnipeg.

CONTRACTS AWARDED.

Acton, Ont.—Mr. Geo. H. Tod, Canadian representative of Thos. Piggott & Co., Birmingham, has sold to the plant of the Beardmore Belting Company, a Piggott tank of 35,000 gallons capacity.

Calgary, Alta.—The contracts for digging the trench in which the big steel main for the Canada Western Natural Gas, Heat, Light and Power Company, from Bow Island to Calgary, will be laid, a distance of 170 miles, has been awarded in two sections to W. F. Cochrane, of Pittsburg, Pa., and J. Driscoll, of Indianapolis. The cost will be $350,000.

Calgary, Alta.—The City Commissioners have awarded the tender for the construction of the bridge over the Bow River to the C.P.R. Carshop District, to the Algoma Bridge Company, whose tender amounted to $64,300. Among those who submitted tenders for the erection of this bridge were the following firms: Cleveland Bridge Company, Canada Foundry Company, Dominion Bridge Company, Canadian Fairbanks, and G. Webster.

Haliburton, Ont.—The two bridges over the Burnt River, one 100 ft. clear span, steel bridge, the other 50 ft. clear span, reinforced concrete truss bridge, are being built by day labor under the engineer's supervision, except the steel, the contract for which has been awarded to the Dickson Bridge Works Co. at $4,185.

Ottawa, Ont.—The Department of Railways has paid Mr. W. B. Russell, the contractor for the Newmarket Canal, one thousand dollars as compensation for the cancellation of the contract for finishing the canal. Mr. Russell, in addition, receives the contract for rebuilding all the bridges over the canal, and repairing the highways demolished by construction work. He is to receive fifteen per cent. above the cost of such work. The engineers' report on the canal will show that over eighty per cent. of the work has been done, and that the amount required to complete the canal would be about $200,000.

Port Alberni, B.C.—First class 200-room hotel; Messrs. George C. Mesher & Company, architects and builders; Mr. A. E. Waterhouse, proprietor.

Quebec, Que.—Messrs. J. H. Gigorac & Company have received the contract for the Bascule Steel Bridge over St. Charles River. Estimated cost, $145,010. City Engineer, W. D. Baillairge.

St. Catharines, Ont.—Messrs. L. O'Connor and L. Binns, of Johnston & Jenkins, of New York, have the contract of installing the steam and machine heating plant in the new factory building on Vine Street for Canadian Yale Towne, Ltd.

Victoria, B.C.—The contract for the construction of the Hibben Block on Government Street, a modern fire-proof brick and concrete structure with marble facings and linings in the corridors, heavy stones, cornices, and carved capitals, has been awarded to the Westholme Lumber Company of this city. The contract price is $88,000. Other tenderers for the work included Messrs. Luney Bros., and Thomas Catterall.

West Toronto, Ont.—Messrs. Wells & Gray, Ltd., Confederation Life Building, have been awarded the contract to erect a cold storage warehouse for the Swift Canadian Company.

RAILWAYS—STEAM AND ELECTRIC.

Berlin, Ont.—The directors of the Berlin and Bridgeport Street Railway will make application to the Provincial Government for powers to extend the line to Elora, Ont. W. H. Breithaupt is president of this company.

Brandon, Man.—The municipal council intend to grant the street car franchise to Mr. J. D. McGregor. Terms will be arranged at an early date.

Hamilton, Ont.—City Engineer Macallum will prepare a map showing proposed extensions of the civic car lines.

Montreal, P.Q.—The municipal council are making application to the legislature for power to construct an underground railway.

Toronto, Ont.—The Toronto Suburban Railway Company intend to petition the Provincial Government for powers to construct a line of railway from a point on its Toronto-Hamilton line in Toronto Township, Peel County, to Brampton, and thence easterly and southerly back to Davenport.

LIGHT, HEAT AND POWER.

Lindsay, Ont.—The Seymour Power Company, according to report, will erect a sub-station in connection with the company's transmission line from Peterboro to Lindsay. It is understood that the Seymour Company will bring the power from Peterboro at 12,000 volts, with a step down at the sub to 4,000 volts. Mr. J. S. Denik, of Trenton, is the company's official in charge of the work at this point.

Peterborough, Ont.—The municipality of Peterborough seeks authority from the Provincial Government to expropriate the plant and property of the Otonabee Power and Light Company.

Tarvia

Preserves Roads
Prevents Dust

Lancaster St., Berlin, Ont. Constructed with Tarvia X Modern Pavement

Meets Modern Road Requirements

TARVIA is a powerful binder for the surfaces and foundations of macadam roads. It fills the voids and locks the stone in a tough, durable, plastic matrix.

A Tarviated surface looks like sheet asphalt and is equally dustless and clean. It sheds water readily and is dry immediately after the rain, so that pedestrians are not inconvenienced. The surface never gets muddy or dusty.

On account of the Tarvia matrix, these roads will bear heavier automobile traffic than plain macadam because the surface yields instead of pulverizing under the strains. The Tarvia matrix prevents internal movement and grinding.

The plasticity of the Tarvia also makes these roads very quiet. Horses' hoofs make almost no sound on a Tarviated road. Tarvia is waterproof, and Tarviated roads, therefore, are protected against damage from torrents on grades.

Tarvia has no odor except when being applied. After it hardens, it has no injurious effect on shoes, clothing or vehicles. The cost of using Tarvia is not a factor for consideration, because it has been repeatedly demonstrated that it is cheaper to maintain a dustless road with Tarvia than a dusty one without it. Maintenance economies more than balance the additional cost.

Booklets on request. Address our nearest office.

The Paterson Manufacturing Co., Limited
Montreal Toronto Winnipeg Vancouver

The Carritte-Paterson Manufacturing Co., Limited
St. John, N.B. Halifax, N.S.

St. Stephen, N.B.—This municipality has taken an option on the entire output of the Eel River Heat, Light and Power Company. Mr. R. G. Lee is secretary of this company. The proposed plant will have a capaity of about 3,000 horsepower.

GARBAGE, SEWAGE AND WATER.

Berlin, Ont.—The municipal Water Commission will reduce the rate to consumers.

Moose Jaw, Sask.—The municipal council will erect a large water tank at Sandy Creek. It is to have a capacity of 75,000 gallons.

Fort William, Ont.—City Engineer Wilson has stated that it will be necessary to construct a duplicate of the water supply pipe from Loch Lomond to the reservoir if the Canadian Pacific Railway continue to draw their supply from the civic mains.

North Toronto, Ont.—The municipality will construct a 6-inch water main on Roman Avenue. Mr. E. A. James, town engineer.

Port Stanley, Ont.—The plans for a new waterworks, prepared by J. Bell & Son, St. Thomas, have been approved by the municipal council. A by-law will be prepared and voted upon by the ratepayers. The cost is estimated at $22,000, and the plans include 21 hydrants, 600 feet of fire hose and an electric pump. Messrs. Gummond and Finlay, councilmen.

South Vancouver, B.C.—This section of Vancouver city has made an appeal to the council for a better water supply. Mr. Fellowes, City Engineer.

Toronto, Ont.—The estimates for the Board of Works include $145,200 for sewers and $7,458 for reservoir expenses. Mr. Fellowes, Engineer of Waterworks.

BUILDINGS AND INDUSTRIAL WORKS.

Berlin, Ont.—The Park Commission of this municipality will erect a $20,000 concrete grand stand. Work is to commence at an early date. Mr. H. Johnston, City Engineer.

Calgary, Alta.—Mr. J. W. Scott, of Winnipeg, Man., is taking steps to establish a tar and creosote factory at this point.

Galt, Ont.—The Galt Knitting Company, Ltd., are planning an addition to their premises. The addition will be 35 x 50, of sand lime brick.

Guelph, Ont.—Mayor Thorp has expressed his opinion to the effect that he is in favor of improving the fire fighting system and erecting a new fire station.

Highgate, Ont.—The British Canadian Canning Co. are taking the preliminary steps toward the erection of a cannery at this point.

Kingston, Ont.—The Buffalo Ontario Smelting Co. intend to erect a plant on Cataraqui Bay. W. W. Sands, M.D., municipal clerk.

Merritton, Ont.—A branch factory of the Presto Light Company of Indianapolis, Ind., will be established in this village. The building is to cost about $4,000.

Montreal, P.Q.—The Belgo-Canadian Company, manufacturers of steel, have been making enquiries relative to the establishment of a plant in the Maisonneuve district. A committee of the city council will report.

Moose Jaw, Sask.—The new building of the "Robin Hood Flour Mills" is to be a seven-story frame structure, metal clad, 112 x 54 feet. The elevator will be concrete built, consisting of from 12 to 15 concrete tanks, having a combined capacity of 250,000 bushels. A warehouse will be built, measuring 160 feet by 64 feet, consisting of four stories. Adjacent to this an oat mill will be built, a seven-story building measuring 96 feet by 64 feet, with a capacity of 500 barrels per day. Contracts will be let out for these buildings in a few weeks and construction will be rushed at full speed. Mr. C. E. W. Austin is interested.

Owen Sound, Ont.—The Board of Education will erect a $25,000 school building. Tenders will be called for at an early date.

Regina, Sask. — Messrs. Storey and Van Egmund are preparing plans for a hotel at Findlater on the C.N.R. north line.

Regina, Sask.—A large ice house and other buildings will be moved from their present position adjoining the Canadian Pacific Railway lines. Mr. S. Cox has the contract for the removal.

Saskatoon, Sask.—The Salvation Army intend to erect a $25,000 Citadel in this city. J. W. McBain, of Winnipeg, may build the structure. The Salvation Army also intend to erect buildings at Edmonton, Strathcona, Regina, and Moose Jaw. No definite plans for these structures have been completed.

Saskatoon, Sask. — Mr. David Webster, architect, has prepared plans for a $75,000 office building to be erected on 3rd Avenue and a $20,000 apartment block for Nutana. The owner of the apartment block is Mr. S. K. Clotworthy. At the present time, Mr. Webster is preparing sketches for three new schools for the city and he has also the work of preparing plans for two schools in outside places.

St. Catharines, Ont.—The plans for a structural steel erecting shop of the Canadian Crocker-Wheeler Co., together with plans for a fireproof japanning and impregnating building, have been prepared by E. D. Pitt, Niagara Falls, Ont., Engineer and Architect.

St. John, N.B.—Messrs. C. H. Peters' Sons, tanners, are contemplating enlarging their plant. They may erect a new structure and install new equipment.

Toronto, Ont.—New buildings for the exhibition grounds to be erected this year are to cost $55,000. Dr. Orr, exhibition manager.

Vancouver, B.C.—Messrs. Sullivan & Considine will construct a ten-story building for office and theatrical purposes. $350,000 will be spent on the structure.

Victoria, B.C.—Mr. W. Ridgway-Wilson is the architect for a new church to be erected in this city. The materials will be brick and terra-cotta.

Whitby, Ont.—The Ontario Government is considering the erection of an asylum near this town. The first portion to be constructed will accommodate 1,200 patients.

Winnipeg, Man.—The Manitoba Bridge & Iron Works intend to erect a new plant. Mr. T. R. Deacon is the president of this company.

Winnipeg, Man.—Messrs. J. W. & H. P. Frid, general contractors, have transferred their interests to the firm of The Frid-Lewis Company, Ltd.; capital, $150,000. The new firm has been organized for the purpose of entering the contracting and engineering business. Mr. F. C. Lewis will be in charge of the engineering department.

Woodstock, Ont.—There is some movement in this municipality to prepare a by-law calling for the erection of a $75,000 city hall. Ald. John Butler is interested in the project.

BRIDGES, ROADS AND PAVEMENTS.

New Westminster, B.C.—The municipal council have placed an order with Mussens Ltd., Montreal, for a 12-ton Rushton Proctor road roller with three tyne scarifier.

North Toronto, Ont.—The municipal council intend to have $6,300 worth of concrete walk laid in the near future. Mr. E. A. James, Engineer.

North Toronto, Ont.—This municipality will construct a $2,500 concrete bridge on Albertus Avenue. Mr. E. A. James, town engineer.

Oxford County, Ont.—Oxford County will seek powers from the Provincial Government to issue debentures to raise $133,467 for a county road system. Mr. N. E. Birtch, county clerk.

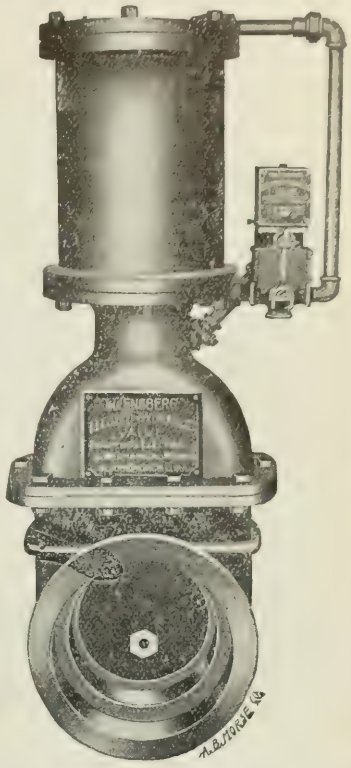
Stettler, Alta.—The Stettler district agricultural society intend making application for $10,000 for provincial road improvements. The application will be made to the department of Public Works.

Toronto, Ont.—The estimates of the Board of Works include $277,015 for new bridges, $51,752 for concrete sidewalks and $36,250 for street grading.

Toronto, Ont.—City Engineer Rust has recommended that a new concrete bridge be erected over the Don River at Gerrard Street. The estimated cost of the work is placed at $200,000.

Toronto, Ont.—Pavements on the exhibition grounds to be laid this year will cost $18,000. Dr. Orr, exhibition manager.

The "ENGBERG" VALVE



A VALUABLE ADJUNCT

No waterworks system, having a standpipe or reservoir, can afford to be without this valve, a most valuable adjunct, increasing the effectiveness when fire pressure is desired and permitting a reduction in the cost of maintaining ordinary domestic pressure.

We are sole agents for Canada.

Read what a Fire Chief says—

"Your electric shut-off valve has been a great assistance to us in putting out fires, as it enables the engineer at the pumping station to increase the water pressure in an instant, whereas it took from twenty to thirty minutes to change before the same was put in; a man having to go to the stand pipe and close the valve and also telephone to the engineer notifying him of the same. Now it is all done at the pumping station, and by the time we are able to make connections we have direct pressure. Any chief knows what it means to try and fight fire without sufficient water pressure."

FIRES.

Camrose, Alta.—A fire at the Round Hill Collieries caused $3,000 damage.

Montreal, P.Q.—The establishment of F. Thompson & Company, manufacturers of electric motors, was damaged by fire to the extent of $12,000.

Sherbrooke, Que.—$30,000 damage was caused by fire to a business block owned by Ald. D. McManamy. Commercial offices and stores occupied the block.

CURRENT NEWS.

Newcastle, N.B.—The dredging plant of A. & R. Loggie Company has been purchased, according to report, for $250,000.

Ottawa, Ont.—Civic supplies for 1912 will be supplied under the following prices:—Brick, the Peerless Brick Company, at $8.70 per 1,000. Castings, Messrs. Thos. Lawson & Sons, at $2.50 per 100 lbs. Sand, the Rideau Canal Supply Company, at $1.10 per cubic yard. Nepean stone setts, Saml. Bilsky, at $52.75 per 1,000 for ordinary setts, and $62.75 per 1,000 for track allowance blocks. Cement, H. Dupuis & Sons, at 50½c. per 100 lbs. Street sweepers' brooms, W. G. Charleson, at $9 per dozen. Vitrified clay pipe, T. S. Kirby Co., for Garthcraig. Scotch pipe at 54½ per cent. discount on price list. Asphalt, Canadian Mineral Rubber Co., Pioneer refined asphalt, $24.04 per ton; Elder Ebano Asphalt Co., Ebano Mexican asphalt, $25.60 per ton; the Barber Asphalt Paving Co., for Trinidad Pitch Lake asphalt, $27.25 per ton.

Toronto, Ont.—The revised building by-law will call for a more rigid inspection of concrete, and the construction schedule of concrete will be a little lighter.

TRADE ENQUIRIES.

The following were among the inquiries relating to Canadian trade received at the office of the High Commissioner for Canada, 17 Victoria Street, London, S.W., during the week ended January 29th, 1912. Fuller information may be obtained by communicating with the Department of Trade and Commerce, Ottawa.

A Yorkshire manufacturer of copper cylinders, washing coppers, towel rails, copper boilers, copper coils, furnace pans, tanks, etc., desires to appoint an energetic and reliable representative at Winnipeg.

A London firm are open to handle minerals or agricultural produce from Canada, either on commission or purchase basis.

A London firm having connections with Spanish shippers of fruit pulp are open to hear from Canadian jam manufacturers or other importers in the Dominion.

Inquiry is made by a correspondent in Italy for the names of reliable parties in Canada willing to act as agents for the sale of pure olive oil.

A Winnipeg firm are anxious to get into touch immediately with a United Kingdom potato merchant in a position to ship large supplies for the Canadian market.

A New Brunswick correspondent desires to dispose of a considerable quantity of sawdust and invites inquiries from United Kingdom importers.

A correspondent at Prince Rupert, B.C. (the terminus of the Grand Trunk Pacific Railway), is open to take up agencies for tool steel, belting, mine and mill supplies, piping (iron and clay), marine motors, concrete machinery, contractors' supplies, etc.

A Nova Scotia correspondent who is beginning the manufacture of men's and boys' braces, is desirous of being placed in correspondence with United Kingdom makers of buckles, webbing and leather trimmings.

A Nova Scotian, at present in Birmingham, is open to purchase supplies of cocoa and other fibre for brush making; also mop stick and broom handles.

An important Western Canadian firm of manufacturers' agents are desirous of securing United Kingdom agencies for mining machinery, tools and supplies of every description; gas engines; fire and steam hose for railways, etc.; briquette machinery; farm machinery; traction engines; fire extinguishers; chains; cotton waste; vacuum cleaners; automobile tires; gunpowder; firebricks; tiles; glass; and many other lines. A representative is now visiting Great Britain.

A Vancouver correspondent at present in London, desires agencies for dry goods, athletic and sporting goods.

A correspondent in the province of Quebec is desirous of getting into touch with the inventor of the English viscose-Stearn system of artificial silk; also with manufacturers of machinery for manufacturing this article.

A Vancouver correspondent wishes to get into communication with United Kingdom manufacturers requiring representation in British Columbia.

An Ottawa firm of mica miners desire to get into touch with United Kingdom buyers of ground and thumb-trimmed mica, in which they specialize.

From the Branch for City Trade Inquiries, 73 Basinghall Street, E.C.:

A manufacturing company in Sweden invite quotations from Canadian producers of maple rollers suitable for mangles and wringers.

A Glasgow firm wish to make arrangements for obtaining regular supplies of Canadian corundum, and would also be glad to hear from producers of alabastine, magnesite, manganese and asbestos.

The Swedish manufacturers of an incandescent oil lamp wish to arrange for its sale in Canada.

An English firm manufacturing hosiery yarns, Egyptian and super American cop, cone, cheese or hank, wish to get into correspondence with Canadian buyers.

A London business man who spends several months each year in visiting the fruit and grain growing districts of Ontario, Western Canada and British Columbia, would be glad to hear from makers of artificial manure, fertilizers, insecticides, hop and fruit washes, etc., who wish to have their specialties introduced.

A British Columbia firm which regularly covers the whole of Canada in the interests of a textile manufacturer, and claims a good connection, seeks the representation of an up-to-date Yorkshire manufacturer of low and medium priced fancy worsteds and serges.

A London business man who pays an annual visit to Canada and has many years' experience of Canadian trade, is open to represent manufacturers of stationery and fancy leather goods seeking business in Quebec, Ontario and the Northwest. References supplied.

A manufacturers' agent in Victoria, who covers British Columbia and Western Canada, is open to represent a few United Kingdom manufacturers, provided that he is granted the sole agency for the territory named.

The following were among the inquiries relating to Canadian trade received at the office of the High Commissioner for Canada, 17 Victoria Street, London, S.W., during the week ended February 5th, 1912. Fuller information may be obtained by communicating with the Department of Trade and Commerce, Ottawa.

A Scottish correspondent desires to arrange for the sale of the Canadian patent rights in a system of cold-resisting and heat-conserving applicable to hot pipes (air, steam or water), etc.

A Glasgow correspondent dealing in iron and steel goods of various kinds, desires to do Canadian business.

A North of England firm of veterinary preparation manufacturers desire to appoint buying agents having connections among horse owners in Canada.

A Coventry manufacturer of motor car radiators, lubricators, silencers, bonnets, tanks, wings and other auto parts, desire to introduce their goods into Canada.

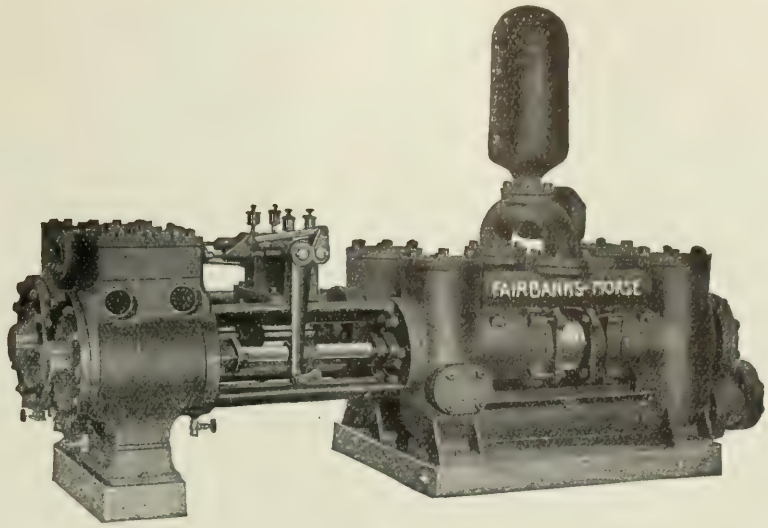
A Scottish firm are open to hear from Canadian importers of bottled castor oil.

A New Brunswick company manufacturing maple meat skewers desire to get into touch with London Indent Merchants in a position to arrange for the sale of such goods in Argentina, Australasia and South Africa.

A correspondent who is shortly returning to Canada wishes to secure the representation of United Kingdom firms open to do business in the Northwest or in British Columbia.

A Montreal firm of importers of English and French pharmaceutical products is open to take up United Kingdom agencies.

A Montreal firm make inquiry for the names of high-class United Kingdom manufacturers of travelling rugs suitable for automobile use.



PUMPS

The superior excellence and splendid results shown by

"FAIRBANKS-MORSE"

pumping machinery are largely due to the fact that for many years we have manufactured Hydraulic Machinery of all descriptions. We are therefore able to build pumps which are properly designed and adapted to every-day use. This is of the greatest importance in a first-class pump, for the usefulness of an engine may be lost if the pumping machine is badly designed.

You will get all these important features when you purchase a "FAIRBANKS-MORSE" pump.

Let us solve your pump problems.

THE CANADIAN FAIRBANKS-MORSE CO. Limited

Fairbanks Standard Scales — Fairbanks-Morse Gas Engines.
Safes and Vaults.

Montreal Toronto Winnipeg Vancouver Calgary St. John, N.B. Saskatoon Ottawa

From the Branch for City Trade Inquiries, 73 Basinghall Street, E.C.:

A London company ask to be placed in touch with Canadian manufacturers of Kraft brown, news printing, and glazed colored papers, who can fill orders for shipment to Australia and New Zealand.

A Welsh company manufacturing patent solid woven machine belting, wish to get into touch with Canadian engineering and mill furnishing supply firms who can introduce this line.

A furniture manufacturing firm in Sydney, New South Wales, wish to obtain an agency for Canadian wooden chairs, upon a commission basis, and would like to receive catalogues from Canadian manufacturers interested.

A Glasgow firm ask to be placed in touch with Canadian producers of ochres, and are also interested in Kaolin.

A New Brunswick company manufacturing staves and headings would be glad to receive inquiries from United Kingdom importers. They can also supply large quantities of box shooks.

A New Brunswick company manufacturing spruce and white pine of all dimensions, also cedar railway sleepers and pine and cedar laths, would be glad to quote for all these lines.

EQUIPMENT FOR RUSSIA.

The management of this paper have an enquiry for the names of engineering firms prepared to tender for the supply of the following for Russia:—

(a) Electric furnace for scrap iron, 16-25 tons per diem.

(b) A rolling mill of smallest possible size (round) up to 3-inch diameter. (b) Rectangular 1⅞-inch by 1¼-inch and 1½-inch by 1⅝-inch.

(c) Bending and electric welding machines for chains from ⅛-inch to ½-inch.

(d) Stamp and forging machines for scythes, sickles and horse shoes.

(e) Lamps for giving about 200 candle-power from crude naphtha.

(f) Machine lathes for turning pick and axe handles (taper).

(g) Machines for making long boots of thick felt and similar materials.

Address in first instance to Box 100, Canadian Engineer, 62 Church Street, Toronto.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA.

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from The Canadian Engineer for small fee.

15917—February 8—Extending until June 1, 1912, time for installation of interlocking plant by C.N.R. to cross C.P.R. near Forward, Sask.

15918—February 8—Approving location of C.N.R. station at Cylde, Alta.

15919—February 8—Authorizing C.P.R. to divert certain streams by means of 8-foot concrete culvert at mileage 110.1 on Cascade S.D., B.C. Division.

15920-21—February 8—Authorizing G.T.R. to reconstruct bridge over Mud River at mile post 4.87, Rockland Branch, and at mile post 8.06, Hawkesbury Branch, Ontario.

15922—February 8—Relieving C.P.R. from erecting fence, gates and cattle guards on B.C. Division, Laggan S.D.

15923—February 6—Authorizing village of Luseland, Sask., to construct highway across tracks of C.P.R. at mileage 15.95.

15924—February 10—Authorizing C.P.R. to use and operate five bridges on its Havelock & Toronto S.D., Ontario Division.

15925—February 10—Authorizing Pere Marquette Ry. to remove derails and signals from track connection C.P.R., and re-arrange interlocking in tower so that towerman can give freight trains a through route to and from the Windsor yard of the C.P.R. (Pere Marquette operating Lake E. & Detroit Ry.)

15926—February 5—Approving overhead crossing of Lake Erie & Northern Ry. over T.H. & B. and M.C.R. at village of Waterford, Ont.

15927—February 6—Authorizing Lachine, Jacques Cartier & Maisonneuve Ry. (G.T.R.) to cross tracks of C.P.R. in city of Montreal, at entrance to Angus and near Nolan St., and to take lands of C.P.R.. C.P.R. to re-arrange its spurs into Angus Shops, compensation to be fixed by agreement, etc.

15928—February 12—Rescinding Order No. 15254, October 11, 1911, re branch lines near Jex St., Brantford, Ont. G.T.R.

15929—February 12—Authorizing C.P.R. to cross with its Pheasant Hills Branch twenty-five highways, mileage 296.11 to 317.15, Saskatchewan.

15930—February 10—Authorizing C.N.R. to cross with its Calgary Southerly Line twenty highways in Alberta.

15931—February 13—Approving location of Kettle Valley Ry. from mileage 28 to 52 from Hope, B.C.

15932—February 12—Authorizing C.P.R. to open for carriage of traffic portion of railway near Steel Siding, District of Thunder Bay, mileage 92 to 95, a distance of about three miles.

15933—February 13—Approving location of Algoma Central & H.B. Ry. Co.'s station at Tagona, Ont.

15934-35—February 12—Authorizing C.P.R. to construct spurs for Canadian Lumber Yards, Ltd., at Winnipeg, Man., and into premises of Crow's Nest Pass Lumber Co., Ltd., near Wardner, B.C.

15936—February 12—Authorizing C.N.O. Ry. to cross public road between Cons. 1 and 2, on Lot 8, Twp. of South Crosby, County of Leeds, Ont.

15937—February 12—Refusing application of Canadian Fraternal Association for an Order prohibiting G.T.R., G.T.P., C.N.R. and M.C.R. from collecting 25 cents from delegates attending conventions for viseing or certifying certificates of delegates.

15938—February 6—Authorizing Lachine, Jacques Cartier & Maisonneuve Ry. (G.T.R.) to cross Rachael, Hogan, Bercy and Sherbrooke Sts., in Montreal, by overhead crossings.

15939—February 12—Authorizing C.N.O. Ry. to cross eleven highways in Twp. of Markham, County of York, mileage 14.9 to 25.69 northerly from new Union Station site, Toronto, Ont.

15940—February 13—Authorizing C.N.O. Ry. to open for carriage of freight its line from Belleville to Deseronto, a distance of 16½ miles.

15941—February 3—Authorizing C.P.R. (B.C. Southern Ry.) to construct tracks of its spur from Waldo Branch to Baynes Lake across G.N. Ry. (Gateway to Fernie) at mileage 1.4 in Lot 1899, E.K.D. In Province of British Columbia semaphore protection.

15942—February 13—Authorizing N.Y.C. & H.R.R. to reconstruct bridge No. A-38 on Adirondack Division, 0.3 miles north of Athelstan.

15943—February 12—Approving location of Edmonton, Dunvegan & B.C. Ry. through Twps. 53-56, Ranges 24-26, West 4th, Alberta.

15944—February 3—15945—February 10—15946—February 3—Authorizing C.P.R. to construct industrial spur in town of Swift Current, Sask., with three sub spurs; and spur for Frontenac Breweries, Ltd., at Mile End, Que. (Montreal), and spur for D. D. Wood, city of Winnipeg, Man.

Tenders Called For

(Continued on Pages 68, 70, and 72).

CITY OF MOOSE JAW, SASK.

Sealed tenders will be received by the undersigned up to noon of Monday, March 18th, 1912, for supplying and erecting a reinforced concrete reservoir of two millions (2,000,000) gallons capacity.

Specifications and all information may be obtained from the undersigned or at the office of Walter J. Francis & Co., Consulting Engineers, Montreal.

The right is reserved to accept or reject any or all tenders.

By order of the City Commissioners.

E. B. BONNELL,
City Clerk.

Moose Jaw, Sask., February 22, 1912.

CITY OF MOOSE JAW, SASK.

Sealed tenders will be received by the undersigned up to noon of Monday, March 18th, 1912, for supplying and erecting four centrifugal pumps, two motors, wiring, switchboard and accessories.

Specifications and all information may be obtained from the undersigned or at the office of Walter J. Francis & Co., Consulting Engineers, Montreal.

The right is reserved to accept or reject any or all tenders.

By order of the City Commissioners.

E. B. BONNELL,
City Clerk.

Moose Jaw, Sask., February 22, 1912.

CITY OF MOOSE JAW, SASK.

Sealed tenders will be received by the undersigned up to noon of Monday, March 18th, 1912, for supplying various valves and fittings for waterworks installation.

Specifications and all information may be obtained from the undersigned or at the office of Walter J. Francis & Co., Consulting Engineers, Montreal.

An Engineering Weekly

PNEUMATIC CAISSONS AT FORT WILLIAM.

By A. GILLIES, B.A.Sc.

In the construction of the foundations for the Kaministiquia River Bridge for the C.P.R. at Fort William, it was found necessary to use pneumatic caissons, in getting down to bed rock, for the two main piers.

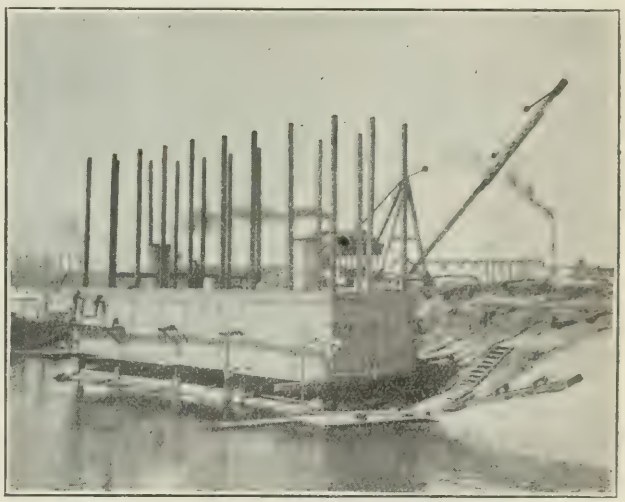
A. C. Stewart & Company have recently finished their contract for the foundation work, which proved to be a rather difficult proposition. The soundings showed bed rock at an elevation of from thirty to forty-five feet below water level, and the central piers were required to have a level bearing on solid rock.

As soon as the pneumatic caisson method was decided upon, an up-to-date air plant was at once ordered. This consisted of two Rand, Class C, air compressors, having steam cylinders 12-inch by 18-inch stroke and air cylinders 15-inch by 18-inch stroke, 515 cu. ft. each per minute at 140 R.P.M.; a 48-inch by 12 feet vertical air receiver; a water-tube aftercooler; a 50 horse-power feed-water heater; duplex

1. Caisson Under Construction.

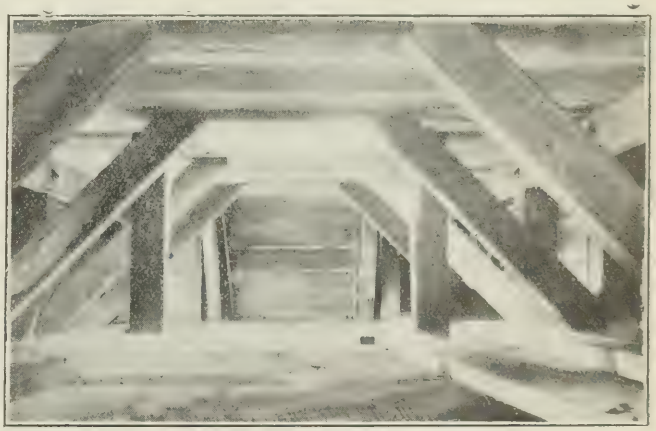
feed pumps; two duplex water supply pumps; one high pressure air compressor, steam and air cylinders 6-inch by 8-inch stroke, capacity 50 cu. ft. per minute at 195 R.P.M. with air receiver, pneumatic wood-borers and drift bolt drivers; and two 50 horse-power locomotive type boilers.

The caissons were 18 by 80 feet and built of British Columbia fir. (Fig. 1.) The walls were of 12-inch by 12-inch timber, caulked both inside and out, and planked outside with 3-inch by 12-inch vertical plank, which was also caulked. The inside posts and struts were of 12-inch by 12-inch, and the braces of 8-inch by 10-inch timber, placed at 6 feet 3-inch centres, and strengthened by 1-inch steel strut and roof rods, the roof consisted of two layers of 12-inch by 12-inch timber transverse and longitudinal; ¾-inch by 26-inch drift bolts at 36-inch centres were used in the heavy timber and ⅜-inch by 7-inch ship spikes in the plank. The working chamber was 8 feet deep and divided in the centre by a timber bulkhead of 12-inch by 12-inch timber, having 3 ft. by 4 ft. man-hole for free passage between chambers. One man-lock three feet in diameter was used and two



2. Caisson Ready to Launch.

material locks 4½ feet in diameter, of the Moon type, allowing the free passage of the bucket cable through the top doors for use in excavation of rock, etc. The working chamber of the caisson was built of 60,500 ft. B.M. of timber and 10,300 lbs. of bolts, ship spikes, etc., and had 21,800



3. Inside View of Caisson.

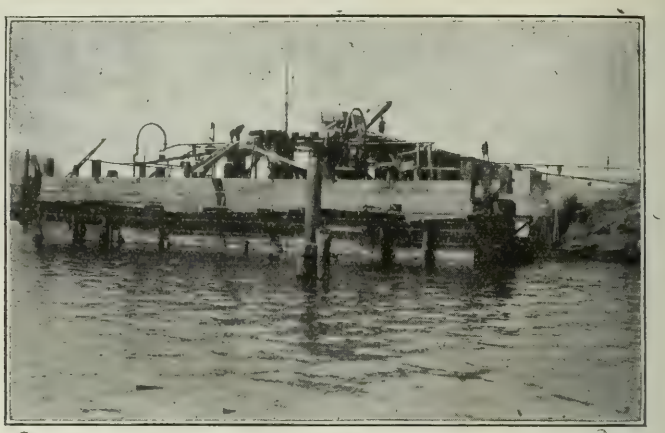
feet of caulking. The caisson was built on a skidway having a slope of 1:5. There were five skid timbers, each skid being supported by eight piles driven to hard-pan. When

the caisson was ready to launch, the supporting timbers were, one at a time, lowered down to the skid timbers which had been well greased, and the caisson allowed to slide out in a horizontal position. Before launching, the first sections of the man-lock and two material locks were bolted into position, also all pipe connections through the deck and inside fittings placed. These consisted of two 5-inch pipes with flap valves for the air; one 3-inch pipe for water connections, with valves, hose, etc., for three jets; three 4-inch pipes, with valves, hose, etc., for blow-off pipes; one connection for high pressure air; two whistle pipes; and electric lighting connections.

4. Launching Caisson.

After launching the caisson, it was towed into position and secured there by means of cables and piles. There is very little current in the river at this place, so little difficulty was met in keeping the caisson in position.

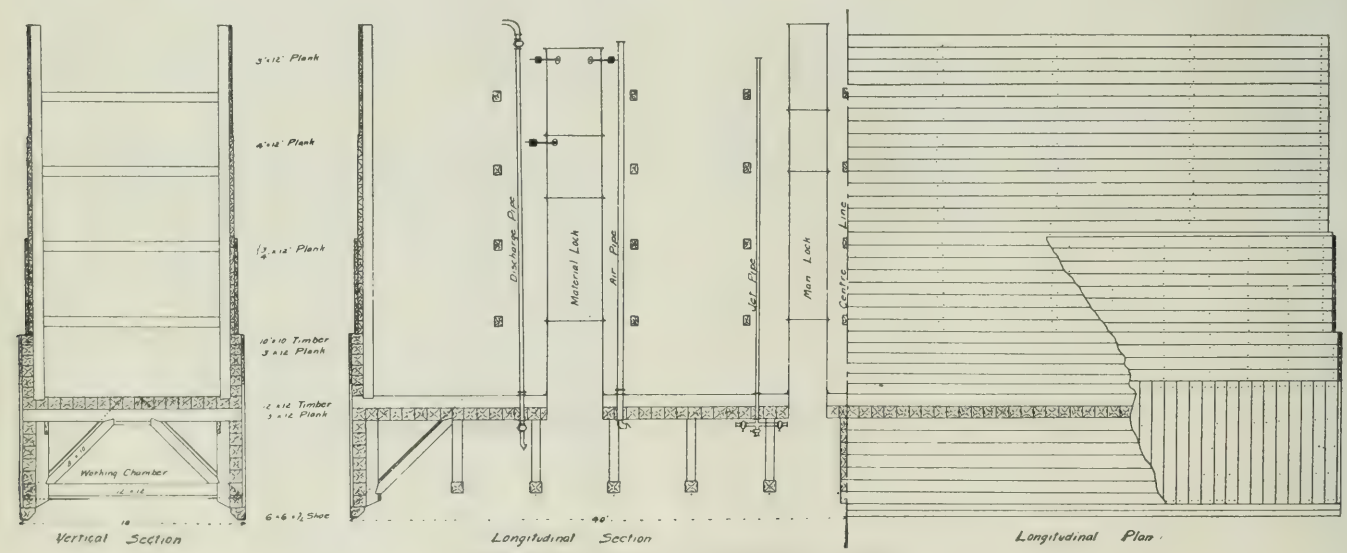
The caisson was then sunk by placing concrete on the deck, forms having first been built around the air lock shafts and piping so that they could be recovered; and the coffer dam kept well above the water level. When the shoe of the caisson was bedded in the river bottom, the air pipes were connected with the compressors and the caisson filled with compressed air. On starting operations in No. 1 caisson, the shoe was 20 feet below water level and nine pounds pressure was used. The water inside the caisson being driven out under the shoe, the air men, or "sand hogs" as they are called, entered the caisson through the man-lock; and excavation began. Three eight-hour shifts of about twenty men each were worked continuously. The air pressure and upper weight of concrete were increased as the caisson sank until, at bed rock, 38 feet down, an air pressure of 16 pounds was used. Boulders and rock were excavated in buckets through the material locks; but all clay, gravel and small stones were blown out through 4-inch pipes by the pressure within the chamber. The upper excavation was a boulder clay, the boulders ranging from small stones up to some the size of a barrel. The lower excavation was a gravelly hard-pan, also full of boulders. This had to be picked and spaded before the jets would have much effect on it, the blow-pipes were governed by 4-inch cast-iron plug-cocks which were opened



5. Sinking Caisson.

and closed as required. A ¾-inch plug-cock tapped into the pipe above this valve and left open while blowing out material, helped considerably. A 4-inch hose, 15 feet long with a 3½-inch nipple on the end, was kept with its nozzle in a pool of water formed by the jet; and the material to be excavated shoved by hand to the nozzle by the "sand hog" operating the pipe. The pressure of the air forced it up and out without the loss of very much air from the chamber.

In the hard-pan excavation, the material was taken out for from three to four feet below the shoe of the caisson but leaving a bank of material, clear around, supporting the caisson. Excavation was then suspended, and this bank was picked down to a level bench, leaving the caisson suspended by the friction on its sides. When everything was clear below the shoe, the blow-pipes were opened and the air pressure lowered three or four pounds. The weight of concrete on top was so regulated that the caisson would then



Sections and Plan of Pneumatic Caisson.

settle down on to the hard bench below the shoe. Clay was then used to "mud-up" underneath the shoe, to prevent the leakage of air; and excavation commenced again.

About 900 cubic yards of material was excavated from No. 1 caisson, including about 50 cubic yards of bed rock which had to be blasted out in one end of the caisson to get a level bearing for the pier.

When the excavation was completed, the work of concreting the caisson began. The concrete was poured on to the bottom door of the material locks and then dropped into the caisson. Wet concrete was used until the caisson was filled to within four feet of the deck. It was then sent down very dry; and benched and packed tight against the deck, leaving a narrow passage down the centre. This passage

6. Excavating Stone.

was then packed full, up to the locks and the air taken off. Six weeks was the average length of time required to excavate and concrete each caisson.

Two other caissons of the same construction were sunk for the McKellar bridge. These caissons, however, went down 45 feet and required 18 lb. pressure.

Mr. A. C. Stewart was in charge of the work; the writer was contractor's engineer; and G. N. W. Otty, B.Sc., resident engineer for the Canadian Pacific Railway.

NEW OCEAN DOCKS.

Messrs. Harland and Wolff, the famous Belfast shipbuilding firm, intend to establish ship repairing works at Liverpool.

At a meeting of the Mersey Docks and Harbor Board, it was recommended by a committee that the North dock yard at Bootle should be let to Messrs. Harland and Wolff, and the motion was adopted. The site has been taken on a sixty years' lease. It will not be necessary to construct a new dock in connection with the scheme.

Lord Pirrie, head of Harland and Wolff, is largely concerned with the White Star, American, Leyland, and Dominion lines, and with Elder Dempster and Company, Lamport and Holt, and the Pacific Steam Navigation Company, which have all been managed from Liverpool. Their tonnage aggregates over two million. The new works will employ nearly 1,000 hands.

STEAM ROLLING OF WATER-BOUND MACADAM ROADS.

General directions for the steam rolling of water-bound macadam roads are given the Road Board (Great Britain) specification No. 7. This was issued in December last, and will be of interest to all municipal and good roads engineers. We publish it in full.

1. General.—These general directions are intended for use in cases where a new surface coating is to be laid with steam-rolled water-bound macadam on any road which has a proper foundation or sub-crust of adequate thickness.

2. Trial Trenches.—Before laying the new surface the thickness of the old crust, including the foundation, should be ascertained by opening trial trenches at intervals averaging about 150 yards apart, extending from the side to the centre of the road, such trenches to be made alternately on opposite sides of the road. A careful record of the facts disclosed by these trenches should be kept, with plans and sections, for future reference.

3. If a proper foundation or sub-crust of adequate thickness does not exist, or if the road is weak at the haunches, the following steps should be taken:—

In the case of heavily trafficked roads the haunches should be strengthened and the crust thickened either with stone of any kind suitable for bottoming work, broken to a gauge of from 3 in. to 4 in., or with hard core, clinkers, or other suitable materials, according to the nature of the subsoil. In some cases, where the surface of the broken stone, after being steam-rolled, is sufficiently smooth for the purpose of traffic, it may be possible to allow the bottoming material to be used as the wearing surface of the road for a short period, not exceeding twelve months, if it is important for financial reasons to postpone for that period the laying down of the final surface coating in accordance with the other provisions contained in these general directions.

4. Total Thickness of Crust.—Even when there exists a good natural foundation, the total thickness of the road crust, including the old and the new macadam after consolidation by rolling, should not be less than 4 in. In the case of well-drained sub-soil, which cannot be materially softened by the infiltration of surface water, the total thickness, including the new consolidated surface coating as well as the sub-crust and foundations (if any), should not under ordinary circumstances be less than 5 in. In the case of fairly hard clay or other yielding sub-soils the total thickness, including foundations, should not be less than 9 in. In the case of soft wet clay or bog or marshy sub-soil, foundations of a special character may be required. (See No. 10, Appendix.)

5. Thickness of New Surface Coating.—The thickness of the new surface coating of macadam when consolidated by rolling should be from 2 in. to 3 in., according to the traffic requirements. If it is desired that the new coating should have a greater thickness than 3 in. when consolidated the stone should be applied in two coatings separately rolled.

6. Cross-fall.—The finished surface should have a cross-fall of 1 in 24, or ½ in. to the foot. If the old crust is not sufficiently thick at the crown to enable this cross-fall to be obtained when a new coating of the thickness above mentioned is super-added, the old surface should be left intact and unscarified, and the thickness of the new coating of macadam should be increased as far as may be necessary. If the crust is of ample thickness, but the cross-fall excessive, it should be reduced by scarifying the surface and removing material from the crown to the sides previous to the application of the new coating. The material so loosened by scarifying should be screened, and all material finer than ½ in. should be put on one side to be used for top dressing during rolling operations.

7. Stone and Screenings.—The road stone for the new surface coating should be stone of approved quality, broken as cubically as possible, and should contain about 70 per cent. of stone, which will pass through a 2½-in. ring, but which will not pass through a 1¾-in. ring, about 20 per cent. which will pass through a 1¾-in. ring, but which will not pass through a screen with rods ¾ in. apart. The screenings forming the residue from the above, which will be obtained by the use of the ¾ in. rod screen, should be kept separate and used as a top dressing during rolling operations.

8. Spreading.—The stone must be spread by careful men selected for their knowledge and experience of such work, as the durability and evenness of wear of the surface obtained by steam-rolled coatings greatly depends on judicious uniform spreading. The whole of the stone should be turned over in the process of spreading. Care must be taken not to allow the stone to be tipped upon the road close to the point of spreading, as this prevents a thorough turning over of the material in the act of spreading. When stones are transported by rail or by road over long distances the different sizes of stone are liable to separate themselves, and it is important that during the act of spreading they should be well mixed, so as to obviate the possibility of having larger stones on some parts of the road and smaller stones on other parts.

Note.—One ton to cover 8 to 9 square yards may be taken as an average quantity required to give a consolidated thickness of 3 in.

When stones are spread in thick coatings so that 1 ton covers less than 8 yards, there is a greater liability to unequal consolidation, inasmuch as stones are pushed in front of the roller until the roller surmounts them and thus a corrugated or wavy surface is formed.

9. Rolling.—The rolling should be carried out by a roller of a weight of about 10 tons. This must be in charge of a skilled driver who has been specially trained for the purpose. The macadam should be consolidated by starting the work at the sides and gradually working towards the centre. No water or binding should be applied until dry rolling has been carried out to a sufficient extent to form a smooth, hard surface with the correct cross-fall, with the stones well knit together, and showing their faces on the surface. The cross section of the newly rolled surface should be frequently checked by the use of a long straight-edge and level to ensure that the cross-fall of 1 in 24 is correctly obtained. No spreading or rolling is to be carried out in frosty weather. When the road cannot be entirely closed to traffic, care should be taken to minimize inconvenience to the travelling public during the progress of the work by coating one-half of the width at one time. No unrolled stone should be left on the road overnight. Care should be taken not to leave a vertical or steep edge of the new coating, but the edge should be thinned out so as to afford an easy passage from the new coating to the old surface. Notice boards warning the public that steam rolling work is in progress should be placed at reasonable distances from each end of the work.

10. Binding.—The binding material should be the best reasonably obtained. It should be either of the same material as the new coating, or of granite, lime-stone, or slag chippings, or, failing these, suitable pit gravel and the largest stone in it should not exceed ¾ in. in its greatest dimension. The binding material is not to be applied until the stones have been tightly rolled, as above described. It should then be spread, watered, and swept over the surface during the final rolling operations, working it from the channels towards the centre so as to fill the interstices or voids between the rolled stones. Care should be taken not to use more binding material or water than is absolutely necessary to ensure proper consolidation. The success of water-bound steam rolling so greatly depends on the quality and quantity of the binding material used that extreme care should be taken in its selection and application.

11. Re-rolling.—In some cases it is advisable that a steam-rolled waterbound macadam surface should be lightly watered and re-rolled from a week to a fortnight after the first rolling.

12. Records.—A careful daily record should be kept of all particulars of the work, the number of men employed, the time occupied, the quantity of material used, the area of new coating finished, and also of the state of the weather and other details.

Appendix to Road Board Specification No. 7.—In preparing for the reconstruction of roads which require a preliminary examination and reformation of contour before a steam-rolled macadam surface can be satisfactorily applied to them, attention should be given to the following points and careful records kept for future reference:

1. The relative levels of the intended road surface and that of the adjoining lands.
2. The means of disposing of surface water by drainage.
3. The nature of the fences.
4. The width of the carriageway and the full width between fences.
5. The gradients of the road.
6. The character and condition of the existing carriageway and indications of any special features of weakness or wear.
7. The cross-section of road from fence to fence.
8. The material previously used for surfacing work and most readily obtainable for road construction and the cost thereof.
9. The requirements as to foundations.
10. The points at which, on account of soft wet clay or bog or marshy sub-soil special means are to be adopted. Good results can be obtained in some cases by supporting the road crust on a layer of dry ashes or clayey gravel, or by spreading heather or faggots, but in each case the local circumstances and conditions must determine the means to be adopted.
11. Whether it is desirable to have footpaths on one or both sides of the road.

LOS ANGELES AQUEDUCT HYDRO-ELECTRIC PROJECT.

The city of Los Angeles has recently approved a bond issue amounting to $357,367 to complete the equipment of the hydro-electric project to be operated in connection with the 250-mile aqueduct by which the city water is brought from Owens Lake, near the Yosemite National Park.

The generating equipment will be installed at Power House No. 1, located at San Franciscedo, 47 miles from Los Angeles, to which point current is sent at 60,000 volts.

In the power house there will be installed three 9,375-kva., 6,600-volt, 50-cycle, three-phase water wheel generators running at 200 r.p.m.; and two 250-kw., 250-volt direct-current water wheel generators used as exciters; ten 3,150-kva., single-phase, 50-cycle oil insulated water-cooled transformers for raising the generator voltage (6,600) to that of the transmission, 60,000.

In the sub-station there will be installed nine 5,000-kva. single-phase, oil insulated water cooled transformers for stepping down the transmission voltage to either 33,000 or 16,000 for secondary distribution.

The contract for the entire equipment was awarded to the Westinghouse Electric & Manufacturing Company.

FEDERAL AID FOR GOOD ROADS.*

By Herbert J. Bowman, C.E., County Clerk and Treasurer, Berlin, Ont.

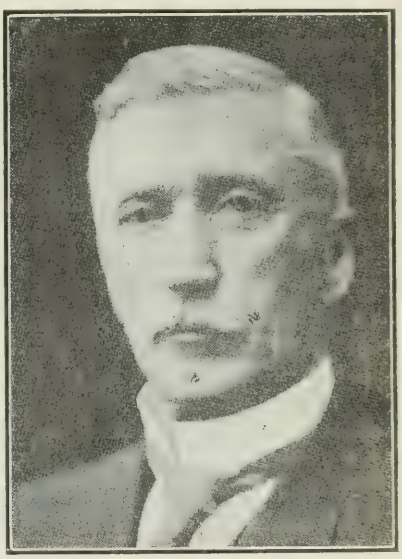
The present Dominion Government came into power committed to the policy of Federal aid for good roads. On this plank of the Halifax platform we can all stand, no matter what may be our party allegiance. In the past, the Canadian press on both sides of politics has uniformly condemned the old statute labor system. In lieu of this relic of pioneer days, a cash payment system is necessary and Federal aid for good roads will command journalistic support in all quarters and the endorsement of public bodies generally.

Raising Money for Roads.—To build good roads requires money, which must ordinarily be raised by taxation. The tax should be borne by the different sections of the community, as far as possible, according to the benefit received by each. Good roads throughout the country benefit both the producer on the land and the consumer in the city, so a portion of the cost should be levied upon the urban as well as upon the rural municipalities. Moreover, the country highways are used more and more by motor cars from the towns and cities and more expensive roads are required for this traffic. For these reasons urban municipalities should contribute towards the construction and maintenance of the highways in the adjoining rural municipalities. In the Province of Ontario, however, as now organized and administered, there is no tax on city municipalities for country roads. A remedy for this resulting injustice is supplied by Federal aid for good roads. Through it all classes will contribute towards the building of the King's highway. The splendid roads of England, France, Germany and other European countries are, as a rule, built and maintained by the national governments, under expert supervision. In the United States the Federal Government has for years maintained the Office of Public Roads in connection with the Department of Agriculture. Through this office, expert engineers are supplied free of charge and object lesson roads are built in those counties assuming county road systems. Large sums are voted by different States for building good roads, and the cities, moreover, not being separated from the counties in which they lie, contribute towards the county rates, so that there the farmers do not carry all the burden of maintaining the highways. The city of Buffalo, for instance, has already contributed towards the building of roads in Erie County over a million dollars, and pays besides, its share of the $50,000,000 voted a few years ago by the State of New York for good roads. For these reasons contributions from the Federal treasury are less necessary in the United States, and yet several bills are now before Congress for this purpose. In Canada, however, no better way can be found to defray the cost of building and maintaining roads than by annual appropriations from the surplus revenue of the Dominion.

Hon. R. L. Borden.

Grants to Provinces.—When the large delegation waited on Premier Borden on February 8th he assured us that the Dominion Government would make substantial grants to the nine provinces for highway improvement. If $1.00 per annum for every man, woman and child is given for this purpose the total sum to be voted by Parliament would be about $8,000,000. This amount could hardly be expended to advantage this year as we are not prepared as yet for such extensive operations, probably one half of this amount would be sufficient. However, if one dollar per head of population is considered a reasonable sum, it will be safe to say that $50,000,000 will be required for good roads within the next six or seven years. To divide this grant fairly between the different provinces should not be a difficult task. Some provinces have greater need of good roads than others. Where agriculture is the chief industry, improved highways are very essential, but where lumbering, mining or the fisheries are principally depended upon, the need is not so great. In the new country, branch lines of railway rather than roads are in great demand. Some of the older provinces have splendid water transportation but require improvements to canals and harbors, the deepening of river channels and other public works. By attention to the peculiar needs of each section Parliament should have no great difficulty in apportioning the good roads grant, those provinces that do not require as much money for improved highway transportation being compensated in some other way.

Effect in Ontario.—On the basis of one dollar per head of population, it would be reasonable to expect the sum of $2,000,000 per annum as our share of Federal aid for Good roads in Ontario. Half of this sum might be used to build and maintain a system of provincial highways, one great road to connect Montreal and Windsor, with branches touching all the counties to be added as soon as possible. New Ontario would continue to be developed by colonization roads as at present, but on a more extensive scale.



Hon. Frank Cochrane.

The county road systems in Ontario should receive the benefit of the balance of the Federal grant, namely, $1,000,000 per year. The provincial grant of one-third for county road work has been found to be entirely too little in the past. Federal aid will enable county roads to be built on a just basis in the future, with the burden shifted from the farmers' backs. In Massachusetts the State Highway Commission builds the roads and the county repays 25 per cent. of the cost. This generous treatment of the farmers, it should be remembered, is given by the State without Federal aid. Surely with Federal aid a certainty, we can better afford to be just to the rural municipalities in Ontario.

County Roads in Ontario.—A fair division of the cost of county roads in future would be: One-half payable by Do-

* Paper read at Ontario Good Roads Convention, Toronto, Feb. 27th, 1912.

minion; one-quarter payable by province; one-quarter payable by county. With forty counties in Old Ontario, this would mean an annual expenditure in the average county of $50,000 per year. One-quarter of this ($12,500) would be added to the county rates, or, if the county council found it necessary, this amount could be raised by debentures guaranteed by the province and sold direct to investors in the mother country instead of being peddled around to our local people at a comparatively high rate of interest.

Conclusion.—Proper supervision of this great national undertaking is absolutely necessary. Let the Dominion Government establish a Highway Commission with expert engineers to advise the provinces how to proceed and to inform Parliament of the results obtained.

Let our Ontario Government establish a Highway Commission or a department with a minister at the head of it. Then employ engineers to assist the counties in building roads adapted to their needs. This will be a simple matter in some counties, but in others it will call for the most careful consideration. Adopt as a motto for the future, "Be sure you are right, then go ahead."

NOTABLE WORK ON THE CATSKILL AQUEDUCT.

The construction work going on in connection with the carrying out of the Catskill Aqueduct project is deservedly attracting widespread attention. It is inevitable that important problems have to be solved when it is proposed to bring an enormous supply of water from a mountain district one hundred miles distant conducting it across a score of valleys some of them several miles in width, as well as across so deep and broad a river as the Hudson. The problems have especial interest for the municipal engineer because of the very character of the enterprise. They have large interest for the concrete engineer for the reason that the construction of the aqueduct is everywhere involving the use of Portland cement and concrete. The steel siphon work should have the earnest attention of the engineer and manufacturer concerned in the possibilities of steel construction. The mining engineer has his interest claimed by the shaft and tunnel construction. Portland cement (in cement mortar or in concrete) plays a most important part in all of this. It is not only involved in the concrete of the cut-and-cover sections, but it is relied on to make possible a protective covering for the inside and outside of the steel siphons. It has been found of exceedingly great value in the sinking of one of the deep working shafts; in fact, it may be questioned whether the sinking of this shaft would not have failed without it. Consider, then, the Rondout pressure tunnel and the steeel siphons.

The Rondout Pressure Tunnel.

The Catskill Aqueduct may be said, if one speaks broadly, to parallel the Hudson River. Consequently, the route cuts across the tributary streams. These are creeks or brooks of no especial importance, so far as size goes. However, they mark the positions of valleys, some of which are a number of miles in width. One of the largest is the valley of Rondout Creek In making the crossing at this point the aqueduct drops far below the surface of the ground, far below the bottom of the creek, and thus makes the 4½ mile passage from one side to the other. A vertical shaft at each end, and a third located at an intermediate point will remain permanent features. In addition, five other shafts were sunk to the tunnel grade in order to facilitate construction. One of these, Construction Shaft No. 4, is 500 feet deep. It is 10 x 22 feet in horizontal section. Eighteen months were occupied in putting down this shaft. It was flooded six times. The strata passed were:—

	Feet.
Glacial drift	6
Helderberg limestone	226
Binnewater sandstone	39
High Falls shale	92
Shawangunk grit	134
Total	497

The trouble with the water came, no doubt, almost altogether from the sandstone and the shale. But the water made its presence felt long before these strata were reached. The site of the shaft included the location where a 4-inch test-hole had been put down. When a depth of about 80 feet had been reached a sudden inrush occurred through this hole filling the shaft half full. The emergency pumping plant had not yet been delivered, so that the contractors were caught unprepared. However, by the use of an air-lift and a couple of sinking pumps the water level was lowered to a point near the bottom. A nipple was driven into the hole and casing attached to it. The purpose was to grout up the hole. In order to carry out this plan a 1-inch pipe was put down to the level of the Shawangunk grit; that is, to the 363-foot level. The water was now permitted to return. Pressures were thus equalized and currents prevented. The grout was made according to the formula 1:1 and poured down the 1-inch pipe. This latter was withdrawn as the grout filled in.

The problem of this one hole was solved in this way. But fears began to be entertained as to whether the ordinary methods of shaftsinking would prove successful. It was understood that there was below a great deal of water under considerable pressure. With subsequent events in mind, it is not difficult to see that a special pumping chamber in the side of the shaft should have been provided before permitting the excavation to pass out of the limestone. This arrangement was made later, but the delay was the source of much trouble. However, excavation went on, and the sandstone was penetrated. At the 260-foot level the amount of incoming water was only about 225 gallons per minute. However, during the drilling of the sump an additional 600 gallons per minute came in suddenly through one of the drill-holes, with the result that the shaft was flooded again. After some trouble the shaft was unwatered, only to be flooded three additional times in as many weeks. Pretty much all this water came in through bore-holes, none of which was probably over two inches in diameter. When the fifth unwatering had been completed the conditions below were known to forbid further progress apart from special precautions. In fact, it had been ascertained that large crevices were a short distance beneath the bottom of the excavation. One of the largest of these crevices was distant only a foot and a half. The size of the crevices ran up to 8 inches. As compared with the 2-inch bore-holes, they promised plenty of trouble.

Grouting up the Crevices.—It was now proposed to deal with the water question by means of grout. Four special machines were set up at the mouth of the shaft. A 2½-inch pipe led down the shaft to the bottom where a 2-inch hose carried the grout to the point of use. At the beginning of operations the grout gave trouble by leaking back. It would come in through the spaces around the pipes and through cracks in the bottom. This difficulty was successfully met by mixing finely ground hose manure with the grout. The manure produced a clogging effect. Some grout was wasted, but success was eventually obtained. In this procedure a

total of 2,900 bags of Portland cement was consumed. When the grout had hardened in the crevices a few more holes were drilled. Water having a head of 65 pounds was found 14 feet below. These holes were soon grouted up, only 60 bags of cement being required.

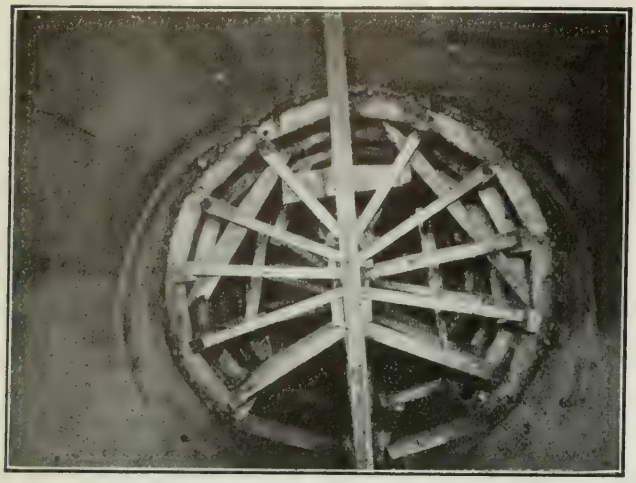
But sinking was not at once resumed. It was deemed advisable to deal further with the question of the water. The grit was now about 100 feet farther down. It was proposed to grout up the intervening water-bearing strata with more grout. Accordingly, six diamond drill-holes were put down to the grit. Half were of the size corresponding to a 1-inch core and half to a 2-inch core. With a pressure of 275 pounds per square inch, these holes were grouted up with 175 bags of cement. Nobody knew whether this small quantity of cement meant that the problem was a small one, or whether it had been only partially solved. It would seem that the thorough application of the method of grouting aheead of the excavation should have been employed sooner; that is, before the water-bearing strata had been penetrated. Sinking was now begun again, and prosecuted until a depth of 320 feet was reached. A couple of collecting rings had been arranged, and many sinking pumps installed in the shaft. The working space was much impeded. Besides, it was difficullt to secure easy, certain and adequate pumping capacity by the use of sinking pumps alone. It was determined to construct a pumping chamber off to one side at the 309-foot level. This chamber was quite large, being 10 feet high and having horizontal dimensions of 17 and 24 feet. Beneath its floor a sump, 5½ feet deep and 16 x 22 feet in area, was arranged. It had a capacity of 14,500 gallons. In the special chamber were installed three Cameron horizontal condensing pumps furnished by the Cameron Pump Works, New York City. These were all the 24 x 10 x 20-inch size, and had a combined capacity of 1,050 gallons per minute. They were run by steam supplied by three 100 horse-power boilers set up at the mouth of the shaft. As the pumps were of the condensing type, this whole arrangement was a possible one. Before the installation of this powerful pumping plant the sixth flooding of the shaft took place. Subsequently no especial difficulty was encountered from the water. More grouting was done, but none of the seams required more than 100 bags of cement, with one exception. When the grit was reached a hole gave trouble, and required 348 bags of cement. The amount of water pumped from this one shaft was 86,181,000,000 foot gallons. The total amount of Portland cement consumed in the grouting operations was 971 barrels.

Bryn Mawr Siphon—Southern End.

The Steel Siphons—Grout Inside, Concrete Outside.—Where the Catskill Aqueduct crosses a very broad valley a permanent vertical shaft is put down on each side, and the two bottoms connected by a more or less horizontal tunnel through the solid rock; but where the valleys are quite narrow, the practice is to make the crossings by means by steel tubes. These are of enormous dimensions. Three parallel tubes are required for each crossing in order to furnish full capacity. Only one is being put in at present—the middle one. There are to be, in all, fourteen steel siphon crossings of an average width of 0.455 mile. This work is divided

into two contracts, one of which is held by the T. A. Gillespie Company, of New York City.

Altogether, the fourteen siphons will require for the single central tube something over six miles of steel pipe.



Indian Brook Siphon, looking north, and showing forms in place or cement mortar lining of steel pipe. Lining is two inches thick. Invert is placed by hand on a preliminary operation,

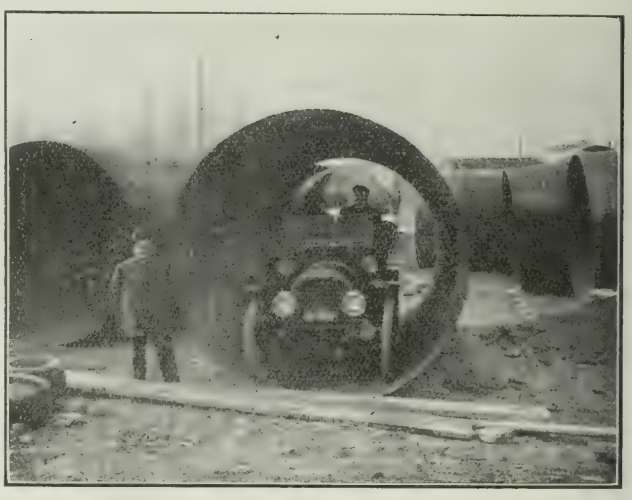
The diameters are 9.50, 9.75 and 11.25 feet. The thicknesses of the steel plates vary from 0.438 to 0.750 inch. The variations in diameter and thickness of plate are made in order to permit a standard capacity to be maintained under varying conditions, and to enable varying bursting pressures to be withstood. The joints are riveted ones. Circular joints are lap-riveted. With the thinnest plates (0.438 inch), the longitudinal seams are also lap-riveted. For plates thicker than 0.500 inch the longitudinal seams are butt-riveted. For the 0.500-inch thickness both methods are employed on longitudinal joints. The butt-riveting is done by bringing the edges together—edge to edge—and then covering the joint, inside and out, with a steel strap. The inner strap is wider than the outer one. The rivets securing the outer strap to the tube are also the central rows of rivets for the wide inner strap. They thus hold together three thicknesses of plate. In addition, two single rows of rivets are arranged outside the narrower strap, holding the tube and the inner strap together. Altogether, six rows of rivets are employed. The two central rows—one row to each side of the joint—have their rivets arranged abreast of each other. The rivets of the rows just outside of these are arranged in staggered positions relative to the two central rows. The two rows outside of all which secure only two thicknesses of plate, have their rivets placed at double the interval used in the other rows.

In crossing the Peekskill Valley over a mile and a quarter of pipe is required. All of it is of the smallest diameter. A short length (139 feet), presumably at the lowest point, is of the thickest plate (0.750 inch); then there is a total of 1,000 feet or more of the 0.688 inch thickness. Apparently no other of the crossings required such thick plate as the 0.750 inch thickness. This will be understood when it is stated that the maximum head at Peekskill is 340 feet—45 per cent. greater than in any other case. It is the widest and the deepest of the steel siphon crossings.

The steel pipe is furnished in 15-foot lengths. A circular joint has, accordingly, to be made every 15 feet. This fact has to be taken into account in the preparations for the reception of the giant tubes. Concrete cradles are arranged at such intervals as to permit the shop and field joints to come between them. The concrete cradles are eight feet or more across, measured transversely the line of the aqueduct, and about three feet wide. The same style is not used everywhere. A typical cradle has, however, a curved depression above to fit the pipe. It is then continued horizontally for a short distance. Underneath, a vertical section across the line of the aqueduct discloses a flat curve. The manner of casting is quite simple. Two bulkheads of the required form are placed on the earthen surface, which has been given the required curvature. The bulkheads are held temporarily in position by a couple of wooden strips nailed across. The concrete is poured in and the upper surface formed by hand. However, a transverse and several longitudinal grooves are desired where cradle and pipe are to come into contact. These are provided by using short lengths of wooden strips. The object of these depressions will appear later.

When the cradles have been cast, the pipe suitably placed, and the field joints made, the entire siphon is filled with water, the pressure being brought to the conditions that are to exist when the aqueduct is in actual service. This is done not merely to test for possible leaks, but especially to give the pipe the exact form it will have when in actual use. While filled thus with water the concrete envelope is put on. This is a proceeding requiring time. During this period it is important that the pressure be maintained at the required point. It is necessary, therefore, not merely to pump the pipe full, but to maintain the pressure night and day. In this and other duties Cameron pumps have been used.

It is necessary, or at least advisable, to clean the surface of the pipe thoroughly preparatory to the application of the concrete envelope. It is possible that the concrete would absorb and take care of a thin coating of rust. But no chances are being taken on that. Removable ribs are employed to hold the lagging in place. At Bryn Mawr narrow wooden strips, making lap joint with each other, were in use upon the writer's visit. The concrete is dumped upon the crest of the pipe. The jacket of concrete completely envelops the tube, except where the cradles themselves are located.



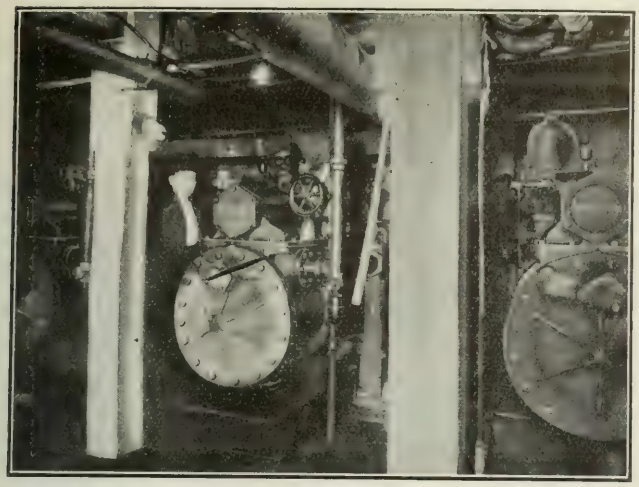
Kensico Siphon—15 ft. Section of 9 ft. 9 in. x 7-16. in. Steel Pipe. Size shown by automobile.

Prior to placing the concrete of the envelope a grout is poured into the grooves arranged on the upper surface of the cradles. Access is gained from the side. This grout fills the system of grooves beneath the steel plate and effects a close joint.

The placing of the interior shell of cement mortar is one of the most interesting and important matters connected with the steel siphon work. This lining is required to have a minimum thickness of two inches and a smooth internal

surface when finished. A little consideration will show that we have here a considerable problem. Of course, any satisfactory solution of the problem must be a commercial one. Considerable experimenting has been done.

A steel form presents, perhaps, the best surface adapted to securing the desired smoothness. It would, perhaps, be



Special pump chamber arranged to one side of shaft at depth of 300 ft. Equipped with three horizontal Cameron pumps.

difficult to provide ribs strong enough, and yet sufficiently flexible, to permit slight variations in form to be made. The tube is not a circle—it is, rather, an ellipse. A device for blowing the grout on to the steel, and thus building up the required thickness was tried for a while. It seemed to put the mortar on satisfactorily, except that it left a rough surface expensive to smooth. On the Gillespie contract wooden forms are used. The bottom of the lining is put in by hand. The remainder—about 270 degrees—is placed at a single pouring when a section of form, perhaps 20 feet long, is ready. This consists of nine segments, each covering about 30 degrees. Each segment is a unit. They are all alike, so that no mistakes can occur in arrangement. Ribs giving strength to one segmental form interlock with ribs of the next one, and so on. The interlocking is secured by providing a tongue or protuberance on one end of a rib and a corresponding notch in the other. The tongue of one rib is placed in a notch of the rib next to it around the circle. We thus get a long rib of 270 degrees. Five struts are now put in place at a number of the 270-degree ribs. These extend from a joint on one side to the joint opposite on the other. They are easily placed and easily taken down. Altogether, there are about twenty such struts used in setting one section of form. The struts contact at each end, not with the joints, but with intervening longitudinals. There is a simplicity and flexibility about this form that makes it quite successful. Metal stops are employed to regulate the distance between form and pipe. When all is ready the pouring is accomplished by means of a tube running up through the roof. This permits the cement mortar to be furnished from an outside point. The tube is arranged at one end of the form. The end selected is the lower one. A hole is left open at the other end to provide a suitable vent. No provision is made for expansion and contraction. It is assumed, perhaps, that with the pipe full of cold water and the exterior well protected there will be but a small variation in temperature.

The concrete on the outside and the cement mortar on the inside are to be considered as having no other service of importance to perform besides that of protecting the steel pipe. Time will alone tell how perfectly this has been accomplished.

CLAY TILE FREIGHT RATES.

The following information has been compiled and is issued by the Department of Physics, Ontario Agricultural College. The tables give the weight of tile and approximate freight rates in Ontario.

The railways state their traffic as so many cents per hundred-weight for a given distance, in car lots, the car to be loaded to its capacity. As the farmer wants to know the freight per 1,000 tile an effort has been made to supply this, as closely as may be. The weight of a tile of given size varies somewhat with the different makers, but those given in Table I. have been determined by actual test and may be taken as fairly representative.

Knowing the freight rate for any distance and the weight of 1,000 tile, the freight per thousand is easily worked out. The results are given in Table II.

Table I.—Approximate Weight of Tile of Various Sizes.

Size of Tile	Weight of one Tile lbs.	Weight of 1,000 Tile lbs.
3 inches	5¼	5,250
4 "	8	8,000
5 "	10½	10,500
6 "	14	14,000
7 "	18	18,000
8 "	22	22,000
10 "	27½	27,500
12 "	33	33,000

Table II.—Approximate Freight Rates of Tile.

Distance in miles	Rate per cwt.	Rates per 1,000 Tile. 3 inches	4 inches	5 inches	6 inches	8 inches	10 inches	12 inches
0—10	3 cents	$1.58	$2.40	$3.16	$ 4.20	$ 6.60	$ 8.25	$ 9.90
10—20	3½ "	1.84	2.80	3.68	4.90	7.70	9.62	11.55
20—30	4 "	2.10	3.20	4.20	5.60	8.80	11.00	13.20

CANADIAN ROAD LAWS.

By E. A. James, B.A. Sc., Engineer for the York Highway Board.

Good roads have become a necessity in Canada, the rapid development of our agricultural districts demands good roads for the output of the farms. The work of our mineral districts necessitates good roads from the mines to the railway station or to the steamboat wharves. The day of the horse drawn freighter is almost gone and the demand now is for roads that will withstand the traffic of vehicles propelled by motor power.

The demand for good roads in Canada is more than necessary, it is imperative.

There are approximately 26,650 miles of steam and electric railroads in Canada to-day. No one knows exactly how many miles of highways there are, but most careful calculation one can make will place it at 1,010,000 miles.

Before taking up the question of building of good roads we would present a resume of the road laws of the various provinces of Canada.

It is necessary that the highway engineer, who has to give one-half of his time to administration work, should know the leading features of road system laws as it is, that he should know the main points in road building.

Good roads may be built under many systems of organizations and control and different systems under different conditions may give equally good results, however, the engineer must be informed on the various systems, so that he may select the best for the condition in which he is working.

The engineer is not a legislator, but he is frequently consulted when legislation is framed, therefore a study of Canadian legislation dealing with Canadian roads is naturally of interest to highways engineers.

Canadian Highway Act.—The most recent and most important legislation dealing with highways in Canada is bill 77, introduced in the House of Commons, Ottawa, by the Hon. Frank Cochrane, Minister of Public Works, in January of this year.

It is entitled: An act to encourage and assist the improvement of Highways, and although it has not yet become law, still it is of such importance that we give the full text of the bill.

> **Bill 77.**—Whereas the highways of Canada constitute an important part of the facilities which are necessary for any efficient national scheme of transportation and inter-communication; and, whereas, with the increasing progress and development of the country it is desirable and expedient to improve and extend the existing highway facilities, and for that purpose to give assistance to the various provinces of Canada: Therefore, his Majesty, by and with the consent of the Senate and House of Commons of Canada, enacts as follows:
>
> 1. This Act may be cited as The Canada Highways Improvement Act.
>
> 2. In this Act the word "Minister" means the Minister of Railways and Canals.
>
> 3. The Governor-in-Council may, in any year, and upon such terms and subject to such conditions as are prescribed by Order-in-Council, grant to any province in aid of the improvement of existing highways or the construction of new highways in such province, or for both such purposes, a subsidy not exceeding such sum as may in such year be voted by Parliament for that purpose.
>
> 4. Any highway for which aid is granted to a province shall be improved or constructed, as the case may be, according to descriptions, conditions, and specifications approved by the Governor-in-Council on the report of the Minister, and specified in each case in an agreement between the Minister and the Government of the province, which agreement the Minister, with the approval of the Governor-in-Council, is hereby empowered to make.
>
> 5. Each highway to be constructed or improved shall be defined and described in such agreement, and provision may be made therein for the future maintenance of such highway in good condition according to a specified standard, and to the satisfaction of the Governor-in-Council.
>
> 6. The Minister, with the approval of the Governor-in-Council, and upon such terms and conditions as are prescribed by Order-in-Council, may undertake the construction of any new highway or the improvement of any existing highway in any province, and may expend in such improvement or construction the whole or any part of the sums voted by Parliament, for such subsidy to that province. Provided, however, that the Minister shall first obtain the necessary authority from the Legislature of such province and the consent of the Lieutenant-Governor-in-Council.

This measure is the first step by the Dominion Government to give aid for the building of the King's highway. Since Confederation the Dominion Government has granted eighty million dollars to build and improve our railways and eighty-eight million two hundred thousand dollars (exclusive of G.T.P.) to construct our canals, but not one cent for highways. With a Canadian Act granting aid to highways, new interest will be taken in the subject and a new impetus given to road-building

Provincial Road Laws.—Each province has its own road law and, as might be expected, the laws vary with the provinces, as the conditions peculiar to those districts warrant.

Prince Edward Island.—Prince Edward Island, with the exception of the city of Charlottetown, and the town of Summerside, has no municipal government of any kind; however, the highways of the province have been placed entirely under the Department of Public Works. For the purposes of administration, the province is divided, by the department, into thirty-eight road divisions, each containing about 100 miles of road. These divisions are under road inspectors, who have a certain amount of machinery under their control to be used on this section. The general soil of Prince Edward Island is of a soft, loamy character, and about 90 per cent. of the roads are earth roads. During 1910 there was spent on the highways about $32,000, or a little over $8.00 a mile.

The Public Road Act of this province, as amended in 1910, contains a clause which provides for tax of $1.00 per head per annum upon all persons between the age of twenty-one and sixty except clergymen and overseers, and a tax of 25 cents per head per annum upon all horses over three years of age, except those used by clergymen and overseers.

During this year a Good Road Association has been formed, and it is expected that the following educational campaign work of constructing permanent highways throughout the provinces will shortly be undertaken.

Nova Scotia.—In the province of Nova Scotia the roads are under the control of the municipalities who have direct control of the statute labor.

The Provincial Government, however, make expenditure upon these highways, dividing their expenditure into two accounts.

(a) Contribution to bridges costing more than $500.00 to construct.

(b) Expenditure on the construction and maintenance of highways constructed by the municipalities under direction of the commissioner of roads.

The municipal councils have no control over the expenditure of these moneys, as all charges are paid from the provincial treasury.

An amount of about $250,000 is assessed by the municipalities under the statute labor law, and the work is carried on under the control of these authorities.

Yearly reports, showing the amount collected or uncollected in each district, are submitted to the road commissioner, and by him to the government, but outside of the regulations of the statute labor law, the government exercises no jurisdiction with regard to statute labor, as this law was enacted after consultation with the wardens of the various counties.

It is proposed to borrow money on capital account and to expend it under the same system as that of larger bridges, that is, under some authority appointed by the government. This is to supplement the present expenditure from revenue which, with 18,000 miles of road to keep up, is insufficient to do more than make the roads passable and to attend to the most urgent cases of reconstruction or the building of new roads.

In 1880 the municipalities had full control of the roads and bridges, but neglected the same, and the government enacted various laws, first, taking over the construction of larger bridges, and secondly, the repair of same; then, thirdly, the construction and repair of smaller bridges, and fourthly, the maintenance of public highways to a great extent.

The expenditure for roads and all structures connected therewith, not included in the foregoing, arising from two sources:

(a) Government grant.

(b) Statute Labor.

The control of the government grant is placed in the hands of a road commissioner appointed by the government, and is apportioned into sums required for the painting and repairs of larger bridges for the construction and repairs of other structures, for the purchasing of road machinery, and according to a scale approved by the government for any construction and repairs of highways in the different municipalities of the province.

The statute labor is entirely in the hands of the municipal councils, and is also expended on the construction and maintenance of the highways, there being a working arrangement between the municipalities and the commissioner of roads in the localities in which the work is performed.

Ontario.—The roads of Ontario in the newer sections are under the control of the Department of Public Works, and are known as colonization roads. When the districts become organized the roads come under the control of the township councils. Township councils have full control of these highways and they maintain them either by statute labor or direct taxation.

In some counties certain roads have been set apart as leading highways, and come under the Highway Improvement Act of Ontario. Under this Act provision has been made that where certain roads are set apart and approved of by the government on being constructed according to the specifications submitted by the province, the province will pay one-third of the cost. So far the department have taken the stand that a grant will only be made to county systems.

Alberta.—Alberta has not yet been divided into rural municipalities, but it is expected that at the present session of the Legislature a Municipality Act will be passed giving rural municipalities control of the highways. Up to the present the Public Works Department of Alberta has had charge of road improvement works.

Where portions of the country are organized into Local Improvement Districts (which is the first step towards municipalities) the Provincial Government frequently makes an expenditure, conditional upon an equal amount being paid by the Local Improvement District, and practically always insisting upon supervision by their engineer, inspector, or general road foreman, as the case may be.

All highway bridges so far in the province of Alberta have been constructed by the government.

Saskatchewan.—The rural highways of Saskatchewan, in settled districts, are under local improvement boards, which usually represent a district of four townships.

In the newer districts roads are under the control of Department of Public Works, and for the construction and maintenance of these roads the government levy a tax of $2.00 per quarter section.

To supplement this sum the government vote a special grant annually, which amounts to approximately a three-quarters of a million dollars. Where the municipality undertakes improvement work which has been sanctioned by the Department of Public Works, the government will pay a subsidy of 25 per cent., provided not more than $1,000.00 is spent in any one year to any one road, and providing that not more than two roads in any municipality receive a grant during the current year.

British Columbia.—In the early days of this province road building was undertaken by military engineers. Later the Department of Public Works undertook the management of the highways and provincial roads are now the main traffic arteries of the provinces.

In road building British Columbia has the advantage of good material with which to build and centralize authority to undertake the work. Five million a year for the next three years is the sum they anticipate spending on highways.

Outside of the towns and cities the roads are largely provincial highways.

CONSISTENCY OF CONCRETE.

A circular letter of inquiry on the subject of the Consistency of Concrete was addressed to the members of the Concrete Institute of Great Britain, in which it was suggested that a specification as drafted would be of service, pending experiments and tests that ought to be made to determine the exact proportion of water to be used in concrete in order to obtain the best mixture. This specification, as now slightly modified by the committee, is as follows:—

Consistency of Concrete.—For mass concrete the quantity of water added to the other constituents shall be sufficient to make a plastic mixture which, after thorough ramming, will quiver like a jelly.

For reinforced concrete the quantity of water added to the other constituents shall be such that the plastic mixture is capable of being rammed into all parts of the moulds and between the bars of the reinforcement.

Note.—In dry or hot weather the quantity of water shall be increased in order to allow for evaporation.

Fifty-eight replies were received, which have been carefully considered by the Reinforced Concrete Practice Standing Committee, who have come to the following conclusions:

1. It is inadvisable to lay down any definite rule as to the percentage of water to be used in mixing concrete, owing

to the varying conditions which obtain. The proposed specification is difficult to improve upon, and seems to meet with general agreement.

2. The strength of concrete apart from any reinforcement increases as the amount of water used in mixing is decreased, this being more particularly the case during the earlier stages of the maturing of the concrete. Eventually the wetter of two mixtures will approach more nearly to the drier in strength.

3. In reinforced concrete, particularly in such portions as may contain a large amount of reinforcing bars or the like placed closely together, it is essential that the concrete should be sufficiently wet to pass between the reinforcing bars, and to thoroughly surround every portion of the steel. This should be ensured even at the expense of having the concrete wetter than would otherwise be desirable.

Where the reinforcement is not very closely spaced it is unnecessary for the concrete to be so wet.

4. Other conditions being the same, the drier the concrete the more quickly will it set and mature. This is of importance when there is any danger of green concrete being attacked by frost.

5. The wetter the concrete the greater is the tendency to contract during the process of setting and maturing. Appreciable contraction may sometimes continue for a period of several years.

6. The committee is divided as to the advisability of determining by some means of mechanical test the exact degree of "wetness" or consistency of concrete after mixing. If some scale of consistency were adopted, it would be possible to specify that concrete for any particular portion of the work should be of such and such a consistency, after mixing. This would not, of course, be at all the same as specifying that any particular amount of water should be used in mixing such concrete owing to differences of atmospheric temperature, aggregate, &c.

The advocates of the institution of some such scale of consistency are of opinion that the Concrete Institute should carry out tests on the subject.

DEFINITION OF ELASTIC LIMIT.

The Engineering Standards Committee of Great Britain gives standard definitions of the terms "yield point" and "elastic limit." The former, specified as "the point where the extension of the bar increases without increase of load," is defined as follows: "The yield point is the load per square inch at which a distinctly visible increase occurs in the distance between gauge points on the test piece, observed by using dividers or at which when the load is increased at a moderately fast rate there is a distinct drop of the testing machine lever, or, in hydraulic machines, of the gauge finger." To this is appended this note: "A steel test piece at the yield point takes rapidly a large increase of extension amounting to more than 1-200th of the gauge length. The point is strongly marked in a stress-strain diagram." The Elastic Limit is defined as "the point at which the extensions cease to be proportional to the loads. In a stress-strain diagram plotted to a large scale it is the point where the diagram ceases to be a straight line and becomes curved," and it is added that "the Elastic Limit can only be determined by the skilful use of very delicate instruments and by the measurement of the extensions for small successive increments of load. It is impossible to determine it in ordinary commercial testing." In a note added by request of the Ships Committee, it is remarked that the committee does not recommend the use of either "Yield Point" or "Elastic Limit" in the standard specifications for ship material, because in regard to the ascertainment of the Yield Point there is considerable divergence of opinion as to the best method of determining it, and all methods involve greater time and care than can be expected in the works. While it is possible in works by careful testing at a greatly reduced speed to obtain the Yield Point in ordinary mild steel and wrought iron, some of the harder steels and other constructional materials have no definite Yield Point at all, and some have no Elastic Limit. Further, it is quite impossible to determine the Elastic Limit in the time available for ordinary commercial testing. In its determination a specially delicate and accurate extensometer must be used, in the hands of a careful and competent observer, and the determination for each test bar would require a considerable time. It is properly a matter to be left to laboratories organized for scientific purposes. The Ships Committee is therefore of opinion that the present method of fixing, by experience, the working stress for any material as a proportion of the ultimate breaking stress, rather than as a proportion of the Elastic Limit or Yield Point, is the best practical method, and it considers that the inclusion in the British Standard Specifications for ship material of tests to ascertain either the Elastic Limit or the Yield Point would not justify the dislocation of the ordinary commercial testing as carried out in the works' test rooms which would thereby be entailed.

STEAM POWER PLANTS.

At the recent convention of the Coal Mining Institute of America, held in Pittsburg, December 19, there was read a paper on "Steam Power Plants," prepared jointly by O. S. Lyford, Jr., consulting engineer, and R. W. Stovel, mechanical engineer, Westinghouse, Church, Kerr Company. The paper read in part as follows:

"Owing to the diversity of fuels used in steam power plants in various sections of the country and the difficulties to be encountered in making comparisons of the values of the different fuels, we have taken Pittsburg coal with a thermal efficiency of 14,000 B.t.u. per pound as a standard for the calculations made.

"As to power plants, the ideal plant would be one that could be planned and made up in the shop, taken down and erected where it was required, but unfortunately this system of building power plants is impracticable from the fact that each plant has its peculiarities and offers different conditions to be met with so that it is very rarely that the same plans would answer for two different plants. As there are power plants for a great variety of purposes, we have, to simplify matters, considered only electric plants for railways and power stations, operated by steam turbines and where bituminous coal is used as fuel. Ten plants of this type have been selected ranging in capacity from 79,000 down to 1,000 kw., located in various parts of the country and operated under a variety of conditions."

Views were shown of foundation plans, floor plans, sectional, exterior and interior views of various plants. From the costs of constructing these plants the authors of the paper had prepared a table giving the maximum and minimum costs of each item of importance entering into the erection and equipment of the plants and the totals showed that the costs ranged from $38 to $83.75 per kw. The cost of boiler installations ranged from $23.15 to $50.25 per horse-power.

"It will be seen that the fuel to be used has been decided, the geographical location of a plant has little to do with the design or equipment, but that the location of the water supply and the method of receiving fuel are important facors; also that a proper design and proper arrangement of the apparatus have more to do with the cost of the plant than any other factor."

The Canadian Engineer

ESTABLISHED 1893.

ISSUED WEEKLY in the interests of the CIVIL, MECHANICAL, STRUCTURAL, ELECTRICAL, MARINE AND MINING ENGINEER, THE SURVEYOR, THE MANUFACTURER, AND THE CONTRACTOR.

HIGH BUILDINGS.

In a recent newspaper report we note that Winnipeg is to have a fifteen-story building. The larger cities in Canada have come to the stage where they must settle their policy with respect to high buildings. At the present time there is little or no restriction of height, and, to our mind, that is a very serious condition.

High buildings tend to cause congestion of traffic, and, while in some cases, such as New York, they are necessary, we doubt very much as to the necessity in Winnipeg. Here the city has plenty of chance to expand and develop, and there is no immediate necessity for very high buildings. The present building by-law in Toronto limits the height to 100 feet above the curb line, except in the case of buildings higher than this, when they must be passed by both the City Architect and the City Council. The city of Montreal has always restricted the height to 130 feet and ten stories above the sidewalk level of the principal front. The committee there, who are now revising these by-laws, propose to keep to the 130 feet, but they may permit eleven stories. Boston keeps within the 130 foot limit. Quebec has no building height restrictions whatever, and the reason for this is that up to the present time there has probably been no necessity for one.

The recent terrible disasters which have overtaken Baltimore, San Francisco, and some of the other American cities has shown the danger of concentration of a number of people in a small area.

The development of fire-breaks prevents the very extensive spread of fire in the congested districts, and the development of sprinkler devices, both inside and outside the building, have aided in protecting individual buildings.

At the same time, it remains an absolute fact that a fire occurring in these very high office buildings is a fearful menace to the inmates. With the increased height comes increased danger, and we believe that modern civilized communities are beginning to appreciate this fact. The only way to safeguard the danger, or at least to minimize it, is to limit the height.

In an address to the Montreal Builders' Exchange Mr. Walter J. Francis, the engineering expert on the Montreal City Building By-laws Committee, said that in his opinion the iron fire escapes on the outside of buildings are a very much over-rated device. These escapes, he said, generally open from windows, through which, in case of fire, smoke and flames are pouring, making the escape-bars red hot like furnace grates.

Aside from the fire danger, there are many other disadvantages from the use of high buildings. Mr. Ernest Flagg, a New York architect, in a recent interview drew attention to some of the abuses flowing from the use of sky scrapers. Mr. Flagg states that in the use of very high buildings the owner perpetrates a serious wrong on his neighbors in depriving them of light. He draws attention to the fact that in many cases the use of high buildings is not only justified, but required. The street plan, however, should be modified by widening. If we double the height of a building we should double the width of streets in order to provide light and the capacity for handling the traffic of the street. He also

lays emphasis on the innate ugliness of the sky scraper, and the difficulty of providing æsthetic treatment in its use. Mr. Flagg states that very often these buildings are a monument of individual or local vanity.

Our cities in Canada are comparatively young, and there seems little reason why high buildings should be allowed now, if adequate transportation facilities in the shape of well-laid-out streets are made. The consequent danger from fire with high buildings is far too serious to allow us to enter on this without first exhausting every other means for the easy handling of business and interchange of traffic.

THE ONTARIO GOOD ROADS ASSOCIATION.

The Ontario Good Roads Association met this week in Toronto. Mayor Geary extended a civic welcome on Monday morning to delegates from all parts of Ontario. It is easy to see the increased interest that is being taken in the good roads question throughout the province by the numbers in attendance at the Convention and the interest taken in the papers read and the discussions thereon.

The Ontario farmer is beginning to appreciate the advantages which will be his from a good system of highways connecting all parts of the province and allowing of easy traffic and intercourse. President Kennedy, in his annual address, expressed gratification that the federal and provincial Governments had recognized the necessity of helping to shoulder the burden of constructing and maintaining the highways. He referred to the vast sums which had been granted as bonuses for railway construction, and said that it was now time for bonuses to the highways system.

Mr. Kennedy stated that in his opinion the clause in the bill now before the Dominion Government, which allows the Federal Government to build roads in the province, is a mistake. He said: "The federal highway is only a trunk road; it would not reach the individual. What Ontario wants, especially the farmer, is a provincial system of main highways reaching from county town to county town. Such a system would comprise nearly 2,500 miles."

In our opinion Mr. Kennedy is right, for there will certainly be difficulty in administering that clause of the bill which states that the Minister, with the approval of the Governor-in-Council, may undertake the construction of any new highway or the improvement of any existing highway in any province, and may expend on such improvement or construction the whole or any part of the sums voted by parliament for such subsidy to that province. There is a qualifying clause in the bill which states that the Minister shall first obtain the necessary authority from the legislature of such province and the consent of the Lieutenant-Governor-in-Council.

The administration of these funds must be more closely brought under the control of the several provinces, while the administration, experimental work and general organization of the good roads question should be placed in the hands of a Dominion Good Roads Department.

EDITORIAL COMMENT.

Among the letters written to the Editor as a result of the recent editorial on the "Employment of Engineers," the following ideas predominate: In all work of a public nature the best man should be secured for the position. In many cases where foreign expert advice has been secured it would have been found, if a close examination had been made, that the best advice could have been obtained from a Canadian. We are rather inclined at times in this country to underrate the capabilities of our own people; in other words, "the prophet in his own country."

* * * *

The Department of Industrial Research of the University of Pittsburg, is entering upon the study of the smoke problem in the broadest possible manner. The Department is taking as the chief lines of investigation the effect of smoke on health, plant life and buildings. The increased cost of living, due to damage and dirt caused by smoke, and the legal, as well as the engineering side of the question, are also to be considered. Each of these investigations will be carried on by one or more men, each a specialist in his line. The Department hopes that by co-ordinating these various researches it will be possible to obtain valuable technical as well as scientific data. They will, at least, be able to establish the status of the problem on a scientific basis. The University of Pittsburg are to be congratulated on the attitude they have taken in this matter. If our Canadian universities, through their Applied Science Departments, would devote more time to the chemical, industrial and manufacturing problems throughout the country, in place of fostering the theoretic side of pure science to the neglect of the practical, they would be doing more towards deserving private and government aid.

CORRECTION.

In our issue of February 15th we published an article, entitled "Underground Street Construction," and neglected to credit our contemporary, "Good Roads." We are glad at this time to correct the omission.

TORONTO BOARD OF TRADE.

An important address was delivered recently by Mr. R. S. Gourlay, retiring president of the Toronto Board of Trade, at the annual meeting. It reviewed at length the work of the year and was characteristic for its broadminded tone. Among the important matters before the Board during 1911 was the proposal to enlarge and deepen the Welland Canal. An impetus had been given to the agitation started four years ago by the improvement of the Erie Canal in the State of New York at a cost of $100,000,000. The work of the board in 1910 made the deepening of the Welland Canal more than a by-word. It became an important issue before the Government, and disappointment was felt when the estimates for 1911 did not include an appropriation for the commencement of the enterprise. The project also had the endorsement of the Associated Boards of Trade of Ontario.

THE PRINCIPLES OF SPECIFICATION AND AGREEMENT WRITING.

By C. R. Young, A.M. Can. Soc. C.E.

(Registered in accordance with the Copyright Act.)

Third Article.

SUBJECT-MATTER OF THE SPECIFICATIONS.

Because of their content, the clauses of the specifications fall naturally into two classes—Specific and General. In the former are treated all those matters referring to the extent, character and details of the work, while the latter concern the authority, privileges and procedure of the parties or their representatives in office and field. In order of development the specific clauses come first, for on them the major portion of the time given to the preparation of the specifications must be spent. It is often possible to adopt general clauses from previous specifications with little alteration, but the specific clauses must generally be specially prepared for each piece of work, due to the changed conditions and types of construction.

SPECIFIC CLAUSES.

Among the most important matters to be covered in the specific clauses of the specifications for a typical piece of construction work are the following:—

(1) Extent of the Work.
(2) Dimensions and Proportions.
(3) Accompanying and Contemplated Drawings.
(4) Capacity or Required Performance.
(5) Designing Rules.
(6) Classification and Estimating Rules.
(7) Quality of Materials.
(8) Quality of Workmanship.
(9) Methods of Construction.
(10) Inspection.
(11) Condition of Finished Work.
(12) Acceptance Tests.
(13) Cleaning up.

The order to be pursued in the writing of a specification is not necessarily that outlined above, nor would these matters be wholly treated in individual sections under the foregoing captions. For example, the required character of the cement, concrete, brick, stone, timber and steel for a piece of work would not ordinarily be completely covered in one section, entitled "Quality of Materials," but rather under headings denoting the class of construction, as "Concrete Work," "Brick Work," "Stone Work," "Carpentry," and "Structural Steel." By this means the specification is divided up into portions corresponding to the various trades or constructional interests affected—a proceeding which greatly facilitates the preparation of bids by contractors.

(1) **Extent of the Work.**—In the interests of convenience and in furtherance of accuracy in bidding, the amount of the work to be done should be described both as a whole and in detail.

The portion containing the description of the work as a whole is probably the most important single clause in the specification, and generally it is the first of the specific clauses. In it is given a concise and clear statement of the extent and scope of the work, from which the Contractor is able, not only to decide whether it is worth his while to bid, but to roughly check his total estimate and ascertain if all the important operations and the principal quantities have been provided for. This clause should, therefore, contain the following information:—

(a) An enumeration of all the important steps or operations involved in the work:—

(b) Mention of any portion of the work to be performed by the Owner or by another Contractor, or any materials to be supplied by these parties.

(c) A statement of quantities, if practicable.

The following clause, from a slightly-altered contract covering the construction of both the substructure and the superstructure of a steel bridge, is typical of the method of describing the work as a whole where a statement of quantities is not given:—

> "The work comprised in this Contract will include taking down the old superstructure and abutments; neatly piling the old material at the side of the road near the bridge in such a manner as not to obstruct traffic; erecting and maintaining a temporary bridge, utilizing the material from the old bridge in so far as practicable; excavating materials to the depth required for foundation beds; filling in the excavated spaces around the abutments up to the original ground level; the construction of two concrete abutments; making earth approach fills behind the abutments; placing a gravel surface upon this filling; procuring, fabricating and erecting a steel superstructure of thirty (30) feet clear span on the completed abutments; constructing a reinforced concrete floor after the steel superstructure has been erected; removing all falsework, surplus material and débris from the site of the work and leaving the structure complete and ready for traffic."

In general, the embodiment of a schedule of quantities in the description of the work as a whole is to be desired. It is of especial assistance to the Contractor where the project is of considerable extent or where many different classes of work are covered in the contract. The waste of time and effort involved in requiring every bidder to compute the plan quantities is most regrettable. These calculations should be made by the engineer, and the responsibility for their accuracy should be assumed by him quite as much as the responsibility for computations of distances, stresses or sections.

The extent of each kind of work should also be described in detail in a section of the specification devoted to that purpose. Detail should, of course, be excluded from the description of the work as a whole, since the value of that portion of the specification largely depends upon its conciseness. An illustration of a detailed provision fixing the extent of a particular kind of work would be the following abridged clause from a contract for the construction of a sewer:—

> "The ground on the line of the proposed sewer is to be excavated in open cutting. . . . the depth of the bottom of such excavation being in all cases as shown on the profile, or as laid down by the Engineer, as he may think necessary to secure a firm foundation and proper level. . . . For pipe sewers the cutting at the bottom is to be at least eight (8) inches wider than the pipe to allow the haunches to be well packed and rammed with suitable tamping irons."

Where several classes of work of a similar character occur in a piece of construction the limits of these classes should be carefully defined, as the lines of demarcation

of concrete of different mixtures in the same structure. This may be done by stating the elevations of the top and bottom faces of each class or by mentioning the various portions of the structure in which a given class is to be used.

In most contracts there are operations to be performed and material to be supplied for which the Contractor receives his compensation in the prices for other work. Thus, embankment work and back-filling are commonly paid for in the prices for excavation. The remuneration for sheet-piling, cofferdamming, pumping and baling is received in the prices for excavation or masonry. Falsework, forms and staging are covered in the price for the permanent work, whether it be steel, concrete or masonry. Obviously, therefore, the contract should indicate such of these items as may be paid for directly and such as are covered by prices for a different class of work. For all those paid for in the first manner, prices should be set down in the agreement, and those covered in the second way should be so described in the specific clauses of the specifications.

It is particularly desirable that each kind of work for which a price is named in the agreement should be clearly described in a paragraph of the specifications. The applicability of these prices to any particular work in question may thus be readily judged, and numerous disputes over extras thereby obviated.

(2) **Dimensions and Proportions.**—There are many facts of a dimensional nature which it is not convenient to put on the plans, and which, because of their amenability to written descriptions, are inserted in the specifications. In grading contracts, it is very common to specify in writing the width of cutting and embankment and the side slopes in both cuts and fills. The engineer who prepares a general specification for a bridge without accompanying plans, sets forth the required clear span, clear width of roadway, clearance above the bridge floor, and, for the abutment and pier heights, the clearance above some specified water level. Certain limiting sizes or sections for main material, and also for details, are commonly established in any structural specification. The municipal engineer specifies a certain minimum relation of the width of a sewer trench to the internal horizontal diameter of the sewer.

(3) **Accompanying and Contemplated Drawings.**—For purposes of identification, and also for ease of reference, a list of the accompanying drawings is incorporated in the contract. Preferably it is placed in the specifications rather than in the agreement. If either the Owner or the Contractor is to prepare future detail drawings for use in the construction of the work, this fact should be stated, and the stipulation made that no work based upon such drwaings is to be executed until they have been approved by the engineer. While the inclusion of future illustrative or detail drawings in a contract is permissible and consistent with the legal requirements, it is not allowable to include drawings establishing principal or primary features unless such drawings are in existence at the time of signing of the contract.

In the section devoted to drawings it is customary to state that figured dimensions are to be given precedence over scaled ones, except in case of obvious clerical error, when the one most consistent with the contract as a whole is to be adopted.

(4) **Capacity or Required Performance.**—Specifications for most engineering work set forth some particular performance of which the construction must be capable. If it be a bridge, building or analogous structure, it must safely accommodate certain superimposed loads, and frequently this must be done without exceeding a specified deflection. In addition to this the structure must be able to resist at the same time the stresses brought to bear upon it by impact, wind, traction and temperature changes. If the contract concerns a pumping engine, the latter is required to pump so many gallons of water per pound of dry steam or per one hundred pounds of coal. A generator must have an output of so many kilowatts, and be able to carry a stated overload without a rise of temperature of over a certain number of degrees. For certain kinds of construction, as pavements and sidewalks, it is frequently required that the work shall show a specified endurance against wear, or resist the various destructive agencies brought to bear upon it for a stated term of years without abnormal deterioration.

(5) **Designing Rules.**—Where the work is to be designed by the Contractor on the basis of general data submitted by the engineer, comprehensive designing rules must be inserted in the specifications. Even when the work is designed by the engineer himself, and only the details are worked out by the Contractor, it is necessary to include certain of such rules for the guidance of the Contractor in designing the details.

The stipulations respecting design may be conveniently divided into three classes: (a) Assumptions of design, (b) permissible stresses, and (c) approved details. The assumptions of design include such matters as effective spans of beams, girders, floor-beams and trusses; effective depth of plate girders and reinforced concrete T-beams; maximum allowable slenderness ratio for columns; width of slab to be counted as flange in a T-beam, and many other matters of the kind. Under permissible stresses are set forth the intensities of tensile, compressive, bending, shearing, bearing and torsion stresses, or combinations of them, which must not be exceeded for the various materials to be employed in the work. In order that objectionable details may be obviated, the engineer should be careful to fix by the specification the character of the details desired, in so far as it is possible to do so. It is, therefore, common to specify such matters as that plate girder flanges shall be made up of a certain minimum percentage of area in the angles; that compression chords shall be of box rather than T-section; that rockers or bolsters shall be used for the bearings for all spans over a certain length; that reinforcement steel shall be spaced, lapped or spliced in a certain manner; that the lower ends of longitudinal rods in reinforced concrete columns shall rest on bearing plates, and many other analogous requirements respecting details.

FOREST FIRE WASTE.

An important phase of Canada's fire waste was discussed by Mr. Percy Robertson, insurance broker and fire prevention engineer, at a recent meeting of the Toronto Insurance Institute. His address was illustrated with stereopticon views.

As an illustration of the extent of past losses by fire in our forests, he referred to estimates made by the Dominion one-half of the original timber supply has already been destroyed by fire; that government stumpage dues at the moderate rate of 50c per 1,000 feet on the timber destroyed would have yielded a revenue of $1,000,000,000; and that for every foot of timber ever cut in Canada, seven have been destroyed by fire. Serious forest fires continue to occur, and such a state of affairs demands the adoption of vigorous and intelligent preventive measures.

COUNTY ROAD CONSTRUCTION IN ONTARIO.*

By W. A. McLean, Provincial Engineer of Highways, Ontario.

Canadians are universally proud of their country, and of its resources of mine, forest and field. The possession of such a splendid land carries with it certain obligations to do as our forefathers have done, to make and leave it a better place to live in than we found it. A tremendous energy is now being exerted to develop Canada, and one of the striking phases is in relation to agriculture, in which, more and more, improvement is being sought, and the farmers of the country have entered upon what we trust may be a long period of advancement and prosperity.

To aid in the development of Canada one of the larger enterprises has been the construction of steam railways. Over 25,000 miles have been built, and the capital invested exceeds 1,500 millions. So intent have the Canadian people been upon securing railway facilities, that land and cash subsidies and other aid have been granted by the Federal and Provincial Governments, and municipal corporations, amounting in value to about 600 millions; or nearly one-half the capital investment in railway construction.

Railway construction has been supplemented by canals, harbors and steamship lines so that, at a very large cost, the people of Canada have generously provided for an important section of the transportation problem. Having great resources, and having magnificent railway and waterway facilities, we are still very much like the man who had a wagon and a team of horses, but was without harness; and so neither wagon nor horses were of any use. The need of Ontario and of Canada to-day, is a system of good roads that will harness our railway and waterway team to the farm, whereby both the farm and the greater transportation systems will attain their full value and usefulness.

At the present time the roads of Ontario are largely maintained by the townships with statute labor, while important construction is being carried on by county councils. Proposals of Federal aid suggest that the road organization of the Province may be broadened out so as to include three classes, township, county, and state, on a basis such as has created the good roads systems of older countries and of a number of the American States.

The actual building of good roads is an important engineering problem too seldom recognized as such, with the result that there is and has been much wasted energy. But while it is important to know how to build roads, the great object is to so organize as to get the work done. If proper organization is provided, all the rest will be taken care of by this organization; and such an organization will include or create skilled planning, efficient direction of labor, and good finance. It is needless to condemn the ordinary township system of statute labor. It has done much good in the past under pioneer conditions, but its faults are fully apparent to those who are accustomed to good business organization. What is advocated and urged, is that a more effective system be put in its place. The abolition of statute labor is advisable only because there is a more efficient, more equitable and more business-like system available. It is useless to commute statute labor and retain fifty or 150 pathmasters to scatter the money. It is a mistake to commute or abolish statute labor, and then appoint councillors as commissioners to spend the money in such a way as to make votes instead of roads.

The best method is to follow the organization of every well-conducted business. Appoint one capable road superintendent to act as manager for the council, in supervising and carrying out works of road improvement. Centralize responsibility in one man, the council acting as a board of directors.

As previously stated, the abolition of statute labor is merely a means to an end—to make room for a better system, and every municipal councillor can render his best service by having a thorough understanding of the principles that constitute that better system. By doing away with statute labor entirely, levying a rate with ordinary taxes for road purposes, centralizing responsibility in one efficient road overseer, creating a policy of building permanent bridges and culverts, doing some permanent road work each year, and caring for all roads by the systematic use of the log drag—by such measures can a township council fully justify the abolition of statute labor.

While township councils are doing something to patch and repair roads, the most important construction is now being carried on by county councils under the Highway Improvement Act. A tree is known by its fruit; and "a corrupt tree cannot bring forth good fruit." The results under county road systems have been more or less satisfactory according to the efficiency of the organization under which they were produced. The same principles as those outlined for townships are applicable to county work; and the most important factor is the ability of the county road superintendent. There are now twenty counties of the Province building systems of roads. Returns have not been made for last year, but to the end of 1910 their expenditure has been as follows:—

Road construction and supervision	$1,790,253.91
Permanent bridges	476,765.49
Machinery, plant, etc.	145,743.32
Special grants to townships, villages and towns	112,674.84
Toll roads purchased	155,997.98
Total expenditure	$2,681,435.54

Of the foregoing total expenditure of $2,681,435.54 the Provincial contribution under the Highway Improvement Act has been one-third, or $893,811.84. Of one million dollars set aside by the Legislature in 1901 under the Highway Improvement Act there remains, after meeting payments for the work of 1910, the sum of $106,188.16; which sum will not be sufficient to meet the Provincial obligations to be incurred by work carried out during the year 1911, but as you are aware, a second million has been appropriated by the Provincial Government to continue this work.

Main Roads.—Broken stone roads of the best class have been reduced to a few well-defined types, through more than a century of experience in England, France, Germany, and on this continent. The true macadam road has a well-drained and crowned earth sub-grade, over which is spread a uniform coating of broken stone of about two and one-half inches in greatest dimension. The Telford road has a foundation of flat quarry stones, placed by hand, on edge, the angular points being chipped off by hammer and wedged into the interstices; and over all is spread a coating of fine broken stone, in thickness about one-third of the total depth of the stone surface. The earth sub-grade is flat, and larger stones are used at the centre of the road, with smaller at the sides, to give the desired camber. The roads built by Tresaguet in France were substantially the same as the Telford road, and are usually included with it. In the French type, the sub-grade was cambered, and the foundation stones of uniform depth. A distinct type of foundation is that developed in Massachusetts, in which there is a slightly V-shaped sub-grade with a filling of cobble or field stone, a method which is claimed to give, more effectively than other types, the desirable under-drainage.

*Address delivered to Ontario Good Roads Association, February 27, 1912.

Experience has shown the superiority of roads with a foundation, such as the Telford type, in reducing the cost of maintenance under heavy traffic. Settlement is more uniform, and defective drainage is less destructive. If the natural sub-soil is strongly supporting, such as a dry, well-cemented gravel, the foundation may be omitted with saving of cost. Whether the Telford or Massachusetts type of foundation be followed, the writer believes that local material suitable for either should largely govern.

County roads in Canada cannot, as a rule, follow closely English, French, German, or other standard, but must be built with a view to the particular needs of this continent, and of the locality. The need in Ontario is a long mileage, to be built as rapidly as possible, through districts where population is comparatively sparse, where there may be little or no roadmaking material, and the available expenditure necessarily restricted by these and other conditions.

European engineers would undoubtedly, if it were possible to reconstruct many of their roads, lay them with foundations, but the cost is prohibitive. No more is it practicable on this continent to build any but the most heavily-traveled roads with expensive foundations. Instead, it is necessary to depend on good drainage, carefully maintained, to keep the sub-soil dry and strong enough to sustain the road surface.

Drainage.—Bridges have to be strong enough for the maximum load, and with waterway enough for the maximum freshet. So roadbeds should have sufficient drainage for the severest test, which in northern countries is a period of thaw in the early spring, lasting usually for two or three weeks. If sub-soil drainage is sufficient for that test, no break-up of the road crust need be feared at other seasons.

Old specifications for roads built in Canada before the period of railway construction, required open drains on each side of the road, with bottom at least two feet below the crown. In many places the drain was deeper; and hills or spouty places were under-drained by trenches filled with field stone. Such roads have stood the test of time, and may be accepted as the standard of drainage required for the north; except that tile under-drains are taking the place of open ditches where they would otherwise be dangerous, unsightly, or difficult to maintain. Drains of porous farm tile keep the sub-soil at its dryest and prevent uneven settlement of the road crust into mud, which is as destructive to a road when below the surface as when on the surface. Some counties of Ontario are using tile drains the full length of all their roads. Others use them only on wet and spouty hills, on level land which is exceptionally wet and retentive, or where the open drain would otherwise have to be dangerously deep to give sufficient fall and outlet. In the last case, the tile may carry some surface drainage, receiving it in catch-basins.

Grading and Surfacing.—Closely associated with drainage is the grading of the road. Before a road is surfaced it should be brought to grades that insure permanence. Hills should be cut down, low places filled, and the earth work brought to a substantial turnpike. The road surface will need renewal, but the grade, if properly made, will outlast even the bond issue. On roads of a secondary class elaborate surveys are unnecessary. A good foreman can obtain easy-flowing gradients by grading from point-to-point, but should have an engineer's stakes and profiles in cases of extensive cuts and fills, new locations, tile drains, or doubtful surface drainage.

Roads laid on an earth foundation should be given a higher crown when newly constructed than is desirable for perfect condition. Settlement will assuredly occur, and unless the road is too high to begin with, it will become too flat. A county road as commonly built, which in two or three years has settled to the desirable camber, will give the greatest degree of durability, with least expense for maintenance. One inch to the foot from centre to gutter or edge of shoulder, for a completed, rolled road, will meet ordinary conditions. With a circular cross-section, the greatest part of the fall is on the earth shoulders.

The cost of a road, unless earth-work and drainage is of an exceptional kind, will depend on the width and depth of broken stone used. Wide, flat roads are desirable, but narrow roads with a good camber cost less to build, and much less to maintain, unless a highly organized system of maintenance is created. We have, for this class of road, found an earth grade twenty-four feet wide, shoulder to shoulder, to meet most conditions, which may be reduced to eighteen or twenty feet for least traffic. With shoulders six feet wide, the stone is commonly put on from eight to twelve feet wide. The consolidated depth of metal on county roads is based on eight inches for a moderately strong clay or loam sub-soil. This is modified according to the anticipated amount of traffic and quality of stone to resist wear; the maximum concentrated wheel loads, local tire widths, and wheel diameters, bond of road metal and consequent distributing effect of the metal crust, the supporting strength of the sub-grade and opportunity for drainage.

Bituminous binders may be justified on heavily-traveled suburban roads of this class, but present practice in Canada tends to oiling as a preservative and dust preventive, owing to the less first cost of water-bound macadam.

Binder.—The durability of a road is largely dependent on the binder and the cementing qualities of the stone dust, in producing a waterproof surface—if tar or other bituminous binder is not used. We are strongly in favor of the use of stone screenings as opposed to sand, and have very rarely found gravel or sand sufficiently clean, coarse, and sharp to satisfactorily take the place of screenings as a binder. Wherever practicable, stone screenings are to be recommended, particularly the screenings of certain classes of limestone; the superior cementing qualities of which make it better road metal than its degree of toughness would justify. Limestone screenings are exceedingly useful with water-washed gravel, or with broken granite or trap.

Coursing Stone.—A uniform grade of stone, rather fine, is desirable in finishing the surface, and is necessary where a very hard stone such as trap is employed, but this may be sought at considerably increased cost, and is not always necessary to suitable results. It adds to the cost of a road to spread the stone in several layers. Municipalities using portable crushers will find a rotary screen with two sizes of mesh very satisfactory. This will produce (1) "tailings," or the stone too large to pass through the screen; (2) the middle course, a uniform grade to form the main body of the road, and (3) "screenings" to bond and finish the surface. The tailings should be spread in the bottom of the road, and covered to the required depth with the uniform grade; and this, after rolling, may be lightly coated with screenings and rolled. If a very tough stone, such as trap, the screenings may be such as will pass a one-inch mesh, or a one and one-half inch mesh if limestone, and the uniform grade of stone may be two-inch for trap, and three-inch for limestone, with the screenings removed. Crushing and handling are cheapened by this system, and, for water-bound roads, a smooth surface results.

Local Material.—Trap or other tough rock brought from a distance by rail in preference to the use of soft local material, may be justifiable for surfacing heavily-traveled main roads; but it is a safe rule, if applied with discretion, that local material, if it exists, should be used. Much will depend on the teaming required but for moderate wagon hauls up to two miles, on highways of the second and third classes, the writer has commonly found gravel roads being built for

$100 per mile for each foot in width of metal. If local broken stone is used, the cost is, all things equal, about doubled, or $200 to $300 per foot, and if imported by rail, about $300 to $400 per foot. Taking, then, a road not requiring much grading, and with eight feet of metal and eight inches in consolidated depth, the cost might be stated, for cheap construction, at $800 or $1,000 a mile for a gravel road; $1,600 to $2,400 a mile for a road built of local crushed stone, and $2,400 to $3,200 per mile if the stone is brought in by rail. These prices are for the cheapest class of road that can be built, and the main roads of the province should have a much heavier type of construction.

Gravel Roads.—Gravel in general is inferior to broken stone as a road material, but if of a reasonable quality, is suitable for roads of the third-class—township roads—and for many market roads of the second class, but unless of exceptional quality is deficient for heavy traffic. The rounded pebbles do not take the mechanical clasp that pertains to fragments of broken stone, while the sand which it usually contains is not equal to stone screenings as a binder. It may contain lime or iron, improving its bonding qualities, but as a rule it is not waterproof, and ruts readily in wet weather, especially if it contains sand, clay, or loam in excess.

The best quality of gravel is of varying sized grain up to two inches in greatest dimension, with only sufficient fine material to fill the voids between pebbles. It should be clean and made up largely of a uniform grade of pebbles—qualities rarely found in natural pit gravel. Gravel pits containing a mass of large stones and boulders should be treated as rock, and put through a crusher. Gravel which is not coarse, but which is "dirty," should be screened to remove the excess of sand or clay. A rotary screen may be used, operated by steam power. The gravel can be drawn in wagons to an elevated platform, dumped into a hopper from which it passes through the rotary screen, and from the screen to an elevated bin, from which the screened gravel is again loaded into wagons to be taken to the road. By means of the elevated bins the expense of shoveling into wagons is saved, the time of teams and teamsters is saved, and a well arranged plant will, under favorable circumstances, pay for crushing and screening. This is particularly the case if a pit near the work can be used rather than to team better material a long distance.

Methods.—The methods of construction will largely determine the cost. Machine work is cheaper than manual labor. The cross-section adopted should, therefore, permit the maximum amount of machine construction. Particularly for the cheaper class of roads, the grading machine, in treating with old locations, should do most of the earth work, supplemented with wheeled and drag scrapers. The cheapest and best plan, in our experience, has been to make the earth sub-grade, shoulder to shoulder between ditches, almost flat, or with a central rise of about three inches for a twenty-four foot grade. When this is rolled the stone is spread to the desired width in the centre, then with the grading machine, earth is drawn from the shoulders to support the stone, thus completing the camber. The stone is rolled dry to level the surface, the screenings are spread, sprinkled, and rolled till consolidated. To grade the road and then excavate a central channel to receive the metal is a more expensive method, and is apt, for roads without a foundation, to place the stone too low for good drainage, producing what may be termed a "water-logged" road. Instead of the camber and turnpike being high enough to allow for settlement, it is apt to be made too low and flat.

Rolling.—As distinguished from earlier road making, modern construction has been largely influenced by machinery, especially grading machines, rock crushers, and road rollers. The smaller municipalities of Canada commonly use graders and crushers, but the purchase of a steam roller is too often delayed. It is to be pointed out that the cost of a roller is by no means an additional expense, since rolling effects economy in several ways. Coarser stone can be used in a road that is rolled, so that the cost of crushing is reduced. With coarser stone, the road is stronger to resist wear, and is more securely bonded than if first rutted and mixed with mud. Less stone is required in a rolled road, as loose stone is largely forced down into the mud before the surface becomes waterproof, or is knocked to the ditches by traffic. Without rolling, roads demand attention for one or two years, to rake the stone to place from time to time; the earth shoulders have to be restored and leveled where cut up and destroyed by traffic, new material has to be added to fill hollows and ruts. By rolling the sub-grade, the wet or weak spots are developed, which can be drained or filled with earth and again rolled to produce a uniform foundation; thereby reducing the stone which the road would otherwise absorb. Long lines of loose stone left for traffic to consolidate are a most objectionable obstruction to travel, and bring road building into disrepute. On the other hand, a road built with a heavy roller is a complete work, in perfect condition when finished. Rolled roads are a revelation to those who have been accustomed to and who expect only old-time methods and results. For economy, service, and to popularize the work, rolling should be regarded as essential for every class of gravel and stone roads.

BUILDING FIGURES.

The past year was another one of active building operations and the fact that this condition was general is additional proof of national rather than sectional progress during 1911. The building of warehouses, factories, office blocks was a marked feature, while there was no slackening in the demand for residences. The current year will probably witness the construction of a considerable number of workmen's cottages in all parts of the country.

The following statistics show the value of building operations during the past two years, in 20 selected cities and towns:—

City or town.	1910.	1911.
Brandon	$1,224,385	$1,142,939
Calgary	5,589,594	12,907,638
Edmonton	2,161,356	4,328,960
Fort William	2,381,125	3,078,010
Halifax	471,140	548,734
Hamilton	2,604,605	4,255,730
Lethbridge	1,210,810	1,033,380
London	805,074	1,036,880
Montreal	15,815,859	14,657,210
Ottawa	3,040,350	2,997,610
Peterborough	517,958	345,372
Port Arthur	1,062,616	597,705
Regina	2,351,288	5,089,340
St. Thomas	286,650	285,515
Sydney	347,554	495,642
Toronto	21,127,783	24,250,000
Vancouver	13,150,365	17,652,642
Victoria	2,271,095	4,026,315
Windsor	392,040	739,515
Winnipeg	15,106,450	17,600,000

The value of the building permits issued last year as a rule exceeded the value of the previous year. The most remarkable increases were at Calgary and Regina, which more than doubled their figures. Large gains were also made at Hamilton, Toronto, Vancouver, Windsor, and Winnipeg.

PERMANENT STRUCTURES.*

By James S. Bell, C.E.

Permanent structures as applied to municipal public works are those structures which, when properly built, will remain and fulfil the requirements for which they were intended for the longest possible period. It is not possible to build structures that will stand forever. They are all subject to wear and decay. The whole object is to get a material at reasonable cost, that will, when placed in position, stand the ordinary wear and tear of vehicular or other traffic, and the action of the elements as long as possible without excessive repairs.
